mfxU8 **integer**

Integer part of correction element.

mfxU8 **mantissa**

Fractional part of correction element.

mfxU8 **reserved[6]**

Reserved for future extension.

mfxCamVignetteCorrectionParam

struct **mfxCamVignetteCorrectionParam**

A structure that defines Camera Vignette Correction Parameters.

Public Members

mfxCamVignetteCorrectionElement **R**

Red correction element.

mfxCamVignetteCorrectionElement **G0**

Green top correction element.

mfxCamVignetteCorrectionElement **B**

Blue Correction element.

mfxCamVignetteCorrectionElement **G1**

Green bottom correction element.

mfxU32 **reserved[4]**

Reserved for future extension.

mfExtCamVignetteCorrection

struct **mfExtCamVignetteCorrection**

A hint structure that configures Camera Vignette Correction filter.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_VIGNETTE_CORRECTION.

mfU32 **Width**

Width of Correction Map 2D buffer in *mfCamVignetteCorrectionParam* elements.

mfU32 **Height**

Height of Correction Map 2D buffer in *mfCamVignetteCorrectionParam* elements.

mfU32 **Pitch**

Pitch of Correction Map 2D buffer in *mfCamVignetteCorrectionParam* elements.

mfU32 **reserved[7]**

Reserved for future extension.

mfCamVignetteCorrectionParam ***CorrectionMap**

2D buffer of *mfCamVignetteCorrectionParam* elements.

mfU64 **reserved1**

Reserved for alignment on 32bit and 64bit.

union *mfExtCamVignetteCorrection::*[anonymous] [**anonymous**]

mfExtCamBayerDenoise

struct **mfExtCamBayerDenoise**

A hint structure that configures Camera Bayer denoise filter.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_BAYER_DENOISE.

mfU16 **Threshold**

Level of denoise, legal values: [0:63].

mfU16 **reserved[27]**

Reserved for future extension.

mfExtCamColorCorrection3x3

struct **mfExtCamColorCorrection3x3**

A hint structure that configures Camera Color correction filter.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_COLOR_CORRECTION_3X3.

mfxF32 **CCM**[3][3]

3x3 dimension matrix providing RGB Color Correction coefficients.

mfxU32 **reserved**[32]

Reserved for future extension.

mfExtCamPadding

struct **mfExtCamPadding**

A hint structure that configures Camera Padding.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_PADDING.

mfxU16 **Top**

Specify number of padded columns respectively. Currently only 8 pixels supported for all dimensions..

mfxU16 **Bottom**

Specify number of padded columns respectively. Currently only 8 pixels supported for all dimensions..

mfxU16 **Left**

Specify number of padded rows respectively. Currently only 8 pixels supported for all dimensions..

mfxU16 **Right**

Specify number of padded rows respectively. Currently only 8 pixels supported for all dimensions..

mfxU32 **reserved**[4]

Reserved for future extension.

mfxExtCamPipeControl

struct **mfxExtCamPipeControl**

A hint structure that configures camera pipe control.

Public Members

mfxExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_PIPECONTROL.

mfxU16 **RawFormat**

Specifies one of the four Bayer patterns defined in mfxCamBayerFormat enumeration.

mfxU16 **reserved1**

Reserved for future extension.

mfxU32 **reserved[5]**

Reserved for future extension.

mfxCamFwdGammaSegment

struct **mfxCamFwdGammaSegment**

A structure that specifies forward gamma segment.

Public Members

mfxU16 **Pixel**

Pixel value.

mfxU16 **Red**

Corrected Red value.

mfxU16 **Green**

Corrected Green value.

mfxU16 **Blue**

Corrected Blue value.

mfExtCamFwdGamma

struct **mfExtCamFwdGamma**

A hint structure that configures Camera Forward Gamma Correction filter.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_FORWARD_GAMMA_CORRECTION.

mfU16 **reserved**[19]

Reserved for future extension.

mfU16 **NumSegments**

Number of Gamma segments.

mfCamFwdGammaSegment ***Segment**

Pointer to Gamma segments array.

mfU64 **reserved1**

Reserved for future extension.

mfExtCamLensGeomDistCorrection

struct **mfExtCamLensGeomDistCorrection**

A hint structure that configures Camera Lens Geometry Distortion and Chroma Aberration Correction filter.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_LENS_GEOM_DIST_CORRECTION.

mfF32 **a**[3]

Polynomial coefficients a for R/G/B

mfF32 **b**[3]

Polynomial coefficients b for R/G/B

mfF32 **c**[3]

Polynomial coefficients c for R/G/B

mfF32 **d**[3]

Polynomial coefficients d for R/G/B

mfU16 **reserved**[36]

Reserved for future extension.

mfxCam3DLutEntry

struct **mfxCam3DLutEntry**
A structure that defines 3DLUT entry.

Public Members

mfxU16 **R**
R channel

mfxU16 **G**
G channel

mfxU16 **B**
B channel

mfxU16 **Reserved**
Reserved for future extension.

mfxExtCam3DLut

struct **mfxExtCam3DLut**
A hint structure that configures Camera 3DLUT filter.

Public Members

mfxExtBuffer **Header**
Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_3DLUT.

mfxU16 **reserved[10]**
Reserved for future extension.

mfxU32 **Size**
LUT size, defined in MFX_CAM_3DLUT17/33/65_SIZE enumeration.

mfxCam3DLutEntry ***Table**
Pointer to *mfxCam3DLutEntry*, size of each dimension depends on LUT size, e.g. LUT[17][17][17] for 17x17x17 look up table.

mfxU64 **reserved1**
Reserved for future extension.

10.5.3 Enumerator Reference

Angle

The Angle enumerator itemizes valid rotation angles.

enumerator **MF_X_ANGLE_0**
0 degrees.

enumerator **MF_X_ANGLE_90**
90 degrees.

enumerator **MF_X_ANGLE_180**
180 degrees.

enumerator **MF_X_ANGLE_270**
270 degrees.

BitstreamDataFlag

The BitstreamDataFlag enumerator uses bit-ORed values to itemize additional information about the bitstream buffer.

enumerator **MF_X_BITSTREAM_NO_FLAG**
The bitstream doesn't contain any flags.

enumerator **MF_X_BITSTREAM_COMPLETE_FRAME**
The bitstream buffer contains a complete frame or complementary field pair of data for the bitstream. For decoding, this means that the decoder can proceed with this buffer without waiting for the start of the next frame, which effectively reduces decoding latency. If this flag is set, but the bitstream buffer contains incomplete frame or pair of field, then decoder will produce corrupted output.

enumerator **MF_X_BITSTREAM_EOS**
The bitstream buffer contains the end of the stream. For decoding, this means that the application does not have any additional bitstream data to send to decoder.

BPSEIControl

The BPSEIControl enumerator is used to control insertion of buffering period SEI in the encoded bitstream.

enumerator **MF_X_BPSEI_DEFAULT**
encoder decides when to insert BP SEI.

enumerator **MF_X_BPSEI_IFRAME**
BP SEI should be inserted with every I-frame

BRCStatus

The BRCStatus enumerator itemizes instructions to the encoder by `mfxExtBrc::Update`.

enumerator **MF_X_BRC_OK**

CodedFrameSize is acceptable, no further recoding/padding/skip required, proceed to next frame.

enumerator **MF_X_BRC_BIG_FRAME**

Coded frame is too big, recoding required.

enumerator **MF_X_BRC_SMALL_FRAME**

Coded frame is too small, recoding required.

enumerator **MF_X_BRC_PANIC_BIG_FRAME**

Coded frame is too big, no further recoding possible - skip frame.

enumerator **MF_X_BRC_PANIC_SMALL_FRAME**

Coded frame is too small, no further recoding possible - required padding to `mfxBRCFrameStatus::MinFrameSize`.

BRefControl

The BRefControl enumerator is used to control usage of B frames as reference in AVC encoder.

enumerator **MF_X_B_REF_UNKNOWN**

Default value, it is up to the encoder to use B-frames as reference.

enumerator **MF_X_B_REF_OFF**

Do not use B-frames as reference.

enumerator **MF_X_B_REF_PYRAMID**

Arrange B-frames in so-called “B pyramid” reference structure.

ChromaFormatIdc

The ChromaFormatIdc enumerator itemizes color-sampling formats.

enumerator **MF_X_CHROMAFORMAT_MONOCHROME**

Monochrome.

enumerator **MF_X_CHROMAFORMAT_YUV420**

4:2:0 color.

enumerator **MF_X_CHROMAFORMAT_YUV422**

4:2:2 color.

enumerator **MF_X_CHROMAFORMAT_YUV444**

4:4:4 color.

enumerator **MF_X_CHROMAFORMAT_YUV400**

Equal to monochrome.

enumerator **MF_X_CHROMAFORMAT_YUV411**
4:1:1 color.

enumerator **MF_X_CHROMAFORMAT_YUV422H**
4:2:2 color, horizontal sub-sampling. It is equal to 4:2:2 color.

enumerator **MF_X_CHROMAFORMAT_YUV422V**
4:2:2 color, vertical sub-sampling.

enumerator **MF_X_CHROMAFORMAT_RESERVED1**
Reserved.

enumerator **MF_X_CHROMAFORMAT_JPEG_SAMPLING**
Color sampling specified via *mf_xInfoMF_X::SamplingFactorH* and *SamplingFactorV*.

ChromaSiting

The ChromaSiting enumerator defines chroma location. Use bit-OR'ed values to specify the desired location.

enumerator **MF_X_CHROMA_SITING_UNKNOWN**
Unspecified.

enumerator **MF_X_CHROMA_SITING_VERTICAL_TOP**
Chroma samples are co-sited vertically on the top with the luma samples.

enumerator **MF_X_CHROMA_SITING_VERTICAL_CENTER**
Chroma samples are not co-sited vertically with the luma samples.

enumerator **MF_X_CHROMA_SITING_VERTICAL_BOTTOM**
Chroma samples are co-sited vertically on the bottom with the luma samples.

enumerator **MF_X_CHROMA_SITING_HORIZONTAL_LEFT**
Chroma samples are co-sited horizontally on the left with the luma samples.

enumerator **MF_X_CHROMA_SITING_HORIZONTAL_CENTER**
Chroma samples are not co-sited horizontally with the luma samples.

CodecFormatFourCC

The CodecFormatFourCC enumerator itemizes codecs in the FourCC format.

enumerator **MF_X_CODEC_AVC**
AVC, H.264, or MPEG-4, part 10 codec.

enumerator **MF_X_CODEC_HEVC**
HEVC codec.

enumerator **MF_X_CODEC_MPEG2**
MPEG-2 codec.

enumerator **MFX_CODEC_VC1**
VC-1 codec.

enumerator **MFX_CODEC_VP9**
VP9 codec.

enumerator **MFX_CODEC_AV1**
AV1 codec.

enumerator **MFX_CODEC_JPEG**
JPEG codec

CodecLevel

The CodecLevel enumerator itemizes codec levels for all codecs.

enumerator **MFX_LEVEL_UNKNOWN**
Unspecified level.

H.264 Level 1-1.3

enumerator **MFX_LEVEL_AVC_1**

enumerator **MFX_LEVEL_AVC_1b**

enumerator **MFX_LEVEL_AVC_11**

enumerator **MFX_LEVEL_AVC_12**

enumerator **MFX_LEVEL_AVC_13**

H.264 Level 2-2.2

enumerator **MFX_LEVEL_AVC_2**

enumerator **MFX_LEVEL_AVC_21**

enumerator **MFX_LEVEL_AVC_22**

H.264 Level 3-3.2

enumerator **MFX_LEVEL_AVC_3**

enumerator **MFX_LEVEL_AVC_31**

enumerator **MFX_LEVEL_AVC_32**

H.264 Level 4-4.2

enumerator **MFX_LEVEL_AVC_4**
enumerator **MFX_LEVEL_AVC_41**
enumerator **MFX_LEVEL_AVC_42**

H.264 Level 5-5.2

enumerator **MFX_LEVEL_AVC_5**
enumerator **MFX_LEVEL_AVC_51**
enumerator **MFX_LEVEL_AVC_52**

H.264 Level 6-6.2

enumerator **MFX_LEVEL_AVC_6**
enumerator **MFX_LEVEL_AVC_61**
enumerator **MFX_LEVEL_AVC_62**

MPEG2 Levels

enumerator **MFX_LEVEL_MPEG2_LOW**
enumerator **MFX_LEVEL_MPEG2_MAIN**
enumerator **MFX_LEVEL_MPEG2_HIGH**
enumerator **MFX_LEVEL_MPEG2_HIGH1440**

VC-1 Level Low (Simple and Main Profiles)

enumerator **MFX_LEVEL_VC1_LOW**
enumerator **MFX_LEVEL_VC1_MEDIAN**
enumerator **MFX_LEVEL_VC1_HIGH**

VC-1 Advanced Profile Levels

enumerator **MFX_LEVEL_VC1_0**

enumerator **MFX_LEVEL_VC1_1**

enumerator **MFX_LEVEL_VC1_2**

enumerator **MFX_LEVEL_VC1_3**

enumerator **MFX_LEVEL_VC1_4**

HEVC Levels

enumerator **MFX_LEVEL_HEVC_1**

enumerator **MFX_LEVEL_HEVC_2**

enumerator **MFX_LEVEL_HEVC_21**

enumerator **MFX_LEVEL_HEVC_3**

enumerator **MFX_LEVEL_HEVC_31**

enumerator **MFX_LEVEL_HEVC_4**

enumerator **MFX_LEVEL_HEVC_41**

enumerator **MFX_LEVEL_HEVC_5**

enumerator **MFX_LEVEL_HEVC_51**

enumerator **MFX_LEVEL_HEVC_52**

enumerator **MFX_LEVEL_HEVC_6**

enumerator **MFX_LEVEL_HEVC_61**

enumerator **MFX_LEVEL_HEVC_62**

AV1 Levels

enumerator **MFX_LEVEL_AV1_2**

enumerator **MFX_LEVEL_AV1_21**

enumerator **MFX_LEVEL_AV1_22**

enumerator **MFX_LEVEL_AV1_23**

enumerator **MFX_LEVEL_AV1_3**

enumerator **MFX_LEVEL_AV1_31**

enumerator **MFX_LEVEL_AV1_32**

enumerator **MFX_LEVEL_AV1_33**

enumerator **MFX_LEVEL_AV1_4**

enumerator **MFX_LEVEL_AV1_41**

enumerator **MFX_LEVEL_AV1_42**
enumerator **MFX_LEVEL_AV1_43**
enumerator **MFX_LEVEL_AV1_5**
enumerator **MFX_LEVEL_AV1_51**
enumerator **MFX_LEVEL_AV1_52**
enumerator **MFX_LEVEL_AV1_53**
enumerator **MFX_LEVEL_AV1_6**
enumerator **MFX_LEVEL_AV1_61**
enumerator **MFX_LEVEL_AV1_62**
enumerator **MFX_LEVEL_AV1_63**
enumerator **MFX_LEVEL_AV1_7**
enumerator **MFX_LEVEL_AV1_71**
enumerator **MFX_LEVEL_AV1_72**
enumerator **MFX_LEVEL_AV1_73**

CodecProfile

The CodecProfile enumerator itemizes codec profiles for all codecs.

enumerator **MFX_PROFILE_UNKNOWN**
Unspecified profile.

H.264 Profiles

enumerator **MFX_PROFILE_AVC_BASELINE**
enumerator **MFX_PROFILE_AVC_MAIN**
enumerator **MFX_PROFILE_AVC_EXTENDED**
enumerator **MFX_PROFILE_AVC_HIGH**
enumerator **MFX_PROFILE_AVC_HIGH10**
enumerator **MFX_PROFILE_AVC_HIGH_422**
enumerator **MFX_PROFILE_AVC_CONSTRAINED_BASELINE**
enumerator **MFX_PROFILE_AVC_CONSTRAINED_HIGH**

AV1 Profiles

enumerator **MFX_PROFILE_AV1_MAIN**

enumerator **MFX_PROFILE_AV1_HIGH**

enumerator **MFX_PROFILE_AV1_PRO**

VC-1 Profiles

enumerator **MFX_PROFILE_VC1_SIMPLE**

enumerator **MFX_PROFILE_VC1_MAIN**

enumerator **MFX_PROFILE_VC1_ADVANCED**

VP8 Profiles

enumerator **MFX_PROFILE_VP8_0**

enumerator **MFX_PROFILE_VP8_1**

enumerator **MFX_PROFILE_VP8_2**

enumerator **MFX_PROFILE_VP8_3**

VP9 Profiles

enumerator **MFX_PROFILE_VP9_0**

enumerator **MFX_PROFILE_VP9_1**

enumerator **MFX_PROFILE_VP9_2**

enumerator **MFX_PROFILE_VP9_3**

H.264 Constraints

Combined with H.264 profile, these flags impose additional constraints. See the H.264 specification for the list of constraints.

enumerator **MFX_PROFILE_AVC_CONSTRAINT_SET0**

enumerator **MFX_PROFILE_AVC_CONSTRAINT_SET1**

enumerator **MFX_PROFILE_AVC_CONSTRAINT_SET2**

enumerator **MFX_PROFILE_AVC_CONSTRAINT_SET3**

enumerator **MFX_PROFILE_AVC_CONSTRAINT_SET4**

enumerator **MFX_PROFILE_AVC_CONSTRAINT_SET5**

JPEG Profiles

enumerator **MF_X_PROFILE_JPEG_BASELINE**
Baseline JPEG profile.

CodingOptionValue

The CodingOptionValue enumerator defines a three-state coding option setting.

enumerator **MF_X_CODINGOPTION_UNKNOWN**
Unspecified.

enumerator **MF_X_CODINGOPTION_ON**
Coding option set.

enumerator **MF_X_CODINGOPTION_OFF**
Coding option not set.

enumerator **MF_X_CODINGOPTION_ADAPTIVE**
Reserved.

ColorFourCC

The ColorFourCC enumerator itemizes color formats.

enumerator **MF_X_FOURCC_NV12**
NV12 color planes. Native format for 4:2:0/8b Gen hardware implementation.

enumerator **MF_X_FOURCC_NV21**
Same as NV12 but with weaved V and U values.

enumerator **MF_X_FOURCC_YV12**
YV12 color planes.

enumerator **MF_X_FOURCC_IYUV**
Same as YV12 except that the U and V plane order is reversed.

enumerator **MF_X_FOURCC_I420**
Alias for the IYUV color format.

enumerator **MF_X_FOURCC_I422**
Same as YV16 except that the U and V plane order is reversed

enumerator **MF_X_FOURCC_NV16**
4:2:2 color format with similar to NV12 layout.

enumerator **MF_X_FOURCC_YUY2**
YUY2 color planes.

enumerator MFX_FOURCC_RGB565

2 bytes per pixel, uint16 in little-endian format, where 0-4 bits are blue, bits 5-10 are green and bits 11-15 are red.

enumerator MFX_FOURCC_RGBP

RGB 24 bit planar layout (3 separate channels, 8-bits per sample each). This format should be mapped to D3DFMT_R8G8B8 or VA_FOURCC_RGBP.

enumerator MFX_FOURCC_RGB4

RGB4 (RGB32) color planes. BGRA is the order, 'B' is 8 MSBs, then 8 bits for 'G' channel, then 'R' and 'A' channels.

enumerator MFX_FOURCC_BGRA

Alias for the RGB4 color format.

enumerator MFX_FOURCC_P8

Internal color format. The application should use the following functions to create a surface that corresponds to the Direct3D* version in use.

For Direct3D* 9: IDirectXVideoDecoderService::CreateSurface()

For Direct3D* 11: ID3D11Device::CreateBuffer()

enumerator MFX_FOURCC_P8_TEXTURE

Internal color format. The application should use the following functions to create a surface that corresponds to the Direct3D* version in use.

For Direct3D 9: IDirectXVideoDecoderService::CreateSurface()

For Direct3D 11: ID3D11Device::CreateTexture2D()

enumerator MFX_FOURCC_P010

P010 color format. This is 10 bit per sample format with similar to NV12 layout. This format should be mapped to DXGI_FORMAT_P010.

enumerator MFX_FOURCC_I010

10-bit YUV 4:2:0, each component has its own plane.

enumerator MFX_FOURCC_I210

10-bit YUV 4:2:2, each component has its own plane.

enumerator MFX_FOURCC_P016

P016 color format. This is 16 bit per sample format with similar to NV12 layout. This format should be mapped to DXGI_FORMAT_P016.

enumerator MFX_FOURCC_P210

10 bit per sample 4:2:2 color format with similar to NV12 layout.

enumerator MFX_FOURCC_BGR4

RGBA color format. It is similar to MFX_FOURCC_RGB4 but with different order of channels. 'R' is 8 MSBs, then 8 bits for 'G' channel, then 'B' and 'A' channels.

enumerator MFX_FOURCC_A2RGB10

10 bits ARGB color format packed in 32 bits. 'A' channel is two MSBs, then 'R', then 'G' and then 'B' channels. This format should be mapped to DXGI_FORMAT_R10G10B10A2_UNORM or D3DFMT_A2R10G10B10.

enumerator MFX_FOURCC_ARGB16

10 bits ARGB color format packed in 64 bits. 'A' channel is 16 MSBs, then 'R', then 'G' and then 'B' channels. This format should be mapped to DXGI_FORMAT_R16G16B16A16_UINT or D3DFMT_A16B16G16R16 formats.

enumerator MFX_FOURCC_ABGR16

10 bits ABGR color format packed in 64 bits. 'A' channel is 16 MSBs, then 'B', then 'G' and then 'R' channels. This format should be mapped to DXGI_FORMAT_R16G16B16A16_UINT or D3DFMT_A16B16G16R16 formats.

enumerator MFX_FOURCC_R16

16 bits single channel color format. This format should be mapped to DXGI_FORMAT_R16_TYPELESS or D3DFMT_R16F.

enumerator MFX_FOURCC_AYUV

YUV 4:4:4, AYUV color format. This format should be mapped to DXGI_FORMAT_AYUV.

enumerator MFX_FOURCC_AYUV_RGB4

RGB4 stored in AYUV surface. This format should be mapped to DXGI_FORMAT_AYUV.

enumerator MFX_FOURCC_UYVY

UYVY color planes. Same as YUY2 except the byte order is reversed.

enumerator MFX_FOURCC_Y210

10 bit per sample 4:2:2 packed color format with similar to YUY2 layout. This format should be mapped to DXGI_FORMAT_Y210.

enumerator MFX_FOURCC_Y410

10 bit per sample 4:4:4 packed color format. This format should be mapped to DXGI_FORMAT_Y410.

enumerator MFX_FOURCC_Y216

16 bit per sample 4:2:2 packed color format with similar to YUY2 layout. This format should be mapped to DXGI_FORMAT_Y216.

enumerator MFX_FOURCC_Y416

16 bit per sample 4:4:4 packed color format. This format should be mapped to DXGI_FORMAT_Y416.

enumerator MFX_FOURCC_BGRP

BGR 24 bit planar layout (3 separate channels, 8-bits per sample each). This format should be mapped to VA_FOURCC_BGRP.

enumerator MFX_FOURCC_XYUV

8bit per sample 4:4:4 format packed in 32 bits, X=unused/undefined, 'X' channel is 8 MSBs, then 'Y', then 'U', and then 'V' channels. This format should be mapped to VA_FOURCC_XYUV.

enumerator MFX_FOURCC_ABGR16F

16 bits float point ABGR color format packed in 64 bits. 'A' channel is 16 MSBs, then 'B', then 'G'

and then 'R' channels. This format should be mapped to DXGI_FORMAT_R16G16B16A16_FLOAT or D3DFMT_A16B16G16R16F formats..

ContentInfo

The ContentInfo enumerator itemizes content types for the encoding session.

enumerator **MF_X_CONTENT_UNKNOWN**

enumerator **MF_X_CONTENT_FULL_SCREEN_VIDEO**

enumerator **MF_X_CONTENT_NON_VIDEO_SCREEN**

enumerator **MF_X_CONTENT_NOISY_VIDEO**

Corruption

The Corruption enumerator itemizes the decoding corruption types. It is a bit-OR'ed value of the following.

enumerator **MF_X_CORRUPTION_NO**

No corruption.

enumerator **MF_X_CORRUPTION_MINOR**

Minor corruption in decoding certain macro-blocks.

enumerator **MF_X_CORRUPTION_MAJOR**

Major corruption in decoding the frame - incomplete data, for example.

enumerator **MF_X_CORRUPTION_ABSENT_TOP_FIELD**

Top field of frame is absent in bitstream. Only bottom field has been decoded.

enumerator **MF_X_CORRUPTION_ABSENT_BOTTOM_FIELD**

Bottom field of frame is absent in bitstream. Only top field has been decoded.

enumerator **MF_X_CORRUPTION_REFERENCE_FRAME**

Decoding used a corrupted reference frame. A corrupted reference frame was used for decoding this frame. For example, if the frame uses a reference frame that was decoded with minor/major corruption flag, then this frame is also marked with a reference corruption flag.

enumerator **MF_X_CORRUPTION_REFERENCE_LIST**

The reference list information of this frame does not match what is specified in the Reference Picture Marking Repetition SEI message. (ITU-T H.264 D.1.8 dec_ref_pic_marking_repetition)

Note: Flag MF_X_CORRUPTION_ABSENT_TOP_FIELD/MF_X_CORRUPTION_ABSENT_BOTTOM_FIELD is set by the AVC decoder when it detects that one of fields is not present in the bitstream. Which field is absent depends on value of bottom_field_flag (ITU-T* H.264 7.4.3).

DeinterlacingMode

The DeinterlacingMode enumerator itemizes VPP deinterlacing modes.

enumerator **MFx_DEINTERLACING_BOB**
BOB deinterlacing mode.

enumerator **MFx_DEINTERLACING_ADVANCED**
Advanced deinterlacing mode.

enumerator **MFx_DEINTERLACING_AUTO_DOUBLE**
Auto mode with deinterlacing double frame rate output.

enumerator **MFx_DEINTERLACING_AUTO_SINGLE**
Auto mode with deinterlacing single frame rate output.

enumerator **MFx_DEINTERLACING_FULL_FR_OUT**
Deinterlace only mode with full frame rate output.

enumerator **MFx_DEINTERLACING_HALF_FR_OUT**
Deinterlace only Mode with half frame rate output.

enumerator **MFx_DEINTERLACING_24FPS_OUT**
24 fps fixed output mode.

enumerator **MFx_DEINTERLACING_FIXED_TELECINE_PATTERN**
Fixed telecine pattern removal mode.

enumerator **MFx_DEINTERLACING_30FPS_OUT**
30 fps fixed output mode.

enumerator **MFx_DEINTERLACING_DETECT_INTERLACE**
Only interlace detection.

enumerator **MFx_DEINTERLACING_ADVANCED_NOREF**
Advanced deinterlacing mode without using of reference frames.

enumerator **MFx_DEINTERLACING_ADVANCED_SCD**
Advanced deinterlacing mode with scene change detection.

enumerator **MFx_DEINTERLACING_FIELD_WEAVING**
Field weaving.

ErrorTypes

The ErrorTypes enumerator uses bit-ORed values to itemize bitstream error types.

enumerator **MFX_ERROR_NO**
No error in bitstream.

enumerator **MFX_ERROR_PPS**
Invalid/corrupted PPS.

enumerator **MFX_ERROR_SPS**
Invalid/corrupted SPS.

enumerator **MFX_ERROR_SLICEHEADER**
Invalid/corrupted slice header.

enumerator **MFX_ERROR_SLICEDATA**
Invalid/corrupted slice data.

enumerator **MFX_ERROR_FRAME_GAP**
Missed frames.

enumerator **MFX_ERROR_JPEG_APP0_MARKER**
Invalid/corrupted APP0 marker.

enumerator **MFX_ERROR_JPEG_APP1_MARKER**
Invalid/corrupted APP1 marker.

enumerator **MFX_ERROR_JPEG_APP2_MARKER**
Invalid/corrupted APP2 marker.

enumerator **MFX_ERROR_JPEG_APP3_MARKER**
Invalid/corrupted APP3 marker.

enumerator **MFX_ERROR_JPEG_APP4_MARKER**
Invalid/corrupted APP4 marker.

enumerator **MFX_ERROR_JPEG_APP5_MARKER**
Invalid/corrupted APP5 marker.

enumerator **MFX_ERROR_JPEG_APP6_MARKER**
Invalid/corrupted APP6 marker.

enumerator **MFX_ERROR_JPEG_APP7_MARKER**
Invalid/corrupted APP7 marker.

enumerator **MFX_ERROR_JPEG_APP8_MARKER**
Invalid/corrupted APP8 marker.

enumerator **MFX_ERROR_JPEG_APP9_MARKER**
Invalid/corrupted APP9 marker.

enumerator **MFx_ERROR_JPEG_APP10_MARKER**
Invalid/corrupted APP10 marker.

enumerator **MFx_ERROR_JPEG_APP11_MARKER**
Invalid/corrupted APP11 marker.

enumerator **MFx_ERROR_JPEG_APP12_MARKER**
Invalid/corrupted APP12 marker.

enumerator **MFx_ERROR_JPEG_APP13_MARKER**
Invalid/corrupted APP13 marker.

enumerator **MFx_ERROR_JPEG_APP14_MARKER**
Invalid/corrupted APP14 marker.

enumerator **MFx_ERROR_JPEG_DQT_MARKER**
Invalid/corrupted DQT marker.

enumerator **MFx_ERROR_JPEG_SOFO_MARKER**
Invalid/corrupted SOF0 marker.

enumerator **MFx_ERROR_JPEG_DHT_MARKER**
Invalid/corrupted DHT marker.

enumerator **MFx_ERROR_JPEG_DRI_MARKER**
Invalid/corrupted DRI marker.

enumerator **MFx_ERROR_JPEG_SOS_MARKER**
Invalid/corrupted SOS marker.

enumerator **MFx_ERROR_JPEG_UNKNOWN_MARKER**
Unknown Marker.

ExtendedBufferID

The ExtendedBufferID enumerator itemizes and defines identifiers (BufferId) for extended buffers or video processing algorithm identifiers.

enumerator **MFx_EXTBUFF_THREADS_PARAM**
mfExtThreadsParam buffer ID.

enumerator **MFx_EXTBUFF_CODING_OPTION**
This extended buffer defines additional encoding controls. See the *mfExtCodingOption* structure for details. The application can attach this buffer to the structure for encoding initialization.

enumerator **MFx_EXTBUFF_CODING_OPTION_SPSPPS**
This extended buffer defines sequence header and picture header for encoders and decoders. See the *mfExtCodingOptionSPSPPS* structure for details. The application can attach this buffer to the *mfVideoParam* structure for encoding initialization, and for obtaining raw headers from the decoders and encoders.

enumerator MFX_EXTBUFF_VPP_DONOTUSE

This extended buffer defines a list of VPP algorithms that applications should not use. See the *mfxExtVPPDoNotUse* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for video processing initialization.

enumerator MFX_EXTBUFF_VPP_AUXDATA

This extended buffer defines auxiliary information at the VPP output. See the *mfxExtVppAuxData* structure for details. The application can attach this buffer to the *mfxEncodeCtrl* structure for per-frame encoding control.

enumerator MFX_EXTBUFF_VPP_DENOISE2

The extended buffer defines control parameters for the VPP denoise filter algorithm. See the *mfxExtVPPDenoise2* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for video processing initialization.

enumerator MFX_EXTBUFF_VPP_3DLUT

See the *mfxExtVPP3DLut* structure for more details.

enumerator MFX_EXTBUFF_VPP_SCENE_ANALYSIS

Reserved for future use.

enumerator MFX_EXTBUFF_VPP_PROCAMP

The extended buffer defines control parameters for the VPP ProcAmp filter algorithm. See the *mfxExtVPPProcAmp* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for video processing initialization or to the *mfxFrameData* structure in the *mfxFrameSurface1* structure of output surface for per-frame processing configuration.

enumerator MFX_EXTBUFF_VPP_DETAIL

The extended buffer defines control parameters for the VPP detail filter algorithm. See the *mfxExtVPPDetail* structure for details. The application can attach this buffer to the structure for video processing initialization.

enumerator MFX_EXTBUFF_VIDEO_SIGNAL_INFO

This extended buffer defines video signal type. See the *mfxExtVideoSignalInfo* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for encoding initialization, and for retrieving such information from the decoders. If video signal info changes per frame, the application can attach this buffer to the *mfxFrameData* structure for video processing.

enumerator MFX_EXTBUFF_VIDEO_SIGNAL_INFO_IN

This extended buffer defines video signal type. See the *mfxExtVideoSignalInfo* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for the input of video processing if the input video signal information changes in sequence base.

enumerator MFX_EXTBUFF_VIDEO_SIGNAL_INFO_OUT

This extended buffer defines video signal type. See the *mfxExtVideoSignalInfo* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for the output of video processing if the output video signal information changes in sequence base.

enumerator MFX_EXTBUFF_VPP_DOUSE

This extended buffer defines a list of VPP algorithms that applications should use. See the *mfxExtVPPDoUse* structure for details. The application can attach this buffer to the structure for video processing initialization.

enumerator MFX_EXTBUFF_AVC_REFLIST_CTRL

This extended buffer defines additional encoding controls for reference list. See the *mfxExtAVCRefListCtrl* struc-

ture for details. The application can attach this buffer to the *mfxVideoParam* structure for encoding & decoding initialization, or the *mfxEncodeCtrl* structure for per-frame encoding configuration.

enumerator **MFX_EXTBUFF_VPP_FRAME_RATE_CONVERSION**

This extended buffer defines control parameters for the VPP frame rate conversion algorithm. See the *mfx-ExtVPPFrameRateConversion* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for video processing initialization.

enumerator **MFX_EXTBUFF_PICTURE_TIMING_SEI**

This extended buffer configures the H.264 picture timing SEI message. See the *mfxExtPictureTimingSEI* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for encoding initialization, or the *mfxEncodeCtrl* structure for per-frame encoding configuration.

enumerator **MFX_EXTBUFF_AVC_TEMPORAL_LAYERS**

This extended buffer configures the structure of temporal layers inside the encoded H.264 bitstream. See the *mfxExtAvcTemporalLayers* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for encoding initialization.

enumerator **MFX_EXTBUFF_CODING_OPTION2**

This extended buffer defines additional encoding controls. See the *mfxExtCodingOption2* structure for details. The application can attach this buffer to the structure for encoding initialization.

enumerator **MFX_EXTBUFF_VPP_IMAGE_STABILIZATION**

This extended buffer defines control parameters for the VPP image stabilization filter algorithm. See the *mfx-ExtVPPImageStab* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for video processing initialization.

enumerator **MFX_EXTBUFF_ENCODER_CAPABILITY**

This extended buffer is used to retrieve encoder capability. See the *mfxExtEncoderCapability* structure for details. The application can attach this buffer to the *mfxVideoParam* structure before calling `MFXVideoENCODE_Query` function.

enumerator **MFX_EXTBUFF_ENCODER_RESET_OPTION**

This extended buffer is used to control encoder reset behavior and also to query possible encoder reset outcome. See the *mfxExtEncoderResetOption* structure for details. The application can attach this buffer to the *mfxVideoParam* structure before calling `MFXVideoENCODE_Query` or `MFXVideoENCODE_Reset` functions.

enumerator **MFX_EXTBUFF_ENCODED_FRAME_INFO**

This extended buffer is used by the encoder to report additional information about encoded picture. See the *mfxExtAVCEncodedFrameInfo* structure for details. The application can attach this buffer to the *mfxBistream* structure before calling `MFXVideoENCODE_EncodeFrameAsync` function.

enumerator **MFX_EXTBUFF_VPP_COMPOSITE**

This extended buffer is used to control composition of several input surfaces in the one output. In this mode, the VPP skips any other filters. The VPP returns error if any mandatory filter is specified and filter skipped warning for optional filter. The only supported filters are deinterlacing and interlaced scaling.

enumerator **MFX_EXTBUFF_VPP_VIDEO_SIGNAL_INFO**

This extended buffer is used to control transfer matrix and nominal range of YUV frames. The application should provide it during initialization.

enumerator **MFX_EXTBUFF_ENCODER_ROI**

This extended buffer is used by the application to specify different Region Of Interests during encoding. The application should provide it at initialization or at runtime.

enumerator **MFx_EXTBUFF_VPP_DEINTERLACING**

This extended buffer is used by the application to specify different deinterlacing algorithms.

enumerator **MFx_EXTBUFF_AVC_REFLISTS**

This extended buffer specifies reference lists for the encoder.

enumerator **MFx_EXTBUFF_DEC_VIDEO_PROCESSING**

See the *mfExtDecVideoProcessing* structure for details.

enumerator **MFx_EXTBUFF_VPP_FIELD_PROCESSING**

The extended buffer defines control parameters for the VPP field-processing algorithm. See the *mfExtVPP-FieldProcessing* structure for details. The application can attach this buffer to the *mfVideoParam* structure for video processing initialization or to the *mfFrameData* structure during runtime.

enumerator **MFx_EXTBUFF_CODING_OPTION3**

This extended buffer defines additional encoding controls. See the *mfExtCodingOption3* structure for details. The application can attach this buffer to the structure for encoding initialization.

enumerator **MFx_EXTBUFF_CHROMA_LOC_INFO**

This extended buffer defines chroma samples location information. See the *mfExtChromaLocInfo* structure for details. The application can attach this buffer to the *mfVideoParam* structure for encoding initialization.

enumerator **MFx_EXTBUFF_MBQP**

This extended buffer defines per-macroblock QP. See the *mfExtMBQP* structure for details. The application can attach this buffer to the *mfEncodeCtrl* structure for per-frame encoding configuration.

enumerator **MFx_EXTBUFF_MB_FORCE_INTRA**

This extended buffer defines per-macroblock force intra flag. See the *mfExtMBForceIntra* structure for details. The application can attach this buffer to the *mfEncodeCtrl* structure for per-frame encoding configuration.

enumerator **MFx_EXTBUFF_HEVC_TILES**

This extended buffer defines additional encoding controls for HEVC tiles. See the *mfExtHEVCTiles* structure for details. The application can attach this buffer to the *mfVideoParam* structure for encoding initialization.

enumerator **MFx_EXTBUFF_MB_DISABLE_SKIP_MAP**

This extended buffer defines macroblock map for current frame which forces specified macroblocks to be non skip. See the *mfExtMBDisableSkipMap* structure for details. The application can attach this buffer to the *mfEncodeCtrl* structure for per-frame encoding configuration.

enumerator **MFx_EXTBUFF_HEVC_PARAM**

See the *mfExtHEVCParam* structure for details.

enumerator **MFx_EXTBUFF_DECODED_FRAME_INFO**

This extended buffer is used by decoders to report additional information about decoded frame. See the *mf-ExtDecodedFrameInfo* structure for more details.

enumerator **MFx_EXTBUFF_TIME_CODE**

See the *mfExtTimeCode* structure for more details.

enumerator MFX_EXTBUFF_HEVC_REGION

This extended buffer specifies the region to encode. The application can attach this buffer to the *mfxVideoParam* structure during HEVC encoder initialization.

enumerator MFX_EXTBUFF_PRED_WEIGHT_TABLE

See the *mfxExtPredWeightTable* structure for details.

enumerator MFX_EXTBUFF_DIRTY_RECTANGLES

See the *mfxExtDirtyRect* structure for details.

enumerator MFX_EXTBUFF_MOVING_RECTANGLES

See the *mfxExtMoveRect* structure for details.

enumerator MFX_EXTBUFF_CODING_OPTION_VPS

See the *mfxExtCodingOptionVPS* structure for details.

enumerator MFX_EXTBUFF_VPP_ROTATION

See the *mfxExtVPPRotation* structure for details.

enumerator MFX_EXTBUFF_ENCODED_SLICES_INFO

See the *mfxExtEncodedSlicesInfo* structure for details.

enumerator MFX_EXTBUFF_VPP_SCALING

See the *mfxExtVPPScaling* structure for details.

enumerator MFX_EXTBUFF_HEVC_REFLIST_CTRL

This extended buffer defines additional encoding controls for reference list. See the *mfxExtAVCRefListCtrl* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for encoding & decoding initialization, or the *mfxEncodeCtrl* structure for per-frame encoding configuration.

enumerator MFX_EXTBUFF_HEVC_REFLISTS

This extended buffer specifies reference lists for the encoder.

enumerator MFX_EXTBUFF_HEVC_TEMPORAL_LAYERS

This extended buffer configures the structure of temporal layers inside the encoded H.264 bitstream. See the *mfxExtAvcTemporalLayers* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for encoding initialization.

enumerator MFX_EXTBUFF_VPP_MIRRORING

See the *mfxExtVPPMirroring* structure for details.

enumerator MFX_EXTBUFF_MV_OVER_PIC_BOUNDARIES

See the *mfxExtMVOverPicBoundaries* structure for details.

enumerator MFX_EXTBUFF_VPP_COLORFILL

See the *mfxExtVPPColorFill* structure for details.

enumerator MFX_EXTBUFF_DECODE_ERROR_REPORT

This extended buffer is used by decoders to report error information before frames get decoded. See the *mfx-ExtDecodeErrorReport* structure for more details.

enumerator **MFX_EXTBUFF_VPP_COLOR_CONVERSION**

See the *mfExtColorConversion* structure for details.

enumerator **MFX_EXTBUFF_CONTENT_LIGHT_LEVEL_INFO**

This extended buffer configures HDR SEI message. See the *mfExtContentLightLevelInfo* structure for details.

enumerator **MFX_EXTBUFF_MASTERING_DISPLAY_COLOUR_VOLUME**

This extended buffer configures HDR SEI message. See the *mfExtMasteringDisplayColourVolume* structure for details. If color volume changes per frame, the application can attach this buffer to the *mfxFrmaData* structure for video processing.

enumerator **MFX_EXTBUFF_MASTERING_DISPLAY_COLOUR_VOLUME_IN**

This extended buffer configures HDR SEI message. See the *mfExtMasteringDisplayColourVolume* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for the input of video processing if the mastering display color volume changes per sequence. In this case, this buffer should be together with **MFX_EXTBUFF_CONTENT_LIGHT_LEVEL_INFO** to indicate the light level and mastering color volume of the input of video processing. If color Volume changes per frame instead of per sequence, the application can attach **MFX_EXTBUFF_MASTERING_DISPLAY_COLOUR_VOLUME** to *mfxFrmaData* for frame based processing.

enumerator **MFX_EXTBUFF_MASTERING_DISPLAY_COLOUR_VOLUME_OUT**

This extended buffer configures HDR SEI message. See the *mfExtMasteringDisplayColourVolume* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for the output of video processing if the mastering display color volume changes per sequence. If color volume changes per frame instead of per sequence, the application can attach the buffer with **MFX_EXTBUFF_MASTERING_DISPLAY_COLOUR_VOLUME** to *mfxFrmaData* for frame based processing.

enumerator **MFX_EXTBUFF_ENCODED_UNITS_INFO**

See the *mfExtEncodedUnitsInfo* structure for details.

enumerator **MFX_EXTBUFF_VPP_MCTF**

This video processing algorithm identifier is used to enable MCTF via *mfExtVPPDoUse* and together with *mfExtVppMctf*

enumerator **MFX_EXTBUFF_VP9_SEGMENTATION**

Extends *mfxVideoParam* structure with VP9 segmentation parameters. See the *mfExtVP9Segmentation* structure for details.

enumerator **MFX_EXTBUFF_VP9_TEMPORAL_LAYERS**

Extends *mfxVideoParam* structure with parameters for VP9 temporal scalability. See the *mfExtVP9TemporalLayers* structure for details.

enumerator **MFX_EXTBUFF_VP9_PARAM**

Extends *mfxVideoParam* structure with VP9-specific parameters. See the *mfExtVP9Param* structure for details.

enumerator **MFX_EXTBUFF_AVC_ROUNDING_OFFSET**

See the *mfExtAVCRoundingOffset* structure for details.

enumerator **MFX_EXTBUFF_PARTIAL_BITSTREAM_PARAM**

See the *mfExtPartialBitstreamParam* structure for details.

enumerator **MFX_EXTBUFF_BRC**

enumerator MFX_EXTBUFF_VP8_CODING_OPTION

This extended buffer describes VP8 encoder configuration parameters. See the *mfxExtVP8CodingOption* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for encoding initialization.

enumerator MFX_EXTBUFF_JPEG_QT

This extended buffer defines quantization tables for JPEG encoder.

enumerator MFX_EXTBUFF_JPEG_HUFFMAN

This extended buffer defines Huffman tables for JPEG encoder.

enumerator MFX_EXTBUFF_ENCODER_IPCM_AREA

See the *mfxExtEncoderIPCMArea* structure for details.

enumerator MFX_EXTBUFF_INSERT_HEADERS

See the *mfxExtInsertHeaders* structure for details.

enumerator MFX_EXTBUFF_MVC_SEQ_DESC

This extended buffer describes the MVC stream information of view dependencies, view identifiers, and operation points. See the ITU*-T H.264 specification chapter H.7.3.2.1.4 for details.

enumerator MFX_EXTBUFF_MVC_TARGET_VIEWS

This extended buffer defines target views at the decoder output.

enumerator MFX_EXTBUFF_CENC_PARAM

This structure is used to pass decryption status report index for Common Encryption usage model. See the *mfxExtCencParam* structure for more details.

enumerator MFX_EXTBUFF_DEVICE_AFFINITY_MASK

See the *mfxExtDeviceAffinityMask* structure for details.

enumerator MFX_EXTBUFF_CROPS

See the *mfxExtInCrops* structure for details.

enumerator MFX_EXTBUFF_AV1_FILM_GRAIN_PARAM

See the *mfxExtAV1FilmGrainParam* structure for more details.

enumerator MFX_EXTBUFF_AV1_SEGMENTATION

See the *mfxExtAV1Segmentation* structure for more details.

enumerator MFX_EXTBUFF_ALLOCATION_HINTS

See the *mfxExtAllocationHints* structure for more details.

enumerator MFX_EXTBUFF_UNIVERSAL_TEMPORAL_LAYERS

See the *mfxExtTemporalLayers* structure for more details.

enumerator MFX_EXTBUFF_UNIVERSAL_REFLIST_CTRL

This extended buffer defines additional encoding controls for reference list. See the *mfxExtRefListCtrl* structure for details. The application can attach this buffer to the *mfxVideoParam* structure for encoding & decoding initialization, or the *mfxEncodeCtrl* structure for per-frame encoding configuration.

enumerator **MFx_EXTBUFF_ENCODESTATS**

See the `mfxExtEncodeStats` structure for details.

ExtMemBufferType

enumerator **MFx_MEMTYPE_PERSISTENT_MEMORY**

Memory page for persistent use.

ExtMemFrameType

The `ExtMemFrameType` enumerator specifies the memory type of frame. It is a bit-ORed value of one of the following. For information on working with video memory surfaces, see the *Working with Hardware Acceleration section*.

enumerator **MFx_MEMTYPE_DXVA2_DECODER_TARGET**

Frames are in video memory and belong to video decoder render targets.

enumerator **MFx_MEMTYPE_DXVA2_PROCESSOR_TARGET**

Frames are in video memory and belong to video processor render targets.

enumerator **MFx_MEMTYPE_VIDEO_MEMORY_DECODER_TARGET**

Frames are in video memory and belong to video decoder render targets.

enumerator **MFx_MEMTYPE_VIDEO_MEMORY_PROCESSOR_TARGET**

Frames are in video memory and belong to video processor render targets.

enumerator **MFx_MEMTYPE_SYSTEM_MEMORY**

The frames are in system memory.

enumerator **MFx_MEMTYPE_RESERVED1**

enumerator **MFx_MEMTYPE_FROM_ENCODE**

Allocation request comes from an ENCODE function

enumerator **MFx_MEMTYPE_FROM_DECODE**

Allocation request comes from a DECODE function

enumerator **MFx_MEMTYPE_FROM_VPPIN**

Allocation request comes from a VPP function for input frame allocation

enumerator **MFx_MEMTYPE_FROM_VPPOUT**

Allocation request comes from a VPP function for output frame allocation

enumerator **MFx_MEMTYPE_FROM_ENC**

Allocation request comes from an ENC function

enumerator **MFx_MEMTYPE_INTERNAL_FRAME**

Allocation request for internal frames

enumerator **MFx_MEMTYPE_EXTERNAL_FRAME**

Allocation request for I/O frames

enumerator MFX_MEMTYPE_EXPORT_FRAME

Application requests frame handle export to some associated object. For Linux frame handle can be considered to be exported to DRM Prime FD, DRM FLink or DRM FrameBuffer Handle. Specifics of export types and export procedure depends on external frame allocator implementation

enumerator MFX_MEMTYPE_SHARED_RESOURCE

For DX11 allocation use shared resource bind flag.

enumerator MFX_MEMTYPE_VIDEO_MEMORY_ENCODER_TARGET

Frames are in video memory and belong to video encoder render targets.

Frame Data Flags**enumerator MFX_TIMESTAMP_UNKNOWN**

Indicates that time stamp is unknown for this frame/bitstream portion.

enumerator MFX_FRAMEORDER_UNKNOWN

Unused entry or API functions that generate the frame output do not use this frame.

enumerator MFX_FRAMEDATA_TIMESTAMP_UNKNOWN

Indicates the time stamp of this frame is unknown and will be calculated by SDK.

enumerator MFX_FRAMEDATA_ORIGINAL_TIMESTAMP

Indicates the time stamp of this frame is not calculated and is a pass-through of the original time stamp.

FrameType

The FrameType enumerator itemizes frame types. Use bit-ORed values to specify all that apply.

enumerator MFX_FRAMETYPE_UNKNOWN

Frame type is unspecified.

enumerator MFX_FRAMETYPE_I

This frame or the first field is encoded as an I-frame/field.

enumerator MFX_FRAMETYPE_P

This frame or the first field is encoded as an P-frame/field.

enumerator MFX_FRAMETYPE_B

This frame or the first field is encoded as an B-frame/field.

enumerator MFX_FRAMETYPE_S

This frame or the first field is either an SI- or SP-frame/field.

enumerator MFX_FRAMETYPE_REF

This frame or the first field is encoded as a reference.

enumerator MFX_FRAMETYPE_IDR

This frame or the first field is encoded as an IDR.

enumerator **MFx_FRAMETYPE_xI**

The second field is encoded as an I-field.

enumerator **MFx_FRAMETYPE_xP**

The second field is encoded as an P-field.

enumerator **MFx_FRAMETYPE_xB**

The second field is encoded as an S-field.

enumerator **MFx_FRAMETYPE_xS**

The second field is an SI- or SP-field.

enumerator **MFx_FRAMETYPE_xREF**

The second field is encoded as a reference.

enumerator **MFx_FRAMETYPE_xIDR**

The second field is encoded as an IDR.

FrcAlgm

The FrcAlgm enumerator itemizes frame rate conversion algorithms. See description of mfxExtVPPFrameRateConversion structure for more details.

enumerator **MFx_FRCALGM_PRESERVE_TIMESTAMP**

Frame dropping/repetition based frame rate conversion algorithm with preserved original time stamps. Any inserted frames will carry MFx_TIMESTAMP_UNKNOWN.

enumerator **MFx_FRCALGM_DISTRIBUTED_TIMESTAMP**

Frame dropping/repetition based frame rate conversion algorithm with distributed time stamps. The algorithm distributes output time stamps evenly according to the output frame rate.

enumerator **MFx_FRCALGM_FRAME_INTERPOLATION**

Frame rate conversion algorithm based on frame interpolation. This flag may be combined with MFx_FRCALGM_PRESERVE_TIMESTAMP or MFx_FRCALGM_DISTRIBUTED_TIMESTAMP flags.

GeneralConstraintFlags

The GeneralConstraintFlags enumerator uses bit-ORed values to itemize HEVC bitstream indications for specific profiles. Each value indicates for format range extensions profiles. To specify HEVC Main 10 Still Picture profile applications have to set mfxInfoMFX::CodecProfile == MFx_PROFILE_HEVC_MAIN10 and mfxExtHEVCParam::GeneralConstraintFlags == MFx_HEVC_CONSTR_REXT_ONE_PICTURE_ONLY.

enumerator **MFx_HEVC_CONSTR_REXT_MAX_12BIT**

enumerator **MFx_HEVC_CONSTR_REXT_MAX_10BIT**

enumerator **MFx_HEVC_CONSTR_REXT_MAX_8BIT**

enumerator **MFx_HEVC_CONSTR_REXT_MAX_422CHROMA**

enumerator **MFx_HEVC_CONSTR_REXT_MAX_420CHROMA**

enumerator **MFx_HEVC_CONSTR_REXT_MAX_MONOCHROME**

enumerator **MFx_HEVC_CONSTR_REXT_INTRA**

enumerator **MFx_HEVC_CONSTR_REXT_ONE_PICTURE_ONLY**

enumerator **MFx_HEVC_CONSTR_REXT_LOWER_BIT_RATE**

GopOptFlag

The GopOptFlag enumerator itemizes special properties in the GOP (Group of Pictures) sequence.

enumerator **MFx_GOP_CLOSED**

The encoder generates closed GOP if this flag is set. Frames in this GOP do not use frames in previous GOP as reference.

The encoder generates open GOP if this flag is not set. In this GOP frames prior to the first frame of GOP in display order may use frames from previous GOP as reference. Frames subsequent to the first frame of GOP in display order do not use frames from previous GOP as reference.

The AVC encoder ignores this flag if `IdrInterval` in *mfxfInfoMFX* structure is set to 0, i.e. if every GOP starts from IDR frame. In this case, GOP is encoded as closed.

This flag does not affect long-term reference frames.

enumerator **MFx_GOP_STRICT**

The encoder must strictly follow the given GOP structure as defined by parameter `GopPicSize`, `GopRefDist` etc in the *mfxfVideoParam* structure. Otherwise, the encoder can adapt the GOP structure for better efficiency, whose range is constrained by parameter `GopPicSize` and `GopRefDist` etc. See also description of `AdaptiveI` and `AdaptiveB` fields in the *mfxfExtCodingOption2* structure.

GPUCopy

enumerator **MFx_GPUCOPY_DEFAULT**

Use default mode for the legacy Intel(r) Media SDK implementation.

enumerator **MFx_GPUCOPY_ON**

The hint to enable GPU accelerated copying when it is supported by the library. If the library doesn't support GPU accelerated copy the operation will be made by CPU.

enumerator **MFx_GPUCOPY_OFF**

Disable GPU accelerated copying.

HEVC Profiles

enumerator **MFx_PROFILE_HEVC_MAIN**

enumerator **MFx_PROFILE_HEVC_MAIN10**

enumerator **MFx_PROFILE_HEVC_MAINSP**

enumerator **MFx_PROFILE_HEVC_REXT**

enumerator **MFx_PROFILE_HEVC_SCC**

HEVC Tiers

enumerator **MFX_TIER_HEVC_MAIN**

enumerator **MFX_TIER_HEVC_HIGH**

HEVCRegionEncoding

The HEVCRegionEncoding enumerator itemizes HEVC region's encoding.

enumerator **MFX_HEVC_REGION_ENCODING_ON**

enumerator **MFX_HEVC_REGION_ENCODING_OFF**

HEVCRegionType

The HEVCRegionType enumerator itemizes type of HEVC region.

enumerator **MFX_HEVC_REGION_SLICE**

Slice type.

ImageStabMode

The ImageStabMode enumerator itemizes image stabilization modes. See description of `mfExtVPPIImageStab` structure for more details.

enumerator **MFX_IMAGESTAB_MODE_UPSCALE**

Upscale mode.

enumerator **MFX_IMAGESTAB_MODE_BOXING**

Boxing mode.

InsertHDRPayload

The InsertHDRPayload enumerator itemizes HDR payloads insertion rules.

enumerator **MFX_PAYLOAD_OFF**

Do not insert payload when encoding; Clip does not have valid HDE SEI when decoding.

enumerator **MFX_PAYLOAD_IDR**

Insert payload on IDR frames when encoding; Clip has valid HDE SEI when decoding.

InterpolationMode

The InterpolationMode enumerator specifies type of interpolation method used by VPP scaling filter.

enumerator **MFx_INTERPOLATION_DEFAULT**

Default interpolation mode for scaling. Library selects the most appropriate scaling method.

enumerator **MFx_INTERPOLATION_NEAREST_NEIGHBOR**

Nearest neighbor interpolation method.

enumerator **MFx_INTERPOLATION_BILINEAR**

Bilinear interpolation method.

enumerator **MFx_INTERPOLATION_ADVANCED**

Advanced interpolation method is defined by each implementation and usually gives best quality.

Data Type

enum **mfxDataType**

The mfxDataType enumerates data type for mfxDataType.

Values:

enumerator **MFx_DATA_TYPE_UNSET**

Undefined type.

enumerator **MFx_DATA_TYPE_U8**

8-bit unsigned integer.

enumerator **MFx_DATA_TYPE_I8**

8-bit signed integer.

enumerator **MFx_DATA_TYPE_U16**

16-bit unsigned integer.

enumerator **MFx_DATA_TYPE_I16**

16-bit signed integer.

enumerator **MFx_DATA_TYPE_U32**

32-bit unsigned integer.

enumerator **MFx_DATA_TYPE_I32**

32-bit signed integer.

enumerator **MFx_DATA_TYPE_U64**

64-bit unsigned integer.

enumerator **MFx_DATA_TYPE_I64**

64-bit signed integer.

enumerator **MFx_DATA_TYPE_F32**
32-bit single precision floating point.

enumerator **MFx_DATA_TYPE_F64**
64-bit double precision floating point.

enumerator **MFx_DATA_TYPE_PTR**
Generic type pointer.

enumerator **MFx_DATA_TYPE_FP16**
16-bit half precision floating point.

3DLutChannelMapping

enum **mfx3DLutChannelMapping**

The mfx3DLutChannelMapping enumerator specifies the channel mapping of 3DLUT.

Values:

enumerator **MFx_3DLUT_CHANNEL_MAPPING_DEFAULT**
Default 3DLUT channel mapping. The library selects the most appropriate 3DLUT channel mapping.

enumerator **MFx_3DLUT_CHANNEL_MAPPING_RGB_RGB**
3DLUT RGB channels map to RGB channels.

enumerator **MFx_3DLUT_CHANNEL_MAPPING_YUV_RGB**
3DLUT YUV channels map to RGB channels.

enumerator **MFx_3DLUT_CHANNEL_MAPPING_VUY_RGB**
3DLUT VUY channels map to RGB channels.

3DLutMemoryLayout

enum **mfx3DLutMemoryLayout**

The mfx3DLutMemoryLayout enumerator specifies the memory layout of 3DLUT.

Values:

enumerator **MFx_3DLUT_MEMORY_LAYOUT_DEFAULT**
Default 3DLUT memory layout. The library selects the most appropriate 3DLUT memory layout.

enumerator **MFx_3DLUT_MEMORY_LAYOUT_VENDOR**
The enumeration to separate default above and vendor specific.

enumerator **MFx_3DLUT_MEMORY_LAYOUT_INTEL_17LUT**
Intel specific memory layout. The enumerator indicates the attributes and memory layout of 3DLUT. 3DLUT size is 17(the number of elements per dimension), 4 channels(3 valid channels, 1 channel is reserved), every channel must be 16-bit unsigned integer. 3DLUT contains 17x17x32 entries with holes that are not filled. Take RGB as example, the nodes RxGx17 to RxGx31 are not filled, are “don’t care” bits, and not accessed for the 17x17x17 nodes.

enumerator MFX_3DLUT_MEMORY_LAYOUT_INTEL_33LUT

Intel specific memory layout. The enumerator indicates the attributes and memory layout of 3DLUT. 3DLUT size is 33(the number of elements per dimension), 4 channels(3 valid channels, 1 channel is reserved), every channel must be 16-bit unsigned integer. 3DLUT contains 33x33x64 entries with holes that are not filled. Take RGB as example, the nodes RxGx33 to RxGx63 are not filled, are “don’t care” bits, and not accessed for the 33x33x33 nodes.

enumerator MFX_3DLUT_MEMORY_LAYOUT_INTEL_65LUT

Intel specific memory layout. The enumerator indicates the attributes and memory layout of 3DLUT. 3DLUT size is 65(the number of elements per dimension), 4 channels(3 valid channels, 1 channel is reserved), every channel must be 16-bit unsigned integer. 3DLUT contains 65x65x128 entries with holes that are not filled. Take RGB as example, the nodes RxGx65 to RxGx127 are not filled, are “don’t care” bits, and not accessed for the 65x65x65 nodes.

IntraPredBlockSize/InterPredBlockSize

IntraPredBlockSize/InterPredBlockSize specifies minimum block size of inter-prediction.

enumerator MFX_BLOCKSIZE_UNKNOWN

Unspecified.

enumerator MFX_BLOCKSIZE_MIN_16X16

16x16 minimum block size.

enumerator MFX_BLOCKSIZE_MIN_8X8

8x8 minimum block size. May be 16x16 or 8x8.

enumerator MFX_BLOCKSIZE_MIN_4X4

4x4 minimum block size. May be 16x16, 8x8, or 4x4.

IntraRefreshTypes

The IntraRefreshTypes enumerator itemizes types of intra refresh.

enumerator MFX_REFRESH_NO

Encode without refresh.

enumerator MFX_REFRESH_VERTICAL

Vertical refresh, by column of MBs.

enumerator MFX_REFRESH_HORIZONTAL

Horizontal refresh, by rows of MBs.

enumerator MFX_REFRESH_SLICE

Horizontal refresh by slices without overlapping.

IOPattern

The IOPattern enumerator itemizes memory access patterns for API functions. Use bit-ORed values to specify input and output access patterns.

enumerator **MFX_IOPATTERN_IN_VIDEO_MEMORY**
Input to functions is a video memory surface.

enumerator **MFX_IOPATTERN_IN_SYSTEM_MEMORY**
Input to functions is a linear buffer directly in system memory or in system memory through an external allocator.

enumerator **MFX_IOPATTERN_OUT_VIDEO_MEMORY**
Output to functions is a video memory surface.

enumerator **MFX_IOPATTERN_OUT_SYSTEM_MEMORY**
Output to functions is a linear buffer directly in system memory or in system memory through an external allocator.

JPEGColorFormat

The JPEGColorFormat enumerator itemizes the JPEG color format options.

enumerator **MFX_JPEG_COLORFORMAT_UNKNOWN**

enumerator **MFX_JPEG_COLORFORMAT_YCbCr**
Unknown color format. The decoder tries to determine color format from available in bitstream information. If such information is not present, then MFX_JPEG_COLORFORMAT_YCbCr color format is assumed.

enumerator **MFX_JPEG_COLORFORMAT_RGB**
Bitstream contains Y, Cb and Cr components.

JPEGScanType

The JPEGScanType enumerator itemizes the JPEG scan types.

enumerator **MFX_SCANTYPE_UNKNOWN**
Unknown scan type.

enumerator **MFX_SCANTYPE_INTERLEAVED**
Interleaved scan.

enumerator **MFX_SCANTYPE_NONINTERLEAVED**
Non-interleaved scan.

LongTermIdx

The LongTermIdx specifies long term index of picture control

enumerator **MFx_LONGTERM_IDX_NO_IDX**
Long term index of picture is undefined.

LookAheadDownSampling

The LookAheadDownSampling enumerator is used to control down sampling in look ahead bitrate control mode in AVC encoder.

enumerator **MFx_LOOKAHEAD_DS_UNKNOWN**
Default value, it is up to the encoder what down sampling value to use.

enumerator **MFx_LOOKAHEAD_DS_OFF**
Do not use down sampling, perform estimation on original size frames. This is the slowest setting that produces the best quality.

enumerator **MFx_LOOKAHEAD_DS_2x**
Down sample frames two times before estimation.

enumerator **MFx_LOOKAHEAD_DS_4x**
Down sample frames four times before estimation. This option may significantly degrade quality.

MBQPMode

The MBQPMode enumerator itemizes QP update modes.

enumerator **MFx_MBQP_MODE_QP_VALUE**
QP array contains QP values.

enumerator **MFx_MBQP_MODE_QP_DELTA**
QP array contains deltas for QP.

enumerator **MFx_MBQP_MODE_QP_ADAPTIVE**
QP array contains deltas for QP or absolute QP values.

mfxComponentType

enum **mfxComponentType**
Describes type of workload passed to MFXQueryAdapters.

Values:

enumerator **MFx_COMPONENT_ENCODE**
Encode workload.

enumerator **MFx_COMPONENT_DECODE**
Decode workload.

enumerator **MFX_COMPONENT_VPP**
VPP workload.

mfxHandleType

enum **mfxHandleType**

The mfxHandleType enumerator itemizes system handle types that implementations might use.

Values:

enumerator **MFX_HANDLE_DIRECT3D_DEVICE_MANAGER9**

Pointer to the IDirect3DDeviceManager9 interface. See Working with Microsoft* DirectX* Applications for more details on how to use this handle.

enumerator **MFX_HANDLE_D3D9_DEVICE_MANAGER**

Pointer to the IDirect3DDeviceManager9 interface. See Working with Microsoft* DirectX* Applications for more details on how to use this handle.

enumerator **MFX_HANDLE_RESERVED1**

enumerator **MFX_HANDLE_D3D11_DEVICE**

Pointer to the ID3D11Device interface. See Working with Microsoft* DirectX* Applications for more details on how to use this handle.

enumerator **MFX_HANDLE_VA_DISPLAY**

Pointer to VADisplay interface. See Working with VA-API Applications for more details on how to use this handle.

enumerator **MFX_HANDLE_RESERVED3**

enumerator **MFX_HANDLE_VA_CONFIG_ID**

Pointer to VAConfigID interface. It represents external VA config for Common Encryption usage model.

enumerator **MFX_HANDLE_VA_CONTEXT_ID**

Pointer to VAContextID interface. It represents external VA context for Common Encryption usage model.

enumerator **MFX_HANDLE_CM_DEVICE**

Pointer to CmDevice interface (Intel(r) C for Metal Runtime).

enumerator **MFX_HANDLE_HDDLUNITE_WORKLOADCONTEXT**

Pointer to HddlUnite::WorkloadContext interface.

enumerator **MFX_HANDLE_PXP_CONTEXT**

Pointer to PXP context for protected content support.

mfxIMPL

typedef *mfxI32* **mfxIMPL**

This enumerator itemizes implementation types. The implementation type is a bit OR'ed value of the base type and any decorative flags.

Note: This enumerator is for legacy dispatcher compatibility only. The new dispatcher does not use it.

enumerator **MFX_IMPL_AUTO**

Auto Selection/In or Not Supported/Out.

enumerator **MFX_IMPL_SOFTWARE**

Pure software implementation.

enumerator **MFX_IMPL_HARDWARE**

Hardware accelerated implementation (default device).

enumerator **MFX_IMPL_AUTO_ANY**

Auto selection of any hardware/software implementation.

enumerator **MFX_IMPL_HARDWARE_ANY**

Auto selection of any hardware implementation.

enumerator **MFX_IMPL_HARDWARE2**

Hardware accelerated implementation (2nd device).

enumerator **MFX_IMPL_HARDWARE3**

Hardware accelerated implementation (3rd device).

enumerator **MFX_IMPL_HARDWARE4**

Hardware accelerated implementation (4th device).

enumerator **MFX_IMPL_RUNTIME**

This value cannot be used for session initialization. It may be returned by the MFXQueryIMPL function to show that the session has been initialized in run-time mode.

enumerator **MFX_IMPL_VIA_ANY**

Hardware acceleration can go through any supported OS infrastructure. This is the default value. The default value is used by the legacy Intel(r) Media SDK if none of the MFX_IMPL_VIA_xxx flags are specified by the application.

enumerator **MFX_IMPL_VIA_D3D9**

Hardware acceleration goes through the Microsoft* Direct3D* 9 infrastructure.

enumerator **MFX_IMPL_VIA_D3D11**

Hardware acceleration goes through the Microsoft* Direct3D* 11 infrastructure.

enumerator **MFX_IMPL_VIA_VAAPI**

Hardware acceleration goes through the Linux* VA-API infrastructure.

enumerator **MFX_IMPL_VIA_HDDLUNITE**

Hardware acceleration goes through the HDDL* Unite*.

enumerator **MFX_IMPL_UNSUPPORTED**

One of the MFXQueryIMPL returns.

MFX_IMPL_BASETYPE(x)

The application can use the macro MFX_IMPL_BASETYPE(x) to obtain the base implementation type.

mfxImplCapsDeliveryFormat

enum **mfxImplCapsDeliveryFormat**

Values:

enumerator **MFX_IMPLCAPS_IMPLDESCSTRUCTURE**

Deliver capabilities as *mfxImplDescription* structure.

enumerator **MFX_IMPLCAPS_IMPLEMENTEDFUNCTIONS**

Deliver capabilities as *mfxImplementedFunctions* structure.

enumerator **MFX_IMPLCAPS_IMPLPATH**

Deliver pointer to the null-terminated string with the path to the implementation. String is delivered in a form of buffer of mfxChar type.

enumerator **MFX_IMPLCAPS_DEVICE_ID_EXTENDED**

Deliver extended device ID information as *mfxExtendedDeviceId* structure.

mfxMediaAdapterType

enum **mfxMediaAdapterType**

The mfxMediaAdapterType enumerator itemizes types of graphics adapters.

Values:

enumerator **MFX_MEDIA_UNKNOWN**

Unknown type.

enumerator **MFX_MEDIA_INTEGRATED**

Integrated graphics adapter.

enumerator **MFX_MEDIA_DISCRETE**

Discrete graphics adapter.

mfxMemoryFlags

enum **mfxMemoryFlags**

The mfxMemoryFlags enumerator specifies memory access mode.

Values:

enumerator **MF_X_MAP_READ**

The surface is mapped for reading.

enumerator **MF_X_MAP_WRITE**

The surface is mapped for writing.

enumerator **MF_X_MAP_READ_WRITE**

The surface is mapped for reading and writing.

enumerator **MF_X_MAP_NOWAIT**

The mapping would be done immediately without any implicit synchronizations.

Attention This flag is optional.

MfxNalUnitType

Specifies NAL unit types supported by the HEVC encoder.

enumerator **MF_X_HEVC_NALU_TYPE_UNKNOWN**

The encoder will decide what NAL unit type to use.

enumerator **MF_X_HEVC_NALU_TYPE_TRAIL_N**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

enumerator **MF_X_HEVC_NALU_TYPE_TRAIL_R**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

enumerator **MF_X_HEVC_NALU_TYPE_RADL_N**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

enumerator **MF_X_HEVC_NALU_TYPE_RADL_R**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

enumerator **MF_X_HEVC_NALU_TYPE_RASL_N**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

enumerator **MF_X_HEVC_NALU_TYPE_RASL_R**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

enumerator **MF_X_HEVC_NALU_TYPE_IDR_W_RADL**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

enumerator **MF_X_HEVC_NALU_TYPE_IDR_N_LP**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

enumerator **MFX_HEVC_NALU_TYPE_CRA_NUT**

See Table 7-1 of the ITU-T H.265 specification for the definition of these type.

mfxFriority

enum **mfxFriority**

The mfxPriority enumerator describes the session priority.

Values:

enumerator **MFX_PRIORITY_LOW**

Low priority: the session operation halts when high priority tasks are executing and more than 75% of the CPU is being used for normal priority tasks.

enumerator **MFX_PRIORITY_NORMAL**

Normal priority: the session operation is halted if there are high priority tasks.

enumerator **MFX_PRIORITY_HIGH**

High priority: the session operation blocks other lower priority session operations.

mfxResourceType

enum **mfxResourceType**

Values:

enumerator **MFX_RESOURCE_SYSTEM_SURFACE**

System memory.

enumerator **MFX_RESOURCE_VA_SURFACE_PTR**

Pointer to VA surface index.

enumerator **MFX_RESOURCE_VA_SURFACE**

Pointer to VA surface index.

enumerator **MFX_RESOURCE_VA_BUFFER_PTR**

Pointer to VA buffer index.

enumerator **MFX_RESOURCE_VA_BUFFER**

Pointer to VA buffer index.

enumerator **MFX_RESOURCE_DX9_SURFACE**

IDirect3DSurface9.

enumerator **MFX_RESOURCE_DX11_TEXTURE**

ID3D11Texture2D.

enumerator **MFX_RESOURCE_DX12_RESOURCE**

ID3D12Resource.

enumerator **MFX_RESOURCE_DMA_RESOURCE**
DMA resource.

enumerator **MFX_RESOURCE_HDDLUNITE_REMOTE_MEMORY**
HDDL Unite Remote memory handle.

mfxDiscardMode

enum **mfxDiscardMode**

The **mfxDiscardMode** enumerator describes the decoder skip-mode options.

Values:

enumerator **MFX_SKIPMODE_NOSKIP**

enumerator **MFX_SKIPMODE_MORE**
Do not skip any frames.

enumerator **MFX_SKIPMODE_LESS**
Skip more frames.

mfxDiscardStatus

enum **mfxDiscardStatus**

Itemizes status codes returned by API functions.

Values:

enumerator **MFX_ERR_NONE**
No error.

enumerator **MFX_ERR_UNKNOWN**
Unknown error.

enumerator **MFX_ERR_NULL_PTR**
Null pointer.

enumerator **MFX_ERR_UNSUPPORTED**
Unsupported feature.

enumerator **MFX_ERR_MEMORY_ALLOC**
Failed to allocate memory.

enumerator **MFX_ERR_NOT_ENOUGH_BUFFER**
Insufficient buffer at input/output.

enumerator **MFX_ERR_INVALID_HANDLE**
Invalid handle.

enumerator **MFX_ERR_LOCK_MEMORY**
Failed to lock the memory block.

enumerator **MFx_ERR_NOT_INITIALIZED**
Member function called before initialization.

enumerator **MFx_ERR_NOT_FOUND**
The specified object is not found.

enumerator **MFx_ERR_MORE_DATA**
Expect more data at input.

enumerator **MFx_ERR_MORE_SURFACE**
Expect more surface at output.

enumerator **MFx_ERR_ABORTED**
Operation aborted.

enumerator **MFx_ERR_DEVICE_LOST**
Lose the hardware acceleration device.

enumerator **MFx_ERR_INCOMPATIBLE_VIDEO_PARAM**
Incompatible video parameters.

enumerator **MFx_ERR_INVALID_VIDEO_PARAM**
Invalid video parameters.

enumerator **MFx_ERR_UNDEFINED_BEHAVIOR**
Undefined behavior.

enumerator **MFx_ERR_DEVICE_FAILED**
Device operation failure.

enumerator **MFx_ERR_MORE_BITSTREAM**
Expect more bitstream buffers at output.

enumerator **MFx_ERR_GPU_HANG**
Device operation failure caused by GPU hang.

enumerator **MFx_ERR_REALLOC_SURFACE**
Bigger output surface required.

enumerator **MFx_ERR_RESOURCE_MAPPED**
Write access is already acquired and user requested another write access, or read access with **MFx_MEMORY_NO_WAIT** flag.

enumerator **MFx_ERR_NOT_IMPLEMENTED**
Feature or function not implemented.

enumerator **MFx_WRN_IN_EXECUTION**
The previous asynchronous operation is in execution.

enumerator **MFx_WRN_DEVICE_BUSY**
The hardware acceleration device is busy.

- enumerator **MFx_WRN_VIDEO_PARAM_CHANGED**
The video parameters are changed during decoding.
- enumerator **MFx_WRN_PARTIAL_ACCELERATION**
Software acceleration is used.
- enumerator **MFx_WRN_INCOMPATIBLE_VIDEO_PARAM**
Incompatible video parameters.
- enumerator **MFx_WRN_VALUE_NOT_CHANGED**
The value is saturated based on its valid range.
- enumerator **MFx_WRN_OUT_OF_RANGE**
The value is out of valid range.
- enumerator **MFx_WRN_FILTER_SKIPPED**
One of requested filters has been skipped.
- enumerator **MFx_ERR_NONE_PARTIAL_OUTPUT**
Frame is not ready, but bitstream contains partial output.
- enumerator **MFx_WRN_ALLOC_TIMEOUT_EXPIRED**
Timeout expired for internal frame allocation.
- enumerator **MFx_TASK_DONE**
Task has been completed.
- enumerator **MFx_TASK_WORKING**
There is some more work to do.
- enumerator **MFx_TASK_BUSY**
Task is waiting for resources.
- enumerator **MFx_ERR_MORE_DATA_SUBMIT_TASK**
Return MFx_ERR_MORE_DATA but submit internal asynchronous task.

MirroringType

The MirroringType enumerator itemizes mirroring types.

- enumerator **MFx_MIRRORING_DISABLED**
- enumerator **MFx_MIRRORING_HORIZONTAL**
- enumerator **MFx_MIRRORING_VERTICAL**

DenoiseMode

The mfxDenoiseMode enumerator itemizes denoise modes.

enum **mfxDenoiseMode**

The mfxDenoiseMode enumerator specifies the mode of denoise.

Values:

enumerator **MFX_DENOISE_MODE_DEFAULT**

Default denoise mode. The library selects the most appropriate denoise mode.

enumerator **MFX_DENOISE_MODE_VENDOR**

The enumeration to separate common denoise mode above and vendor specific.

enumerator **MFX_DENOISE_MODE_INTEL_HVS_AUTO_BDRATE**

Indicates auto BD rate improvement in pre-processing before video encoding, ignore Strength.

enumerator **MFX_DENOISE_MODE_INTEL_HVS_AUTO_SUBJECTIVE**

Indicates auto subjective quality improvement in pre-processing before video encoding, ignore Strength.

enumerator **MFX_DENOISE_MODE_INTEL_HVS_AUTO_ADJUST**

Indicates auto adjust subjective quality in post-processing (after decoding) for video playback, ignore Strength.

enumerator **MFX_DENOISE_MODE_INTEL_HVS_PRE_MANUAL**

Indicates manual mode for pre-processing before video encoding, allow to adjust the denoise strength manually.

enumerator **MFX_DENOISE_MODE_INTEL_HVS_POST_MANUAL**

Indicates manual mode for post-processing for video playback, allow to adjust the denoise strength manually.

MPEG-2 Profiles

enumerator **MFX_PROFILE_MPEG2_SIMPLE**

enumerator **MFX_PROFILE_MPEG2_MAIN**

enumerator **MFX_PROFILE_MPEG2_HIGH**

Multi-view Video Coding Extension Profiles

enumerator **MFX_PROFILE_AVC_MULTIVIEW_HIGH**

Multi-view high profile.

enumerator **MFX_PROFILE_AVC_STEREO_HIGH**

Stereo high profile.

MVPrecision

The MVPrecision enumerator specifies the motion estimation precision

enumerator **MFV_MVPRECISION_UNKNOWN**

enumerator **MFV_MVPRECISION_INTEGER**

enumerator **MFV_MVPRECISION_HALFPEL**

enumerator **MFV_MVPRECISION_QUARTERPEL**

NominalRange

The NominalRange enumerator itemizes pixel's value nominal range.

enumerator **MFV_NOMINALRANGE_UNKNOWN**

Range is not defined.

enumerator **MFV_NOMINALRANGE_0_255**

Range is from 0 to 255.

enumerator **MFV_NOMINALRANGE_16_235**

Range is from 16 to 235.

PartialBitstreamOutput

The PartialBitstreamOutput enumerator indicates flags of partial bitstream output type.

enumerator **MFV_PARTIAL_BITSTREAM_NONE**

Do not use partial output

enumerator **MFV_PARTIAL_BITSTREAM_SLICE**

Partial bitstream output will be aligned to slice granularity

enumerator **MFV_PARTIAL_BITSTREAM_BLOCK**

Partial bitstream output will be aligned to user-defined block size granularity

enumerator **MFV_PARTIAL_BITSTREAM_ANY**

Partial bitstream output will be return any coded data available at the end of SyncOperation timeout

PayloadCtrlFlags

The PayloadCtrlFlags enumerator itemizes additional payload properties.

enumerator **MFV_PAYLOAD_CTRL_SUFFIX**

Insert this payload into HEVC Suffix SEI NAL-unit.

PicStruct

The PicStruct enumerator itemizes picture structure. Use bit-OR'ed values to specify the desired picture type.

enumerator **MF_X_PICSTRUCT_UNKNOWN**

Unspecified or mixed progressive/interlaced/field pictures.

enumerator **MF_X_PICSTRUCT_PROGRESSIVE**

Progressive picture.

enumerator **MF_X_PICSTRUCT_FIELD_TFF**

Top field in first interlaced picture.

enumerator **MF_X_PICSTRUCT_FIELD_BFF**

Bottom field in first interlaced picture.

enumerator **MF_X_PICSTRUCT_FIELD_REPEATED**

First field repeated: pic_struct=5 or 6 in H.264.

enumerator **MF_X_PICSTRUCT_FRAME_DOUBLING**

Double the frame for display: pic_struct=7 in H.264.

enumerator **MF_X_PICSTRUCT_FRAME_TRIPLING**

Triple the frame for display: pic_struct=8 in H.264.

enumerator **MF_X_PICSTRUCT_FIELD_SINGLE**

Single field in a picture.

enumerator **MF_X_PICSTRUCT_FIELD_TOP**

Top field in a picture: pic_struct = 1 in H.265.

enumerator **MF_X_PICSTRUCT_FIELD_BOTTOM**

Bottom field in a picture: pic_struct = 2 in H.265.

enumerator **MF_X_PICSTRUCT_FIELD_PAIRED_PREV**

Paired with previous field: pic_struct = 9 or 10 in H.265.

enumerator **MF_X_PICSTRUCT_FIELD_PAIRED_NEXT**

Paired with next field: pic_struct = 11 or 12 in H.265

PicType

The PicType enumerator itemizes picture type.

enumerator **MF_X_PICTYPE_UNKNOWN**

Picture type is unknown.

enumerator **MF_X_PICTYPE_FRAME**

Picture is a frame.

enumerator **MF_X_PICTYPE_TOPFIELD**
Picture is a top field.

enumerator **MF_X_PICTYPE_BOTTOMFIELD**
Picture is a bottom field.

PlatformCodeName

enumerator **MF_X_PLATFORM_UNKNOWN**
Unknown platform.

enumerator **MF_X_PLATFORM_SANDYBRIDGE**
Intel(r) microarchitecture code name Sandy Bridge.

enumerator **MF_X_PLATFORM_IVYBRIDGE**
Intel(r) microarchitecture code name Ivy Bridge.

enumerator **MF_X_PLATFORM_HASWELL**
Code name Haswell.

enumerator **MF_X_PLATFORM_BAYTRAIL**
Code name Bay Trail.

enumerator **MF_X_PLATFORM_BROADWELL**
Intel(r) microarchitecture code name Broadwell.

enumerator **MF_X_PLATFORM_CHERRYTRAIL**
Code name Cherry Trail.

enumerator **MF_X_PLATFORM_SKYLAKE**
Intel(r) microarchitecture code name Skylake.

enumerator **MF_X_PLATFORM_APOLLOLAKE**
Code name Apollo Lake.

enumerator **MF_X_PLATFORM_KABYLAKE**
Code name Kaby Lake.

enumerator **MF_X_PLATFORM_GEMINILAKE**
Code name Gemini Lake.

enumerator **MF_X_PLATFORM_COFFEELAKE**
Code name Coffee Lake.

enumerator **MF_X_PLATFORM_CANNONLAKE**
Code name Cannon Lake.

enumerator **MF_X_PLATFORM_ICELAKE**
Code name Ice Lake.

enumerator **MFx_PLATFORM_JASPERLAKE**
Code name Jasper Lake.

enumerator **MFx_PLATFORM_ELKHARTLAKE**
Code name Elkhart Lake.

enumerator **MFx_PLATFORM_TIGERLAKE**
Code name Tiger Lake.

enumerator **MFx_PLATFORM_ROCKETLAKE**
Code name Rocket Lake.

enumerator **MFx_PLATFORM_ALDERLAKE_S**
Code name Alder Lake S.

enumerator **MFx_PLATFORM_ALDERLAKE_P**
Code name Alder Lake P.

enumerator **MFx_PLATFORM_ALDERLAKE_N**
Code name Alder Lake N.

enumerator **MFx_PLATFORM_XEHP_SDV**
Code name XeHP SDV.

enumerator **MFx_PLATFORM_DG2**
Code name DG2.

enumerator **MFx_PLATFORM_ATS_M**
Code name ATS-M, same media functionality as DG2.

enumerator **MFx_PLATFORM_KEEMBAY**
Code name Keem Bay.

PRefType

The PRefType enumerator itemizes models of reference list construction and DPB management when GopRefDist=1.

enumerator **MFx_P_REF_DEFAULT**
Allow encoder to decide.

enumerator **MFx_P_REF_SIMPLE**
Regular sliding window used for DPB removal process.

enumerator **MFx_P_REF_PYRAMID**
Let N be the max reference list's size. Encoder treats each N's frame as a 'strong' reference and the others as 'weak' references. The encoder uses a 'weak' reference only for prediction of the next frame and removes it from DPB immediately after use. 'Strong' references are removed from DPB by a sliding window.

Protected

The Protected enumerator describes the protection schemes.

enumerator **MF_X_PROTECTION_CENC_WV_CLASSIC**

The protection scheme is based on the Widevine* DRM from Google*.

enumerator **MF_X_PROTECTION_CENC_WV_GOOGLE_DASH**

The protection scheme is based on the Widevine* Modular DRM* from Google*.

RateControlMethod

The RateControlMethod enumerator itemizes bitrate control methods.

enumerator **MF_X_RATECONTROL_CBR**

Use the constant bitrate control algorithm.

enumerator **MF_X_RATECONTROL_VBR**

Use the variable bitrate control algorithm.

enumerator **MF_X_RATECONTROL_CQP**

Use the constant quantization parameter algorithm.

enumerator **MF_X_RATECONTROL_AVBR**

Use the average variable bitrate control algorithm.

enumerator **MF_X_RATECONTROL_LA**

Use the VBR algorithm with look ahead. It is a special bitrate control mode in the AVC encoder that has been designed to improve encoding quality. It works by performing extensive analysis of several dozen frames before the actual encoding and as a side effect significantly increases encoding delay and memory consumption.

The only available rate control parameter in this mode is *mf_xInfoMFX::TargetKbps*. Two other parameters, MaxKbps and InitialDelayInKB, are ignored. To control LA depth the application can use *mf_xExtCodingOption2::LookAheadDepth* parameter.

This method is not HRD compliant.

enumerator **MF_X_RATECONTROL_ICQ**

Use the Intelligent Constant Quality algorithm. This algorithm improves subjective video quality of encoded stream. Depending on content, it may or may not decrease objective video quality. Only one control parameter is used - quality factor, specified by *mf_xInfoMFX::ICQQuality*.

enumerator **MF_X_RATECONTROL_VCM**

Use the Video Conferencing Mode algorithm. This algorithm is similar to the VBR and uses the same set of parameters *mf_xInfoMFX::InitialDelayInKB*, *TargetKbps* and *MaxKbps*. It is tuned for IPPP GOP pattern and streams with strong temporal correlation between frames. It produces better objective and subjective video quality in these conditions than other bitrate control algorithms. It does not support interlaced content, B-frames and produced stream is not HRD compliant.

enumerator **MF_X_RATECONTROL_LA_ICQ**

Use Intelligent Constant Quality algorithm with look ahead. Quality factor is specified by *mf_xInfoMFX::ICQQuality*. To control LA depth the application can use *mf_xExtCodingOption2::LookAheadDepth* parameter.

This method is not HRD compliant.

enumerator **MF_X_RATECONTROL_LA_HRD**

MF_X_RATECONTROL_LA_EXT has been removed

Use HRD compliant look ahead rate control algorithm.

enumerator **MF_X_RATECONTROL_QVBR**

Use the variable bitrate control algorithm with constant quality. This algorithm trying to achieve the target subjective quality with the minimum number of bits, while the bitrate constraint and HRD compliance are satisfied. It uses the same set of parameters as VBR and quality factor specified by *mfExtCodingOption3::QVBRQuality*.

ROI mode

The ROI mode enumerator itemizes QP adjustment mode for ROIs.

enumerator **MF_X_ROI_MODE_PRIORITY**

Priority mode.

enumerator **MF_X_ROI_MODE_QP_DELTA**

QP mode

enumerator **MF_X_ROI_MODE_QP_VALUE**

Absolute QP

Rotation

The Rotation enumerator itemizes the JPEG rotation options.

enumerator **MF_X_ROTATION_0**

No rotation.

enumerator **MF_X_ROTATION_90**

90 degree rotation.

enumerator **MF_X_ROTATION_180**

180 degree rotation.

enumerator **MF_X_ROTATION_270**

270 degree rotation.

SampleAdaptiveOffset

The SampleAdaptiveOffset enumerator uses bit-ORed values to itemize corresponding HEVC encoding feature.

enumerator **MF_X_SAO_UNKNOWN**

Use default value for platform/TargetUsage.

enumerator **MF_X_SAO_DISABLE**

Disable SAO. If set during Init leads to SPS `sample_adaptive_offset_enabled_flag = 0`. If set during Runtime, leads to `slice_sao_luma_flag = 0` and `slice_sao_chroma_flag = 0` for current frame.

enumerator **MFx_SAO_ENABLE_LUMA**
 Enable SAO for luma (slice_sao_luma_flag = 1).

enumerator **MFx_SAO_ENABLE_CHROMA**
 Enable SAO for chroma (slice_sao_chroma_flag = 1).

ScalingMode

The ScalingMode enumerator itemizes variants of scaling filter implementation.

enumerator **MFx_SCALING_MODE_DEFAULT**
 Default scaling mode. The library selects the most appropriate scaling method.

enumerator **MFx_SCALING_MODE_LOWPOWER**
 Low power scaling mode which is applicable for library implementations. The exact scaling algorithm is defined by the library.

enumerator **MFx_SCALING_MODE_QUALITY**
 The best quality scaling mode.

enumerator **MFx_SCALING_MODE_VENDOR**
 The enumeration to separate common scaling controls above and vendor specific.

enumerator **MFx_SCALING_MODE_INTEL_GEN_COMPUTE**

enumerator **MFx_SCALING_MODE_INTEL_GEN_VDBOX**
 The mode to run scaling operation on Execution Units (EUs).

enumerator **MFx_SCALING_MODE_INTEL_GEN_VEBOX**
 The special optimization mode where scaling operation running on SFC (Scaler & Format Converter) is coupled with VDBOX (also known as Multi-Format Codec fixed-function engine). This mode is applicable for DECODE_VPP domain functions.

ScenarioInfo

The ScenarioInfo enumerator itemizes scenarios for the encoding session.

enumerator **MFx_SCENARIO_UNKNOWN**

enumerator **MFx_SCENARIO_DISPLAY_REMOTING**

enumerator **MFx_SCENARIO_VIDEO_CONFERENCE**

enumerator **MFx_SCENARIO_ARCHIVE**

enumerator **MFx_SCENARIO_LIVE_STREAMING**

enumerator **MFx_SCENARIO_CAMERA_CAPTURE**

enumerator **MFx_SCENARIO_VIDEO_SURVEILLANCE**

enumerator **MFx_SCENARIO_GAME_STREAMING**

enumerator **MFx_SCENARIO_REMOTE_GAMING**

SegmentFeature

The SegmentFeature enumerator indicates features enabled for the segment. These values are used with the `mfxVP9SegmentParam::FeatureEnabled` parameter.

enumerator **MF_X_VP9_SEGMENT_FEATURE_QINDEX**

Quantization index delta.

enumerator **MF_X_VP9_SEGMENT_FEATURE_LOOP_FILTER**

Loop filter level delta.

enumerator **MF_X_VP9_SEGMENT_FEATURE_REFERENCE**

Reference frame.

enumerator **MF_X_VP9_SEGMENT_FEATURE_SKIP**

Skip.

SegmentIdBlockSize

The SegmentIdBlockSize enumerator indicates the block size represented by each `segment_id` in segmentation map. These values are used with the `mfxExtVP9Segmentation::SegmentIdBlockSize` parameter.

enumerator **MF_X_VP9_SEGMENT_ID_BLOCK_SIZE_UNKNOWN**

Unspecified block size.

enumerator **MF_X_VP9_SEGMENT_ID_BLOCK_SIZE_8x8**

8x8 block size.

enumerator **MF_X_VP9_SEGMENT_ID_BLOCK_SIZE_16x16**

16x16 block size.

enumerator **MF_X_VP9_SEGMENT_ID_BLOCK_SIZE_32x32**

32x32 block size.

enumerator **MF_X_VP9_SEGMENT_ID_BLOCK_SIZE_64x64**

64x64 block size.

SkipFrame

The SkipFrame enumerator is used to define usage of `mfxEncodeCtrl::SkipFrame` parameter.

enumerator **MF_X_SKIPFRAME_NO_SKIP**

Frame skipping is disabled, *mfxEncodeCtrl::SkipFrame* is ignored.

enumerator **MF_X_SKIPFRAME_INSERT_DUMMY**

Skipping is allowed, when *mfxEncodeCtrl::SkipFrame* is set encoder inserts into bitstream frame where all macroblocks are encoded as skipped. Only non-reference P- and B-frames can be skipped. If `GopRefDist = 1` and *mfxEncodeCtrl::SkipFrame* is set for reference P-frame, it will be encoded as non-reference.

enumerator **MFX_SKIPFRAME_INSERT_NOTHING**

Similar to **MFX_SKIPFRAME_INSERT_DUMMY**, but when *mfxEncodeCtrl::SkipFrame* is set encoder inserts nothing into bitstream.

enumerator **MFX_SKIPFRAME_BRC_ONLY**

mfxEncodeCtrl::SkipFrame indicates number of missed frames before the current frame. Affects only BRC, current frame will be encoded as usual.

TargetUsage

The **TargetUsage** enumerator itemizes a range of numbers from **MFX_TARGETUSAGE_1**, best quality, to **MFX_TARGETUSAGE_7**, best speed. It indicates trade-offs between quality and speed. The application can use any number in the range. The actual number of supported target usages depends on implementation. If the specified target usage is not supported, the encoder will use the closest supported value.

enumerator **MFX_TARGETUSAGE_1**

Best quality

enumerator **MFX_TARGETUSAGE_2**

enumerator **MFX_TARGETUSAGE_3**

enumerator **MFX_TARGETUSAGE_4**

Balanced quality and speed.

enumerator **MFX_TARGETUSAGE_5**

enumerator **MFX_TARGETUSAGE_6**

enumerator **MFX_TARGETUSAGE_7**

Best speed

enumerator **MFX_TARGETUSAGE_UNKNOWN**

Unspecified target usage.

enumerator **MFX_TARGETUSAGE_BEST_QUALITY**

Best quality.

enumerator **MFX_TARGETUSAGE_BALANCED**

Balanced quality and speed.

enumerator **MFX_TARGETUSAGE_BEST_SPEED**

Best speed.

TelecinePattern

The TelecinePattern enumerator itemizes telecine patterns.

enumerator **MFX_TELECINE_PATTERN_32**
3:2 telecine.

enumerator **MFX_TELECINE_PATTERN_2332**
2:3:3:2 telecine.

enumerator **MFX_TELECINE_PATTERN_FRAME_REPEAT**
One frame repeat telecine.

enumerator **MFX_TELECINE_PATTERN_41**
4:1 telecine.

enumerator **MFX_TELECINE_POSITION_PROVIDED**
User must provide position inside a sequence of 5 frames where the artifacts start.

TimeStampCalc

The TimeStampCalc enumerator itemizes time-stamp calculation methods.

enumerator **MFX_TIMESTAMP_CALC_UNKNOWN**
The time stamp calculation is based on the input frame rate if time stamp is not explicitly specified.

enumerator **MFX_TIMESTAMP_CALC_TELECINE**
Adjust time stamp to 29.97fps on 24fps progressively encoded sequences if telecine attributes are available in the bitstream and time stamp is not explicitly specified. The input frame rate must be specified.

TransferMatrix

The TransferMatrix enumerator itemizes color transfer matrices.

enumerator **MFX_TRANSFERMATRIX_UNKNOWN**
Transfer matrix is not specified

enumerator **MFX_TRANSFERMATRIX_BT709**
Transfer matrix from ITU-R BT.709 standard.

enumerator **MFX_TRANSFERMATRIX_BT601**
Transfer matrix from ITU-R BT.601 standard.

TrellisControl

The TrellisControl enumerator is used to control trellis quantization in AVC encoder. The application can turn it on or off for any combination of I, P, and B frames by combining different enumerator values. For example, `MFX_TRELLIS_I | MFX_TRELLIS_B` turns it on for I and B frames.

enumerator **MFX_TRELLIS_UNKNOWN**

Default value, it is up to the encoder to turn trellis quantization on or off.

enumerator **MFX_TRELLIS_OFF**

Turn trellis quantization off for all frame types.

enumerator **MFX_TRELLIS_I**

Turn trellis quantization on for I-frames.

enumerator **MFX_TRELLIS_P**

Turn trellis quantization on for P-frames.

enumerator **MFX_TRELLIS_B**

Turn trellis quantization on for B-frames.

VP9ReferenceFrame

The VP9ReferenceFrame enumerator itemizes reference frame type by the `mfxVP9SegmentParam::ReferenceFrame` parameter.

enumerator **MFX_VP9_REF_INTRA**

Intra.

enumerator **MFX_VP9_REF_LAST**

Last.

enumerator **MFX_VP9_REF_GOLDEN**

Golden.

enumerator **MFX_VP9_REF_ALTREF**

Alternative reference.

VPPFieldProcessingMode

The VPPFieldProcessingMode enumerator is used to control VPP field processing algorithm.

enumerator **MFX_VPP_COPY_FRAME**

Copy the whole frame.

enumerator **MFX_VPP_COPY_FIELD**

Copy only one field.

enumerator **MFX_VPP_SWAP_FIELDS**

Swap top and bottom fields.

WeightedPred

The WeightedPred enumerator itemizes weighted prediction modes.

enumerator **MF_X_WEIGHTED_PRED_UNKNOWN**
Allow encoder to decide.

enumerator **MF_X_WEIGHTED_PRED_DEFAULT**
Use default weighted prediction.

enumerator **MF_X_WEIGHTED_PRED_EXPLICIT**
Use explicit weighted prediction.

enumerator **MF_X_WEIGHTED_PRED_IMPLICIT**
Use implicit weighted prediction (for B-frames only).

FilmGrainFlags

The FilmGrainFlags enumerator itemizes flags in AV1 film grain parameters.

enumerator **MF_X_FILM_GRAIN_NO**
Film grain isn't added to this frame.

enumerator **MF_X_FILM_GRAIN_APPLY**
Film grain is added to this frame.

enumerator **MF_X_FILM_GRAIN_UPDATE**
New set of film grain parameters is sent for this frame.

enumerator **MF_X_FILM_GRAIN_CHROMA_SCALING_FROM_LUMA**
Chroma scaling is inferred from luma scaling.

enumerator **MF_X_FILM_GRAIN_OVERLAP**
Overlap between film grain blocks is applied.

enumerator **MF_X_FILM_GRAIN_CLIP_TO_RESTRICTED_RANGE**
Clipping to the restricted (studio) range is applied after adding the film grain.

mfxHyperMode

enum **mfxHyperMode**
The mfxHyperMode enumerator describes HyperMode implementation behavior.

Values:

enumerator **MF_X_HYPERMODE_OFF**
Don't use HyperMode implementation.

enumerator **MF_X_HYPERMODE_ON**
Enable HyperMode implementation and return error if some issue on initialization.

enumerator **MFx_HYPERMODE_ADAPTIVE**

Enable HyperMode implementation and switch to single fallback if some issue on initialization.

mfXPoolAllocationPolicy

enum **mfXPoolAllocationPolicy**

Specifies the surface pool allocation policies.

Values:

enumerator **MFx_ALLOCATION_OPTIMAL**

Recommends to limit max pool size by sum of requested surfaces asked by components.

enumerator **MFx_ALLOCATION_UNLIMITED**

Dynamic allocation with no limit.

enumerator **MFx_ALLOCATION_LIMITED**

Max pool size is limited by NumberToPreAllocate + DeltaToAllocateOnTheFly.

mfXVPPPoolType

enum **mfXVPPPoolType**

Values:

enumerator **MFx_VPP_POOL_IN**

Input pool.

enumerator **MFx_VPP_POOL_OUT**

Output pool.

mfXAV1SegmentIdBlockSize

The mfXAV1SegmentIdBlockSize enumerator indicates the block size represented by each segment_id in segmentation map.

enum **mfXAV1SegmentIdBlockSize**

The AV1 SegmentIdBlockSize enumerator indicates the block size represented by each segment_id in segmentation map. These values are used with the *mfXExtAV1Segmentation::SegmentIdBlockSize* parameter.

Values:

enumerator **MFx_AV1_SEGMENT_ID_BLOCK_SIZE_UNSPECIFIED**

Unspecified block size.

enumerator **MFx_AV1_SEGMENT_ID_BLOCK_SIZE_4x4**

block size 4x4

enumerator **MFx_AV1_SEGMENT_ID_BLOCK_SIZE_8x8**

block size 8x8

enumerator **MFx_AV1_SEGMENT_ID_BLOCK_SIZE_16x16**
block size 16x16

enumerator **MFx_AV1_SEGMENT_ID_BLOCK_SIZE_32x32**
block size 32x32

enumerator **MFx_AV1_SEGMENT_ID_BLOCK_SIZE_64x64**
block size 64x64

enumerator **MFx_AV1_SEGMENT_ID_BLOCK_SIZE_128x128**
block size 128x128

AV1SegmentFeature

The AV1SegmentFeature enumerator indicates features enabled for the segment.

enumerator **MFx_AV1_SEGMENT_FEATURE_ALT_QINDEX**
use alternate Quantizer.

enumerator **MFx_AV1_SEGMENT_FEATURE_ALT_LF_Y_VERT**
use alternate loop filter value on y plane vertical.

enumerator **MFx_AV1_SEGMENT_FEATURE_ALT_LF_Y_HORZ**
use alternate loop filter value on y plane horizontal.

enumerator **MFx_AV1_SEGMENT_FEATURE_ALT_LF_U**
use alternate loop filter value on u plane.

enumerator **MFx_AV1_SEGMENT_FEATURE_ALT_LF_V**
use alternate loop filter value on v plane.

enumerator **MFx_AV1_SEGMENT_FEATURE_REFERENCE**
use segment reference frame.

enumerator **MFx_AV1_SEGMENT_FEATURE_SKIP**
use segment (0,0) + skip mode.

enumerator **MFx_AV1_SEGMENT_FEATURE_GLOBALMV**
use global motion vector.

mfxEncodeBlkStatsMemLayout

enum **mfxEncodeBlkStatsMemLayout**
< The enum to specify memory layout for statistics.

Values:

enumerator **MFx_ENCODESTATS_MEMORY_LAYOUT_DEFAULT**
The default memory layout for statistics.

mfxEncodeStatsMode

enum **mfxEncodeStatsMode**

Values:

enumerator **MFX_ENCODESTATS_MODE_DEFAULT**

Encode mode is selected by the implementation.

enumerator **MFX_ENCODESTATS_MODE_ENCODE**

Full encode mode.

EncodeStatsLevel

Flags to specify what statistics will be reported by the implementation.

enumerator **MFX_ENCODESTATS_LEVEL_BLK**

Block level statistics.

enumerator **MFX_ENCODESTATS_LEVEL_FRAME**

Frame level statistics.

10.5.4 Define Reference

API

MFX_DECODERDESCRIPTION_VERSION

MFX_DEVICEDESCRIPTION_VERSION

The current version of *mfxDeviceDescription* structure.

MFX_ENCODERDESCRIPTION_VERSION

MFX_FRAMESURFACE1_VERSION

MFX_FRAMESURFACEINTERFACE_VERSION

MFX_IMPLDESCRIPTION_VERSION

The current version of *mfxImplDescription* structure.

MFX_LEGACY_VERSION

The corresponding version of the Intel(r) Media SDK legacy API that is used as a basis for the current API.

MFX_STRUCT_VERSION(MAJOR, MINOR)

MFX_VARIANT_VERSION

MFX_VERSION

MFX_VERSION_MAJOR

MFX_VERSION_MINOR

MFX_VPPDESCRIPTION_VERSION

MFx_SURFACEARRAY_VERSION

10.5.5 Type Reference

- *Basic Types*
- *Typedefs*

Basic Types

typedef char **mfChar**
UTF-8 byte.

typedef float **mfF32**
Single-precision floating point, 32 bit type.

typedef double **mfF64**
Double-precision floating point, 64 bit type.

typedef void ***mfHDL**
Handle type.

typedef char **mfI8**
Signed integer, 8 bit type.

typedef short **mfI16**
Signed integer, 16 bit type.

typedef int **mfI32**
Signed integer, 32 bit type.

typedef long long **mfI64**
Signed integer, 64 bit type.

typedef int **mfL32**
Signed integer, 32 bit type.

typedef *mfHDL* **mfMemId**
Memory ID type.

typedef void ***mfThreadTask**
Thread task type.

typedef unsigned char **mfU8**
Unsigned integer, 8 bit type.

typedef unsigned short **mfU16**
Unsigned integer, 16 bit type.

typedef unsigned int **mfXU32**
 Unsigned integer, 32 bit type.

typedef unsigned long long **mfXU64**
 Unsigned integer, 64 bit type.

typedef unsigned int **mfXUL32**
 Unsigned integer, 32 bit type.

Typedefs

typedef struct _mfXConfig ***mfXConfig**
 Config handle.

typedef struct _mfXLoader ***mfXLoader**
 Loader handle.

typedef struct _mfXSession ***mfXSession**
 Session handle.

typedef struct _mfXSyncPoint ***mfXSyncPoint**
 Synchronization point object handle.

typedef *mfXExtAVCRefListCtrl* **mfXExtRefListCtrl**

10.5.6 Dispatcher API

Use the Dispatcher API to load and execute the appropriate library implementation and get capabilities for the implementations available on the platform.

Dispatcher API Function Reference

API

- *MFXCreateConfig*
- *MFXCreateSession*
- *MFXDispReleaseImplDescription*
- *MFXEnumImplementations*
- *MFXLoad*
- *MFXSetConfigFilterProperty*
- *MFXUnload*

MFxCreateConfig

mfxConfig **MFxCreateConfig**(*mfxLoader* loader)

Creates dispatcher configuration.

Creates the dispatcher internal configuration, which is used to filter out available implementations. This configuration is used to walk through selected implementations to gather more details and select the appropriate implementation to load. The loader object remembers all created *mfxConfig* objects and destroys them during the *mfxUnload* function call.

Multiple configurations per single *mfxLoader* object are possible.

Usage example:

```
mfxLoader loader = MFxLoad();
mfxConfig cfg = MFxCreateConfig(loader);
MFxCreateSession(loader, 0, &session);
```

Since This function is available since API version 2.0.

Parameters **loader** – [in] Loader handle.

Returns Config handle or NULL pointer is failed.

MFxCreateSession

mfxStatus **MFxCreateSession**(*mfxLoader* loader, *mfxU32* i, *mfxSession* *session)

Loads and initializes the implementation.

```
mfxLoader loader = MFxLoad();
int i=0;
while(1) {
    mfxImplDescription *idesc;
    MFxEnumImplementations(loader, i, MFx_IMPLCAPS_IMPLDESCSTRUCTURE, (mfxHDL*)&
↪idesc);
    if(is_good(idesc)) {
        MFxCreateSession(loader, i, &session);
        // ...
        MFxDispReleaseImplDescription(loader, idesc);
    }
    else
    {
        MFxDispReleaseImplDescription(loader, idesc);
        break;
    }
}
```

Since This function is available since API version 2.0.

Parameters

- **loader** – [in] Loader handle.
- **i** – [in] Index of the implementation.

- **session** – [out] Pointer to the session handle.

Returns

MFX_ERR_NONE The function completed successfully. The session contains a pointer to the session handle.

MFX_ERR_NULL_PTR If loader is NULL.

MFX_ERR_NULL_PTR If session is NULL.

MFX_ERR_NOT_FOUND Provided index is out of possible range.

MFXDispReleaseImplDescription

mfxStatus **MFXDispReleaseImplDescription**(*mfxLoader* loader, *mfxHDL* hdl)
Destroys handle allocated by the MFXEnumImplementations function.

Since This function is available since API version 2.0.

Parameters

- **loader** – [in] Loader handle.
- **hdl** – [in] Handle to destroy. Can be equal to NULL.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_NULL_PTR If loader is NULL.

MFX_ERR_INVALID_HANDLE Provided hdl handle is not associated with this loader.

MFXEnumImplementations

mfxStatus **MFXEnumImplementations**(*mfxLoader* loader, *mfxU32* i, *mfxImplCapsDeliveryFormat* format, *mfxHDL* *idesc)

Iterates over filtered out implementations to gather their details. This function allocates memory to store *mfxImplDescription* structure instance. Use the MFXDispReleaseImplDescription function to free memory allocated to the *mfxImplDescription* structure.

Since This function is available since API version 2.0.

Parameters

- **loader** – [in] Loader handle.
- **i** – [in] Index of the implementation.
- **format** – [in] Format in which capabilities need to be delivered. See the *mfxImplCapsDeliveryFormat* enumerator for more details.
- **idesc** – [out] Pointer to the *mfxImplDescription* structure.

Returns

MFX_ERR_NONE The function completed successfully. The *idesc* contains valid information.

MFX_ERR_NULL_PTR If loader is NULL.

MFX_ERR_NULL_PTR If *idesc* is NULL.

MFX_ERR_NOT_FOUND Provided index is out of possible range.

MFX_ERR_UNSUPPORTED If requested format is not supported.

MFXLoad

mfxLoader **MFXLoad**(void)

Creates the loader.

Since This function is available since API version 2.0.

Returns Loader Loader handle or NULL if failed.

MFXSetConfigFilterProperty

mfxStatus **MFXSetConfigFilterProperty**(*mfxConfig* config, const *mfxUS* *name, *mfxVariant* value)

Adds additional filter properties (any fields of the *mfxImplDescription* structure) to the configuration of the loader object. One *mfxConfig* properties can hold only single filter property.

Since This function is available since API version 2.0.

Note: Each new call with the same parameter name will overwrite the previously set value. This may invalidate other properties.

Note: Each new call with another parameter name will delete the previous property and create a new property based on new name's value.

Parameters

- **config** – [in] Config handle.
- **name** – [in] Name of the parameter (see *mfxImplDescription* structure and example).
- **value** – [in] Value of the parameter.

Returns

MFX_ERR_NONE The function completed successfully. **MFX_ERR_NULL_PTR** If config is NULL.

MFX_ERR_NULL_PTR If name is NULL.

MFX_ERR_NOT_FOUND If name contains unknown parameter name.

MFX_ERR_UNSUPPORTED If value data type does not equal the parameter with provided name.

MFXUnload

void **MFXUnload**(*mfxLoader* loader)
Destroys the dispatcher.

Since This function is available since API version 2.0.

Parameters **loader** – [in] Loader handle.

Dispatcher API Structure Reference

API

- *mfxDecoderDescription*

mfxDecoderDescription

struct **mfxDecoderDescription**

The *mfxDecoderDescription* structure represents the description of a decoder.

Public Members

mfxStructVersion **Version**
Version of the structure.

mfxU16 **reserved**[7]
Reserved for future use.

mfxU16 **NumCodecs**
Number of supported decoders.

struct *mfxDecoderDescription::decoder* ***Codecs**
Pointer to the array of decoders.

struct **decoder**

This structure represents the decoder description.

Public Members

mfxU32 **CodecID**

Decoder ID in FourCC format.

mfxU16 **reserved**[8]

Reserved for future use.

mfxU16 **MaxcodecLevel**

Maximum supported codec level. See the CodecProfile enumerator for possible values.

mfxU16 **NumProfiles**

Number of supported profiles.

struct *mfxDecoderDescription::decoder::decprofile* ***Profiles**

Pointer to the array of profiles supported by the codec.

struct **decprofile**

This structure represents the codec profile description.

Public Members

mfxU32 **Profile**

Profile ID. See the CodecProfile enumerator for possible values.

mfxU16 **reserved**[7]

Reserved for future use.

mfxU16 **NumMemTypes**

Number of supported memory types.

struct *mfxDecoderDescription::decoder::decprofile::decmemdesc* ***MemDesc**

Pointer to the array of memory types.

struct **decmemdesc**

This structure represents the underlying details of the memory type.

Public Members

mfResourceType **MemHandleType**

Memory handle type.

mfRange32U **Width**

Range of supported image widths.

mfRange32U **Height**

Range of supported image heights.

mfU16 **reserved[7]**

Reserved for future use.

mfU16 **NumColorFormats**

Number of supported output color formats.

mfU32 ***ColorFormats**

Pointer to the array of supported output color formats (in FOURCC).

mfDeviceDescription

struct **mfDeviceDescription**

This structure represents device description.

Public Members

mfStructVersion **Version**

Version of the structure.

mfU16 **reserved[6]**

reserved for future use.

mfU16 **MediaAdapterType**

Graphics adapter type. See the `mfMediaAdapterType` enumerator for a list of possible values.

mfChar **DeviceID[MFX_STRFIELD_LEN]**

Null terminated string with device ID.

mfU16 **NumSubDevices**

Number of available uniform sub-devices. Pure software implementation can report 0.

struct *mfDeviceDescription::subdevices* ***SubDevices**

Pointer to the array of available sub-devices.

struct **subdevices**

This structure represents sub-device description.

Public Members

mfxU32 **Index**

Index of the sub-device, started from 0 and increased by 1.

mfxChar **SubDeviceID**[MFX_STRFIELD_LEN]

Null terminated string with unique sub-device ID, mapped to the system ID.

mfxU32 **reserved**[7]

reserved for future use.

mfxEncoderDescription

struct **mfxEncoderDescription**

This structure represents an encoder description.

Public Members

mfxStructVersion **Version**

Version of the structure.

mfxU16 **reserved**[7]

Reserved for future use.

mfxU16 **NumCodecs**

Number of supported encoders.

struct *mfxEncoderDescription::encoder* ***Codecs**

Pointer to the array of encoders.

struct **encoder**

This structure represents encoder description.

Public Members

mfxU32 **CodecID**

Encoder ID in FourCC format.

mfxU16 **MaxcodecLevel**

Maximum supported codec level. See the CodecProfile enumerator for possible values.

mfxU16 **BiDirectionalPrediction**

Indicates B-frames support.

mfxU16 **ReportedStats**

Indicates what type of statistics can be reported: block/slice/tile/frame.

mfXU16 **reserved**[6]

Reserved for future use.

mfXU16 **NumProfiles**

Number of supported profiles.

struct *mfXEncoderDescription::encoder::encprofile* ***Profiles**

Pointer to the array of profiles supported by the codec.

struct **encprofile**

This structure represents the codec profile description.

Public Members

mfXU32 **Profile**

Profile ID. See the CodecProfile enumerator for possible values.

mfXU16 **reserved**[7]

Reserved for future use.

mfXU16 **NumMemTypes**

Number of supported memory types.

struct *mfXEncoderDescription::encoder::encprofile::encmemdesc* ***MemDesc**

Pointer to the array of memory types.

struct **encmemdesc**

This structure represents the underlying details of the memory type.

Public Members

mfXResourceType **MemHandleType**

Memory handle type.

mfXRange32U **Width**

Range of supported image widths.

mfXRange32U **Height**

Range of supported image heights.

mfXU16 **reserved**[7]

Reserved for future use.

mfXU16 **NumColorFormats**

Number of supported input color formats.

mfXU32 ***ColorFormats**

Pointer to the array of supported input color formats (in FOURCC).

mfxImplDescription

struct **mfxImplDescription**

This structure represents the implementation description.

Public Members

mfxStructVersion **Version**

Version of the structure.

mfxImplType **Impl**

Impl type: software/hardware.

mfxAccelerationMode **AccelerationMode**

Default Hardware acceleration stack to use. OS dependent parameter. Use VA for Linux* and DX* for Windows*.

mfxVersion **ApiVersion**

Supported API version.

mfxChar **ImplName**[MFX_IMPL_NAME_LEN]

Null-terminated string with implementation name given by vendor.

mfxChar **License**[MFX_STRFIELD_LEN]

Null-terminated string with comma-separated list of license names of the implementation.

mfxChar **Keywords**[MFX_STRFIELD_LEN]

Null-terminated string with comma-separated list of keywords specific to this implementation that dispatcher can search for.

mfxU32 **VendorID**

Standard vendor ID 0x8086 - Intel.

mfxU32 **VendorImplID**

Vendor specific number with given implementation ID.

mfxDeviceDescription **Dev**

Supported device.

mfxDecoderDescription **Dec**

Decoder configuration.

mfxEncoderDescription **Enc**

Encoder configuration.

mfxVPPDescription **VPP**

VPP configuration.

mfxAccelerationModeDescription **AccelerationModeDescription**

Supported acceleration modes.

***mfxPoolPolicyDescription* PoolPolicies**

Supported surface pool polices.

***mfxU32* reserved[8]**

Reserved for future use.

***mfxU32* NumExtParam**

Number of extension buffers. Reserved for future use. Must be 0.

***mfxExtBuffer* **ExtParam**

Array of extension buffers.

***mfxU64* Reserved2**

Reserved for future use.

union ***mfxImplDescription*::[anonymous] ExtParams**

Extension buffers. Reserved for future.

mfxVariantstruct **mfxVariant**The mfxVariantType enumerator data types for *mfxVariant* type.**Public Members*****mfxStructVersion* Version**

Version of the structure.

***mfxVariantType* Type**

Value type.

union ***mfxVariant*::data Data**

Value data member.

union **data**

Value data holder.

Public Members***mfxU8* U8**

mfxU8 data.

***mfxI8* I8**

mfxI8 data.

***mfxU16* U16**

mfxU16 data.

***mfxI16* I16**

mfxI16 data.

***mfxU32* U32**

mfxU32 data.

***mfxI32* I32**

mfxI32 data.

***mfxU64* U64**

mfxU64 data.

***mfxI64* I64**

mfxI64 data.

***mfxF32* F32**

mfxF32 data.

***mfxF64* F64**

mfxF64 data.

mfxFP16 FP16

mfxFP16 data.

***mfxHDL* Ptr**

Pointer. When this points to a string the string must be null terminated.

enum *mfxVariantType*The *mfxVariantType* enumerator data types for *mfxVariantType*.*Values:*enumerator **MF_X_VARIANT_TYPE_UNSET**

Undefined type.

enumerator **MF_X_VARIANT_TYPE_U8**

8-bit unsigned integer.

enumerator **MF_X_VARIANT_TYPE_I8**

8-bit signed integer.

enumerator **MF_X_VARIANT_TYPE_U16**

16-bit unsigned integer.

enumerator **MF_X_VARIANT_TYPE_I16**

16-bit signed integer.

enumerator **MF_X_VARIANT_TYPE_U32**

32-bit unsigned integer.

enumerator **MFx_VARIANT_TYPE_I32**
32-bit signed integer.

enumerator **MFx_VARIANT_TYPE_U64**
64-bit unsigned integer.

enumerator **MFx_VARIANT_TYPE_I64**
64-bit signed integer.

enumerator **MFx_VARIANT_TYPE_F32**
32-bit single precision floating point.

enumerator **MFx_VARIANT_TYPE_F64**
64-bit double precision floating point.

enumerator **MFx_VARIANT_TYPE_PTR**
Generic type pointer.

enumerator **MFx_VARIANT_TYPE_FP16**
16-bit half precision floating point.

mfXVPPDescription

struct **mfXVPPDescription**
This structure represents VPP description.

Public Members

mfXStructVersion **Version**
Version of the structure.

mfXU16 **reserved[7]**
Reserved for future use.

mfXU16 **NumFilters**
Number of supported VPP filters.

struct *mfXVPPDescription::filter* ***Filters**
Pointer to the array of supported filters.

struct **filter**
This structure represents the VPP filters description.

Public Members

mfxU32 **FilterFourCC**

Filter ID in FourCC format.

mfxU16 **MaxDelayInFrames**

Introduced output delay in frames.

mfxU16 **reserved[7]**

Reserved for future use.

mfxU16 **NumMemTypes**

Number of supported memory types.

struct *mfxVPPDescription::filter::memdesc* ***MemDesc**

Pointer to the array of memory types.

struct **memdesc**

This structure represents the underlying details of the memory type.

Public Members

mfxResourceType **MemHandleType**

Memory handle type.

mfxRange32U **Width**

Range of supported image widths.

mfxRange32U **Height**

Range of supported image heights.

mfxU16 **reserved[7]**

Reserved for future use.

mfxU16 **NumInFormats**

Number of supported input color formats.

struct *mfxVPPDescription::filter::memdesc::format* ***Formats**

Pointer to the array of supported formats.

struct **format**

This structure represents the input color format description.

Public Members

mfXU32 **InFormat**

Input color in FourCC format.

mfXU16 **reserved**[5]

Reserved for future use.

mfXU16 **NumOutFormat**

Number of supported output color formats.

mfXU32 ***OutFormats**

Pointer to the array of supported output color formats (in FOURCC).

mfXAccelerationModeDescription

struct **mfXAccelerationModeDescription**

This structure represents acceleration modes description.

Public Members

mfXStructVersion **Version**

Version of the structure.

mfXU16 **reserved**[2]

reserved for future use.

mfXU16 **NumAccelerationModes**

Number of supported acceleration modes.

mfXAccelerationMode ***Mode**

Pointer to the array of supported acceleration modes.

mfXImplementedFunctions

struct **mfXImplementedFunctions**

This structure represents the list of names of implemented functions.

Public Members

mfXU16 **NumFunctions**

Number of function names in the FunctionsName array.

mfXChar ****FunctionsName**

Array of the null-terminated strings. Each string contains name of the implemented function.

mfXExtendedDeviceId

struct **mfXExtendedDeviceId**

Specifies various physical device properties for device matching and identification outside of oneVPL.

Public Members

mfXStructVersion **Version**

Version of the structure.

mfXU16 **VendorID**

PCI vendor ID.

mfXU16 **DeviceID**

PCI device ID.

mfXU32 **PCIDomain**

PCI bus domain. Equals to '0' if OS doesn't support it or has sequential numbering of buses across domains.

mfXU32 **PCIBus**

The number of the bus that the physical device is located on.

mfXU32 **PCIDevice**

The index of the physical device on the bus.

mfXU32 **PCIFunction**

The function number of the device on the physical device.

mfXU8 **DeviceLUID[8]**

LUID of DXGI adapter.

mfXU32 **LUIDDeviceNodeMask**

Bitfield identifying the node within a linked device adapter corresponding to the device.

mfXU32 **LUIDValid**

Boolean value that will be 1 if DeviceLUID contains a valid LUID and LUIDDeviceNodeMask contains a valid node mask, and 0 if they do not.

mfXU32 **DRMRenderNodeNum**

Number of the DRM render node from the path /dev/dri/RenderD<num>. Value equals to 0 means that this field doesn't contain valid DRM Render Node number.

***mfXU32* DRMPrimaryNodeNum**

Number of the DRM primary node from the path /dev/dri/card<num>. Value equals to 0x7FFFFFFF means that this field doesn't contain valid DRM Primary Node number.

***mfXU8* reserved1[20]**

Reserved for future use.

***mfXChar* DeviceName[MFX_STRFIELD_LEN]**

Null-terminated string in utf-8 with the name of the device.

mfXPoolPolicyDescription**struct mfXPoolPolicyDescription**

This structure represents pool policy description.

Public Members***mfXStructVersion* Version**

Version of the structure.

***mfXU16* reserved[2]**

reserved for future use.

***mfXU16* NumPoolPolicies**

Number of supported pool policies.

***mfXPoolAllocationPolicy* *Policy**

Pointer to the array of supported pool policies.

Dispatcher API Enumeration Reference**API**

- *mfXAccelerationMode*
- *mfXImplType*

mfxAccelerationMode

enum **mfxAccelerationMode**

This enum itemizes hardware acceleration stack to use.

Values:

enumerator **MFX_ACCEL_MODE_NA**

Hardware acceleration is not applicable.

enumerator **MFX_ACCEL_MODE_VIA_D3D9**

Hardware acceleration goes through the Microsoft* Direct3D9* infrastructure.

enumerator **MFX_ACCEL_MODE_VIA_D3D11**

Hardware acceleration goes through the Microsoft* Direct3D11* infrastructure.

enumerator **MFX_ACCEL_MODE_VIA_VAAPI**

Hardware acceleration goes through the Linux* VA-API infrastructure.

enumerator **MFX_ACCEL_MODE_VIA_VAAPI_DRM_RENDER_MODE**

Hardware acceleration goes through the Linux* VA-API infrastructure with DRM RENDER MODE as default acceleration access point.

enumerator **MFX_ACCEL_MODE_VIA_VAAPI_DRM_MODESET**

Hardware acceleration goes through the Linux* VA-API infrastructure with DRM MODESET as default acceleration access point.

enumerator **MFX_ACCEL_MODE_VIA_VAAPI_GLX**

enumerator **MFX_ACCEL_MODE_VIA_VAAPI_X11**

Hardware acceleration goes through the Linux* VA-API infrastructure with OpenGL Extension to the X Window System as default acceleration access point. Hardware acceleration goes through the Linux* VA-API infrastructure with X11 as default acceleration access point.

enumerator **MFX_ACCEL_MODE_VIA_VAAPI_WAYLAND**

Hardware acceleration goes through the Linux* VA-API infrastructure with Wayland as default acceleration access point.

enumerator **MFX_ACCEL_MODE_VIA_HDDLUNITE**

Hardware acceleration goes through the HDDL* Unite*.

mfxImplType

enum **mfxImplType**

This enum itemizes implementation type.

Values:

enumerator **MFX_IMPL_TYPE_SOFTWARE**

Pure Software Implementation.

enumerator **MFX_IMPL_TYPE_HARDWARE**
Hardware Accelerated Implementation.

MFX_IMPL_NAME_LEN

MFX_IMPL_NAME_LEN

Maximum allowed length of the implementation name.

MFX_STRFIELD_LEN

MFX_STRFIELD_LEN

Maximum allowed length of the implementation name.

Helper macro definitions to add property with single value.

MFX_ADD_PROPERTY_U32

MFX_ADD_PROPERTY_U32(loader, name, value)

Adds single property of mfxU32 type.

Parameters

- **loader** – [in] Valid mfxLoader object
- **name** – [in] Property name string
- **value** – [in] Property value

MFX_ADD_PROPERTY_U16

MFX_ADD_PROPERTY_U16(loader, name, value)

Adds single property of mfxU16 type.

Parameters

- **loader** – [in] Valid mfxLoader object
- **name** – [in] Property name string
- **value** – [in] Property value

MFX_ADD_PROPERTY_PTR

MFX_ADD_PROPERTY_PTR(loader, name, value)

Adds single property of pointer type.

Parameters

- **loader** – [in] Valid mfxLoader object
- **name** – [in] Property name string
- **value** – [in] Property value

Helper macro definitions to update existing property.

MFX_UPDATE_PROPERTY_U32

MFX_UPDATE_PROPERTY_U32(loader, config, name, value)

Update existing property of mfxU32 type.

Parameters

- **loader** – [in] Valid mfxLoader object
- **config** – [in] Valid mfxConfig object
- **name** – [in] Property name string
- **value** – [in] Property value

MFX_UPDATE_PROPERTY_U16

MFX_UPDATE_PROPERTY_U16(loader, config, name, value)

Update existing property of mfxU16 type.

Parameters

- **loader** – [in] Valid mfxLoader object
- **config** – [in] Valid mfxConfig object
- **name** – [in] Property name string
- **value** – [in] Property value

MFX_UPDATE_PROPERTY_PTR

MFX_UPDATE_PROPERTY_PTR(loader, config, name, value)
Update existing property of pointer type.

Parameters

- **loader** – [in] Valid mfxLoader object
- **config** – [in] Valid mfxConfig object
- **name** – [in] Property name string
- **value** – [in] Property value

10.5.7 GUIDs Reference

API

0xec, 0xb1, 0x15, 0x08, 0x06, 0xb1}}
```

GUID to obtain *mfxSurfacePoolInterface*.

10.6 oneVPL API Versioning

oneVPL is the successor to Intel® Media Software Development Kit. oneVPL API versioning starts from 2.0. There is a correspondent version of Intel® Media Software Development Kit API which is used as a basis for oneVPL and defined as the `MFX_LEGACY_VERSION` macro.

10.7 oneVPL Experimental API

All API entries defined under the `ONEVPL_EXPERIMENTAL` macro are considered as experimental. Backward compatibility is not guaranteed for these features. Future presence is not guaranteed as well.

By default, experimental API is turned off in the header files. To enable it, need to define `ONEVPL_EXPERIMENTAL` macro during the application compilation stage.

The following is a list of experimental interfaces, starting from API version 2.6.

Table 15: Experimental API

Experimental API	Added in API Version	Removed in API Version	Removal Reason
<i>mfxEtendedDeviceId</i>	2.6		
<i>mfxEtCodingOption3::CPUEncToolsProcessing</i>	2.6		
<i>mfxEtRefListCtrl</i>	2.6	2.8	Moved to production
<i>MFX_EXTBUFF_UNIVERSAL_REFLIST_CTRL</i>	2.6	2.8	Moved to production
Extended enum for <i>mfxEtDecodeErrorReport::ErrorTypes</i>	2.6	2.7	Moved to production
<i>mfxEtHandleType::MFX_HANDLE_PXP_CONTEXT</i>	2.6	2.7	Moved to production
<i>mfxEtRefInterface</i>	2.7		
All definitions in <i>mfxEtcodestats.h</i>	2.7		
<i>MFX_FOURCC_ABGR16F</i> FourCC definition	2.8		
<i>MFX_CONTENT_NOISY_VIDEO</i> ContentInfo definition	2.8		
Camera Processing API for RAW acceleration	2.8		
Hint to disable external video frames caching for GPU copy	2.8		
<i>mfxEtMBQP::Pitch</i>	2.8

10.8.1 Configuration Parameter Constraints

The *mfxEtFrameInfo* structure is used by both the *mfxEtVideoParam* structure during oneVPL class initialization and the *mfxEtFrameSurface1* structure during the actual oneVPL class operation. The parameter constraints described in the following tables apply.

DECODE, ENCODE, and VPP Constraints

The *DECODE, ENCODE, and VPP Constraints* table lists parameter constraints common to *DECODE*, *ENCODE*, and *VPP*.

Table 16: DECODE, ENCODE, and VPP Constraints

Parameters	Use During Initialization	Use During Operation
FourCC	Any valid value.	The value must be the same as the initialization value. The only exception is <i>VPP</i> in composition mode, where in some cases it is allowed to mix RGB and NV12 surfaces. See <i>mfxEtVPPComposite</i> for more details.
ChromaFormat	Any valid value.	The value must be the same as the initialization value.

DECODE Constraints

The *DECODE Constraints table* lists *DECODE* parameter constraints.

Table 17: DECODE Constraints

Parameters	Use During Initialization	Use During Operation
Width, Height	Aligned frame size.	The values must be the equal to or larger than the initialization values.
CropX, CropY CropW, CropH	Ignored.	<i>DECODE</i> output. The cropping values are per-frame based.
AspectRatioW, AspectRatioH	Any valid values or unspecified (zero); if unspecified, values from the input bitstream will be used. See note below the table.	DECODE output.
FrameRateExtN, FrameRateExtD	If unspecified, values from the input bitstream will be used. See note below the table.	DECODE output.
PicStruct	Ignored.	DECODE output.

Note: If the application explicitly sets FrameRateExtN/FrameRateExtD or AspectRatioW/AspectRatioH during initialization, then the decoder will use these values during decoding regardless of the values from bitstream and does not update them on new SPS. If the application sets them to 0, then the decoder uses values from the stream and updates them on each SPS.

ENCODE Constraints

The *ENCODE Constraints table* lists *ENCODE* parameter constraints.

Table 18: ENCODE Constraints

Parameters	Use During Initialization	Use During Operation
Width, Height	Encoded frame size.	The values must be the equal to or larger than the initialization values.
CropX, CropY CropW, CropH	H.264: Cropped frame size MPEG-2: CropW and CropH Specify the real width and height (may be unaligned) of the coded frames. CropX and CropY must be zero.	Ignored.
AspectRatioW, AspectRatioH	Any valid values.	Ignored.
FrameRateExtN, FrameRateExtD	Any valid values.	Ignored.
PicStruct	<i>MFx_PICSTRUCT_UNKNOWN</i> <i>MFx_PICSTRUCT_PROGRESSIVE</i> <i>MFx_PICSTRUCT_FIELD_TFF</i> <i>MFx_PICSTRUCT_FIELD_BFF</i>	The base value must be the same as the initialization value unless <i>MFx_PICSTRUCT_UNKNOWN</i> is specified during initialization. Add other decorative picture structure flags to indicate additional display attributes. Use <i>MFx_PICSTRUCT_UNKNOWN</i> during initialization for field attributes and <i>MFx_PICSTRUCT_PROGRESSIVE</i> for frame attributes. See the <i>PicStruct</i> enumerator for details.

VPP Constraints

The *VPP Constraints table* lists *VPP* parameter constraints.

Table 19: VPP Constraints

Parameters	During Initialization	During Operation
Width, Height	Any valid values	The values must be the equal to or larger than the initialization values.
CropX, CropY, CropW, CropH	Ignored	These parameters specify the region of interest from input to output.
AspectRatioW, AspectRatioH	Ignored	Aspect ratio values will be passed through from input to output.
FrameRateExtN, FrameRateExtD	Any valid values	Frame rate values will be updated with the initialization value at output.
PicStruct	<i>MFx_PICSTRUCT_UNKNOWN</i> <i>MFx_PICSTRUCT_PROGRESSIVE</i> <i>MFx_PICSTRUCT_FIELD_TFF</i> <i>MFx_PICSTRUCT_FIELD_BFF</i> <i>MFx_PICSTRUCT_FIELD_SINGLE</i> <i>MFx_PICSTRUCT_FIELD_TOP</i> <i>MFx_PICSTRUCT_FIELD_BOTTOM</i>	The base value must be the same as the initialization value unless <i>MFx_PICSTRUCT_UNKNOWN</i> is specified during initialization. Other decorative picture structure flags are passed through or added as needed. See the <i>PicStruct</i> enumerator for details.

Specifying Configuration Parameters

The following *Configuration Parameters tables* summarize how to specify the configuration parameters during initialization, encoding, decoding, and video processing.

Table 20: mfxVideoParam Configuration Parameters

Structure (param)	ENCODE Init	ENCODE Encoding	DECODE Init	DECODE Decoding	VPP Init	VPP Processing
Protected	R	.	R	.	R	.
IOPattern	M	.	M	.	M	.
ExtParam	O	.	O	.	O	.
Nu-mExtParam	O	.	O	.	O	.

Table 21: mfxInfoMFX Configuration Parameters

Structure (param)	ENCODE Init	ENCODE Encoding	DECODE Init	DECODE Decoding	VPP Init	VPP Processing
CodecId	M	.	M	.	.	.
CodecProfile	O	.	O/M*	.	.	.
CodecLevel	O	.	O	.	.	.
NumThread	O	.	O	.	.	.
TargetUsage	O
GopPicSize	O
GopRefDist	O
GopOptFlag	O
IdrInterval	O
RateControl-Method	O
InitialDelayInKB	O
BufferSizeInKB	O
TargetKbps	M
MaxKbps	O
NumSlice	O
NumRefFrame	O
EncodedOrder	M

Table 22: mfxFrameInfo Configuration Parameters

Structure (param)	ENCODE Init	ENCODE Encoding	DECODE Init	DECODE Decoding	VPP Init	VPP Processing
FourCC	M	M	M	M	M	M
Width	M	M	M	M	M	M
Height	M	M	M	M	M	M
CropX	M	Ign	Ign	U	Ign	M
CropY	M	Ign	Ign	U	Ign	M
CropW	M	Ign	Ign	U	Ign	M
CropH	M	Ign	Ign	U	Ign	M
FrameRateExtN	M	Ign	O	U	M	U
FrameRateExtD	M	Ign	O	U	M	U
AspectRatioW	O	Ign	O	U	Ign	PT
AspectRatioH	O	Ign	O	U	Ign	PT
PicStruct	O	M	Ign	U	M	M/U
ChromaFormat	M	M	M	M	Ign	Ign

Table 23: Abbreviations used in configuration parameter tables

Abbreviation	Meaning
Ign	Ignored
PT	Pass Through
•	Does Not Apply
M	Mandated
R	Reserved
O	Optional
U	Updated at output

Note: *CodecProfile* is mandated for HEVC REXT and SCC profiles and optional for other cases. If the application does not explicitly set *CodecProfile* during initialization, the HEVC decoder will use a profile up to Main10.

10.8.2 Multiple-segment Encoding

Multiple-segment encoding is useful in video editing applications during production, for example when the encoder encodes multiple video clips according to their time line. In general, one can define multiple-segment encoding as dividing an input sequence of frames into segments and encoding them in different encoding sessions with the same or different parameter sets. For example:

Segment Already Encoded	Segment in Encoding	Segment to be Encoded
0s	200s	500s

Note: Different encoders can also be used.

The application must be able to:

- Extract encoding parameters from the bitstream of previously encoded segment.
- Import these encoding parameters to configure the encoder.

Encoding can then continue on the current segment using either the same or similar encoding parameters.

Extracting the header that contains the encoding parameter set from the encoded bitstream is usually the task of a format splitter (de-multiplexer). Alternatively, the `MFVideoENCODE_DecodeHeader()` function can export the raw header if the application attaches the `mfxExtCodingOptionSPSPPS` structure as part of the parameters.

The encoder can use the `mfxExtCodingOptionSPSPPS` structure to import the encoding parameters during `MFVideoENCODE_Init()`. The encoding parameters are in the encoded bitstream format. Upon a successful import of the header parameters, the encoder will generate bitstreams with a compatible (not necessarily bit-exact) header. The *Header Import Functions table* shows all functions that can import a header and their error codes if there are unsupported parameters in the header or the encoder is unable to achieve compatibility with the imported header.

Table 24: Header Import Functions

Function Name	Error Code if Import Fails
<code>MFVideoENCODE_Init()</code>	<code>MF_ERR_INCOMPATIBLE_VIDEO_PARAM</code>
<code>MFVideoENCODE_QueryIOSurf()</code>	<code>MF_ERR_INCOMPATIBLE_VIDEO_PARAM</code>
<code>MFVideoENCODE_Reset()</code>	<code>MF_ERR_INCOMPATIBLE_VIDEO_PARAM</code>
<code>MFVideoENCODE_Query()</code>	<code>MF_ERR_UNSUPPORTED</code>

The encoder must encode frames to a GOP sequence starting with an IDR frame for H.264 (or I frame for MPEG-2) to ensure that the current segment encoding does not refer to any frames in the previous segment. This ensures that the encoded segment is self-contained, allowing the application to insert the segment anywhere in the final bitstream. After encoding, each encoded segment is HRD compliant. Concatenated segments may not be HRD compliant.

The following example shows the encoder initialization procedure that imports H.264 sequence and picture parameter sets:

```

1 mfxStatus init_encoder() {
2     mfxExtCodingOptionSPSPPS option, *option_array;
3
4     /* configure mfxExtCodingOptionSPSPPS */
5     memset(&option,0,sizeof(option));
6     option.Header.BufferId=MF_EXTBUFF_CODING_OPTION_SPSPPS;
7     option.Header.BufferSz=sizeof(option);
8     option.SPSBuffer=sps_buffer;
9     option.SPSBufSize=sps_buffer_length;
10    option.PPSBuffer=pps_buffer;
11    option.PPSBufSize=pps_buffer_length;
12
13    /* configure mfxVideoParam */
14    mfxVideoParam param;
15    //...
16    param.NumExtParam=1;
17    option_array=&option;
18    param.ExtParam=(mfxExtBuffer**)&option_array;
19
20    /* encoder initialization */
21    mfxStatus status;
22    status=MFVideoENCODE_Init(session, &param);
23    if (status==MF_ERR_INCOMPATIBLE_VIDEO_PARAM) {

```

(continues on next page)

(continued from previous page)

```
24     printf("Initialization failed.\n");
25 } else {
26     printf("Initialized.\n");
27 }
28 return status;
29 }
```

10.8.3 Streaming and Video Conferencing Features

The following sections address some aspects of additional requirements that streaming or video conferencing applications may use in the encoding or transcoding process. See the *Configuration Change* section for additional information.

Dynamic Bitrate Change

The oneVPL encoder supports dynamic bitrate change according to bitrate control mode and HRD conformance requirements. If HRD conformance is required, for example if the application sets the `Na1HrdConformance` option in the `mfxExtCodingOption` structure to ON, the only allowed bitrate control mode is VBR. In this mode, the application can change the `TargetKbps` and `MaxKbps` values of the `mfxInfoMFX` structure by calling the `MFVideoENCODE_Reset()` function. This sort of change in bitrate usually results in the generation of a new keyframe and sequence header. There are exceptions, such as if HRD information is absent in the stream. In this scenario, the change of `TargetKbps` does not require a change in the sequence header and as a result the encoder does not insert a keyframe.

If HRD conformance is not required, for example if the application turns off the `Na1HrdConformance` option in the `mfxExtCodingOption` structure, all bitrate control modes are available. In CBR and AVBR modes the application can change `TargetKbps`. In VBR mode the application can change `TargetKbps` and `MaxKbps` values. This sort of change in bitrate will not result in the generation of a new keyframe or sequence header.

The oneVPL encoder may change some initialization parameters provided by the application during initialization. That in turn may lead to incompatibility between the parameters provided by the application during reset and the working set of parameters used by the encoder. For this reason, it is strongly recommended to retrieve the actual working parameters using the `MFVideoENCODE_GetVideoParam()` function before making any changes to bitrate settings.

In all modes, oneVPL encoders will respond to the bitrate changes as quickly as the underlying algorithm allows, without breaking other encoding restrictions such as HRD compliance if it is enabled. How quickly the actual bitrate can catch up with the specified bitrate is implementation dependent.

Alternatively, the application may use the *CQP* encoding mode to perform customized bitrate adjustment on a per-frame base. The application may use any of the encoded or display order modes to use per-frame CQP.

Dynamic Resolution Change

The oneVPL encoder supports dynamic resolution change in all bitrate control modes. The application may change resolution by calling the `MFVideoENCODE_Reset()` function. The application may decrease or increase resolution up to the size specified during encoder initialization.

Resolution change always results in the insertion of a key IDR frame and a new sequence parameter set in the header. The only exception is the oneVPL VP9 encoder (see section for *Dynamic reference frame scaling*). The oneVPL encoder does not guarantee HRD conformance across the resolution change point.

The oneVPL encoder may change some initialization parameters provided by the application during initialization. That in turn may lead to incompatibility of parameters provide by the application during reset and working set of parameters used by the encoder. Due to this potential incompatibility, it is strongly recommended to retrieve the actual working parameters set by `MFVideoENCODE_GetVideoParam()` function before making any resolution change.

Dynamic Reference Frame Scaling

The VP9 standard allows changing the resolution without the insertion of a keyframe. This is possible because the VP9 encoder has the built-in capability to upscale and downscale reference frames to match the resolution of the frame being encoded. By default the oneVPL VP9 encoder inserts a keyframe when the application does *Dynamic Resolution Change*. In this case, the first frame with a new resolution is encoded using inter prediction from the scaled reference frame of the previous resolution. Dynamic scaling has the following limitations, described in the VP9 specification:

- The resolution of any active reference frame cannot exceed 2x the resolution of the current frame.
- The resolution of any active reference frame cannot be smaller than 1/16 of the current frame resolution.

In the case of dynamic scaling, the oneVPL VP9 encoder always uses a single active reference frame for the first frame after a resolution change. The VP9 encoder has the following limitations for dynamic resolution change:

- The new resolution should not exceed 16x the resolution of the current frame.
- The new resolution should be less than 1/2 of current frame resolution.

The application may force insertion of a keyframe at the point of resolution change by invoking encoder reset with *mfExtEncoderResetOption::StartNewSequence* set to *MFX_CODINGOPTION_ON*. If a keyframe is inserted, the dynamic resolution limitations are not enforced.

Note that resolution change with dynamic reference scaling is compatible with multiref (*mfInfoMFX::NumRefFrame* > 1). For multiref configuration, the oneVPL VP9 encoder uses multiple references within stream pieces of the same resolution and uses a single reference at the place of resolution change.

Forced Keyframe Generation

oneVPL supports forced keyframe generation during encoding. The application can set the *FrameType* parameter of the *mfxEncodeCtrl* structure to control how the current frame is encoded, as follows:

- If the oneVPL encoder works in the display order, the application can enforce any current frame to be a keyframe. The application cannot change the frame type of already buffered frames inside the encoder.
- If the oneVPL encoder works in the encoded order, the application must specify exact frame type for every frame. In this way, the application can enforce the current frame to have any frame type that the particular coding standard allows.

Reference List Selection

During streaming or video conferencing, if the application can obtain feedback about how well the client receives certain frames, the application may need to adjust the encoding process to use or not use certain frames as reference. This section describes how to fine-tune the encoding process based on client feedback.

The application can specify the reference window size by specifying the *mfInfoMFX::NumRefFrame* parameter during encoding initialization. Certain platforms may have limits on the size of the reference window. Use the *MFXVideoENCODE_GetVideoParam()* function to retrieve the current working set of parameters.

During encoding, the application can specify the actual reference list lengths by attaching the *mfExtAVCRefListCtrl* structure to the *MFXVideoENCODE_EncodeFrameAsync()* function. *NumRefIdxL0Active* specifies the length of the reference list L0 and *NumRefIdxL1Active* specifies the length of the reference list L1. These two numbers must be less than or equal to the *mfInfoMFX::NumRefFrame* parameter during encoding initialization.

The application can instruct the oneVPL encoder to use or not use certain reference frames. To do this, there is a prerequisite that the application uniquely identify each input frame by setting the *mfFrameData::FrameOrder* parameter. The application then specifies the preferred reference frame list *PreferredRefList* and/or the rejected frame list *RejectedRefList*, and attaches the *mfExtAVCRefListCtrl*

structure to the `MFxVideoENCODE_EncodeFrameAsync()` function. The two lists fine-tune how the encoder chooses the reference frames for the current frame. The encoder does not keep `PreferredRefList` and the application must send it for each frame if necessary. There are limitations as follows:

- The frames in the lists are ignored if they are out of the reference window.
- If by going through the lists, the oneVPL encoder cannot find a reference frame for the current frame, the encoder will encode the current frame without using any reference frames.
- If the GOP pattern contains B-frames, the oneVPL encoder may not be able to follow the `mfExtAVCRefListCtrl` instructions.

Low Latency Encoding and Decoding

The application can set `mfVideoParam::AsyncDepth = 1` to disable any decoder buffering of output frames, which is aimed to improve the transcoding throughput. With `mfVideoParam::AsyncDepth = 1`, the application must synchronize after the decoding or transcoding operation of each frame.

The application can adjust `mfExtCodingOption::MaxDecFrameBuffering` during encoding initialization to improve decoding latency. It is recommended to set this value equal to the number of reference frames.

Reference Picture Marking Repetition SEI Message

The application can request writing the reference picture marking repetition SEI message during encoding initialization by setting `RefPicMarkRep` of the `mfExtCodingOption` structure. The reference picture marking repetition SEI message repeats certain reference frame information in the output bitstream for robust streaming.

The oneVPL decoder will respond to the reference picture marking repetition SEI message if the message exists in the bitstream and compare it to the reference list information specified in the sequence/picture headers. The decoder will report any mismatch of the SEI message with the reference list information in the `mfFrameData::Corrupted` field.

Long Term Reference Frame

The application may use long term reference frames to improve coding efficiency or robustness for video conferencing applications. The application controls the long term frame marking process by attaching the `mfExtAVCRefListCtrl` extended buffer during encoding. The oneVPL encoder itself never marks a frame as long term.

There are two control lists in the `mfExtAVCRefListCtrl` extended buffer. The `LongTermRefList` list contains the frame orders (the `FrameOrder` value in the `mfFrameData` structure) of the frames that should be marked as long term frames. The `RejectedRefList` list contains the frame order of the frames that should be unmarked as long term frames. The application can only mark or unmark the frames that are buffered inside the encoder. Because of this, it is recommended that the application marks a frame when it is submitted for encoding. The application can either explicitly unmark long term reference frames or wait for the IDR frame. When the IDR frame is reached, all long term reference frames will be unmarked.

The oneVPL encoder puts all long term reference frames at the end of a reference frame list. If the number of active reference frames (the `NumRefIdxL0Active` and `NumRefIdxL1Active` values in the `mfExtAVCRefListCtrl` extended buffer) is less than the total reference frame number (the `NumRefFrame` value in the `mfInfoMFX` structure during the encoding initialization), the encoder may ignore some or all long term reference frames. The application may avoid this by providing a list of preferred reference frames in the `PreferredRefList` list in the `mfExtAVCRefListCtrl` extended buffer. In this case, the encoder reorders the reference list based on the specified list.

Temporal Scalability

The application may specify the temporal hierarchy of frames by using the *mfExtAvcTemporalLayers* extended buffer during the encoder initialization in the display order encoding mode. oneVPL inserts the prefix NAL unit before each slice with a unique temporal and priority ID. The temporal ID starts from zero and the priority ID starts from the BaseLayerPID value. oneVPL increases the temporal ID and priority ID value by one for each consecutive layer.

If the application needs to specify a unique sequence or picture parameter set ID, the application must use the *mfExtCodingOptionSPSPPS* extended buffer, with all pointers and sizes set to zero and valid SPSId and PPSId fields. The same SPS and PPS ID will be used for all temporal layers.

Each temporal layer is a set of frames with the same temporal ID. Each layer is defined by the Scale value. The scale for layer N is equal to the ratio between the frame rate of subsequent temporal layers with a temporal ID less than or equal to N and the frame rate of the base temporal layer. The application may skip some temporal layers by specifying the Scale value as zero. The application should use an integer ratio of the frame rates for two consecutive temporal layers.

For example, a video sequence with 30 frames/second is typically separated by three temporal layers that can be decoded as 7.5 fps (base layer), 15 fps (base and first temporal layer) and 30 fps (all three layers). In this scenario, Scale should have the values {1,2,4,0,0,0,0}.

10.8.4 Switchable Graphics and Multiple Monitors

The following sections discuss support for switchable graphics and multiple monitor configurations.

Switchable Graphics

Switchable Graphics refers to the machine configuration that multiple graphic devices are available (integrated device for power saving and discrete devices for performance.) Usually at one time or instance, one of the graphic devices drives display and becomes the active device, and others become inactive. There are different variations of software or hardware mechanisms to switch between the graphic devices. In one of the switchable graphics variations, it is possible to register an application in an affinity list to certain graphic device so that the launch of the application automatically triggers a switch. The actual techniques to enable such a switch are outside the scope of this document. This section discusses the implication of switchable graphics to Intel® Media Software Development Kit and Intel® Media Software Development Kit applications.

As Intel® Media Software Development Kit performs hardware acceleration through graphic devices, it is critical that Intel® Media Software Development Kit can access the graphic device in the switchable graphics setting. It is recommended to add the application to the graphic device affinity list. If this is not possible, the application should handle the following cases:

- By design, during legacy Intel® Media Software Development Kit library initialization, the *MFXInit()* function searches for graphic devices. If a Intel® Media Software Development Kit implementation is successfully loaded, the *MFXInit()* function returns *mfxStatus::MFX_ERR_NONE* and the *MFXQueryIMPL()* function returns the actual implementation type. If no Intel® Media Software Development Kit implementation is loaded, the *MFXInit()* function returns *mfxStatus::MFX_ERR_UNSUPPORTED*. In the switchable graphics environment, if the application is not in the graphic device affinity list, it is possible that the graphic device will not be accessible during the library initialization. The fact that the *MFXInit()* function returns *mfxStatus::MFX_ERR_UNSUPPORTED* does not mean that hardware acceleration is permanently impossible. The user may switch the graphics later and the graphic device will become accessible. It is recommended that the application initialize the library right before the actual decoding, video processing, and encoding operations to determine the hardware acceleration capability.
- During decoding, video processing, and encoding operations, if the application is not in the graphic device affinity list, the previously accessible graphic device may become inaccessible due to a switch event.

The Intel® Media Software Development Kit functions will return `mfStatus::MFX_ERR_DEVICE_LOST` or `mfStatus::MFX_ERR_DEVICE_FAILED`, depending on when the switch occurs and what stage the Intel® Media Software Development Kit functions operate. The application should handle these errors and exit gracefully.

Multiple Monitors

Multiple monitors refer to the machine configuration that multiple graphic devices are available. Some graphic devices connect to a display and become active and accessible under the Microsoft* DirectX* infrastructure. Graphic devices that are not connected to a display are inactive. Using the Microsoft Direct3D* 9 infrastructure, devices that are not connected to a display are not accessible.

The legacy Intel® Media Software Development Kit uses the adapter number to access a specific graphic device. Usually, the graphic device driving the main desktop becomes the primary adapter. Other graphic devices take subsequent adapter numbers after the primary adapter. Under the Microsoft Direct3D 9 infrastructure, only active adapters are accessible and have an adapter number.

Intel® Media Software Development Kit extends the `mfImpl` implementation type as shown in the *Intel® Media SDK mfxImpl Implementation Type Definitions table*:

Table 25: Intel® Media SDK mfxImpl Implementation Type Definitions

Implementation Type	Definition
<code>MFX_IMPL_HARDWARE</code>	Intel® Media Software Development Kit should initialize on the primary adapter
<code>MFX_IMPL_HARDWARE2</code>	Intel® Media Software Development Kit should initialize on the 2nd graphic adapter
<code>MFX_IMPL_HARDWARE3</code>	Intel® Media Software Development Kit should initialize on the 3rd graphic adapter
<code>MFX_IMPL_HARDWARE4</code>	Intel® Media Software Development Kit should initialize on the 4th graphic adapter
<code>MFX_IMPL_HARDWARE_ANY</code>	Intel® Media Software Development Kit should initialize on any graphic adapter.
<code>MFX_IMPL_AUTO_ANY</code>	Intel® Media Software Development Kit should initialize on any graphic adapter. If not successful, load the software implementation.

The application can use the first four definitions shown in the *Intel® Media SDK mfxImpl Implementation Type Definitions table* to instruct the legacy Intel® Media Software Development Kit library to initialize on a specific graphic device. The application can use the definitions for `MFX_IMPL_HARDWARE_ANY` and `MFX_IMPL_AUTO_ANY` for automatic detection.

If the application uses the Microsoft DirectX surfaces for I/O, it is critical that the application and Intel® Media Software Development Kit work on the same graphic device. It is recommended that the application use the following procedure:

1. The application uses the `MFXInit()` function to initialize the legacy Intel® Media Software Development Kit, with option `MFX_IMPL_HARDWARE_ANY` or `MFX_IMPL_AUTO_ANY`. The `MFXInit()` function returns `mfStatus::MFX_ERR_NONE` if successful.
2. The application uses the `MFXQueryImpl()` function to check the actual implementation type. The implementation type `MFX_IMPL_HARDWARE`, `MFX_IMPL_HARDWARE2`, `MFX_IMPL_HARDWARE3`, or `MFX_IMPL_HARDWARE4` indicates the graphic adapter the Intel® Media Software Development Kit works on.
3. The application creates the Direct3D device on the respective graphic adapter and passes it to Intel® Media Software Development Kit through the `MFXVideoCORE_SetHandle()` function.

Similar to the switchable graphics cases, interruption may result if the user disconnects monitors from the graphic devices or remaps the primary adapter. If the interruption occurs during the Intel® Media Software Development Kit

library initialization, the `MFXInit()` function may return `mfxStatus::MFX_ERR_UNSUPPORTED`. This means hardware acceleration is currently not available. It is recommended that the application initialize Intel® Media Software Development Kit right before the actual decoding, video processing, and encoding operations to determine the hardware acceleration capability.

If the interruption occurs during decoding, video processing, or encoding operations, oneVPL functions will return `mfxStatus::MFX_ERR_DEVICE_LOST` or `mfxStatus::MFX_ERR_DEVICE_FAILED`. The application should handle these errors and exit gracefully.

10.8.5 Working Directly with VA API for Linux*

Intel® Media Software Development Kit takes care of all memory and synchronization related operations in the VA API. The application may need to extend Intel® Media Software Development Kit functionality by working directly with the VA API for Linux*, for example to implement a customized external allocator. This section describes basic memory management and synchronization techniques.

To create the VA surface pool, the application should call the `vaCreateSurfaces` function:

```

1  const int num_surfaces = 5;
2  VASurfaceID surfaces[num_surfaces];
3  VASurfaceAttrib attrib;
4
5  attrib.type = VASurfaceAttribPixelFormat;
6  attrib.value.type = VAGenericValueTypeInteger;
7  attrib.value.value.i = VA_FOURCC_NV12;
8  attrib.flags = VA_SURFACE_ATTRIB_SETTABLE;
9
10 vaCreateSurfaces(va_display, VA_RT_FORMAT_YUV420, width, height,
11                 surfaces, num_surfaces, &attrib, 1);

```

To destroy the surface pool, the application should call the `vaDestroySurfaces` function:

```

1  vaDestroySurfaces(va_display, surfaces, num_surfaces);

```

If the application works with hardware acceleration through Intel® Media Software Development Kit, then it can access surface data immediately after successful completion of the `MFXVideoCORE_SyncOperation()` call. If the application works with hardware acceleration directly, then it must check surface status before accessing data in video memory. This check can be done asynchronously by calling the `vaQuerySurfaceStatus` function or synchronously by calling the `vaSyncSurface` function.

After successful synchronization, the application can access surface data. Accessing surface data is performed in two steps:

1. Create `VAIImage` from surface.
2. Map image buffer to system memory.

After mapping, the `VAIImage.offsets[3]` array holds offsets to each color plain in a mapped buffer and the `VAIImage.pitches[3]` array holds color plain pitches in bytes. For packed data formats, only first entries in these arrays are valid. The following example shows how to access data in a NV12 surface:

```

1  VAIImage image;
2  unsigned char *Y, *U, *V;
3  void* buffer;
4
5  vaDeriveImage(va_display, surfaceToMap, &image);

```

(continues on next page)

(continued from previous page)

```

6 vaMapBuffer(va_display, image.buf, &buffer);
7
8 /* NV12 */
9 Y = (unsigned char*)buffer + image.offsets[0];
10 U = (unsigned char*)buffer + image.offsets[1];
11 V = U + 1;

```

After processing data in a VA surface, the application should release resources allocated for the mapped buffer and VAImage object:

```

1 vaUnmapBuffer(va_display, image.buf);
2 vaDestroyImage(va_display, image.image_id);

```

In some cases, in order to retrieve encoded bitstream data from video memory, the application must use the VABuffer to store data. The following example shows how to create, use, and destroy the VABuffer:

```

1 VABufferID buf_id;
2 size_t size;
3 uint32_t offset;
4 void *buf;
5
6 /* create buffer */
7 vaCreateBuffer(va_display, va_context, VAEncCodedBufferType, buf_size, 1, NULL, & buf_
  ↳ id);
8
9 /* encode frame */
10 // ...
11
12 /* map buffer */
13 VACodedBufferSegment *coded_buffer_segment;
14
15 vaMapBuffer(va_display, buf_id, (void **>(&coded_buffer_segment));
16
17 size = coded_buffer_segment->size;
18 offset = coded_buffer_segment->bit_offset;
19 buf = coded_buffer_segment->buf;
20
21 /* retrieve encoded data*/
22 // ...
23
24 /* unmap and destroy buffer */
25 vaUnmapBuffer(va_display, buf_id);
26 vaDestroyBuffer(va_display, buf_id);

```

Note that the vaMapBuffer function returns pointers to different objects depending on the mapped buffer type. The VAImage is a plain data buffer and the encoded bitstream is a VACodedBufferSegment structure. The application cannot use VABuffer for synchronization. If encoding, it is recommended to synchronize using the VA surface as described above.

10.8.6 CQP HRD Mode Encoding

The application can configure an AVC encoder to work in CQP rate control mode with HRD model parameters. oneVPL will place HRD information to SPS/VUI and choose the appropriate profile/level. It's the responsibility of the application to provide per-frame QP, track HRD conformance, and insert required SEI messages to the bitstream.

The following example shows how to enable CQP HRD mode. The application should set *RateControlMethod* to CQP, *mfxExtCodingOption::VuiNalHrdParameters* to ON, *mfxExtCodingOption::NalHrdConformance* to OFF, and set rate control parameters similar to CBR or VBR modes (instead of QPI, QPP, and QPB). oneVPL will choose CBR or VBR HRD mode based on the MaxKbps parameter. If MaxKbps is set to zero, oneVPL will use CBR HRD model (write `cbr_flag = 1` to VUI), otherwise the VBR model will be used (and `cbr_flag = 0` is written to VUI).

Note: For CQP, if implementation does not support individual QPI, QPP and QPB parameters, then QPI parameter should be used as a QP parameter across all frames.

```

1  mfxExtCodingOption option, *option_array;
2
3  /* configure mfxExtCodingOption */
4  memset(&option, 0, sizeof(option));
5  option.Header.BufferId      = MFX_EXTBUFF_CODING_OPTION;
6  option.Header.BufferSz     = sizeof(option);
7  option.VuiNalHrdParameters = MFX_CODINGOPTION_ON;
8  option.NalHrdConformance   = MFX_CODINGOPTION_OFF;
9
10 /* configure mfxVideoParam */
11 mfxVideoParam param;
12
13 // ...
14
15 param.mfx.RateControlMethod      = MFX_RATECONTROL_CQP;
16 param.mfx.FrameInfo.FrameRateExtN = valid_non_zero_value;
17 param.mfx.FrameInfo.FrameRateExtD = valid_non_zero_value;
18 param.mfx.BufferSizeInKB        = valid_non_zero_value;
19 param.mfx.InitialDelayInKB      = valid_non_zero_value;
20 param.mfx.TargetKbps             = valid_non_zero_value;
21
22 if (write_cbr_flag == 1)
23     param.mfx.MaxKbps = 0;
24 else /* write_cbr_flag = 0 */
25     param.mfx.MaxKbps = valid_non_zero_value;
26
27 param.NumExtParam = 1;
28 option_array      = &option;
29 param.ExtParam    = (mfxExtBuffer **)&option_array;
30
31 /* encoder initialization */
32 mfxStatus sts;
33 sts = MFXVideoENCODE_Init(session, &param);
34
35 // ...
36
37 /* encoding */

```

(continues on next page)

(continued from previous page)

```

38 mfxEncodeCtrl ctrl;
39 memset(&ctrl,0,sizeof(ctrl));
40 ctrl.QP = frame_qp;
41
42 sts=MFXVideoENCODE_EncodeFrameAsync(session,&ctrl,surface2,bits,&syncp);

```

10.9 Glossary

The oneVPL API and documentation uses a standard set of acronyms and terms. This section describes these conventions.

- *Acronyms and Terms*
- *Video Formats*
- *Color Formats*

10.9.1 Acronyms and Terms

AVC Advanced video codec (same as H.264 and MPEG-4, part 10).

BRC Bit rate control.

CQP Constant quantization parameter.

DRM Digital rights management.

DXVA2 Microsoft DirectX* Video Acceleration standard 2.0.

GOP Group of pictures. In video coding, a group of frames in a specific order. In the H.264 standard, a group of I-frames, B-frames and P-frames.

GPB Generalized P/B picture. B-picture, containing only forward references in both L0 and L1.

H.264 Video coding standard. See ISO*/IEC* 14496-10 and ITU-T* H.264, MPEG-4 Part 10, Advanced Video Coding, May 2005.

HDR High dynamic range.

HRD Hypothetical reference decoder, a term used in the H.264 specification.

IDR Instantaneous decoding fresh picture, a term used in the H.264 specification.

LA Look ahead. Special encoding mode where encoder performs pre-analysis of several frames before actual encoding starts.

MCTF Motion compensated temporal filter. Special type of noise reduction filter which utilizes motion to improve efficiency of video denoising.

NAL Network abstraction layer.

PPS Picture parameter set.

QP Quantization parameter.

SEI Supplemental enhancement information.

SPS Sequence parameter set.

VA API Video acceleration API.

VBR Variable bit rate.

VBV Video buffering verifier.

Video memory Memory used by a hardware acceleration device, also known as GPU, to hold frame and other types of video data.

VUI Video usability information.

10.9.2 Video Formats

MPEG Moving Picture Experts Group video file.

MPEG-2 Moving Picture Experts Group video file. See ISO/IEC 13818-2 and ITU-T H.262, MPEG-2 Part 2, Information Technology- Generic Coding of Moving Pictures and Associate Audio Information: Video, 2000.

NV12 YUV 4:2:0 video format, 12 bits per pixel.

NV16 YUV 4:2:2 video format, 16 bits per pixel.

P010 YUV 4:2:0 video format, extends NV12, 10 bits per pixel.

P210 YUV 4:2:2 video format, 10 bits per pixel.

UYVY YUV 4:2:2 video format, 16 bits per pixel.

VC-1 Video coding format. See SMPTE* 421M, SMPTE Standard for Television: VC-1 Compressed Video Bitstream Format and Decoding Process, August 2005.

10.9.3 Color Formats

I010 Color format for raw video frames, extends IYUV/I420 for 10 bit.

IYUV A color format for raw video frames, also known as I420.

RGB32 Thirty-two-bit RGB color format.

RGB4 Thirty-two-bit RGB color format. Also known as RGB32.

YUY2 A color format for raw video frames.

YV12 A color format for raw video frames, similar to IYUV with U and V reversed.

10.10 Deprecated API

The following is a list of deprecated interfaces, starting from API version 2.0.

Table 26: Deprecated API

API	Deprecated in API Version	Removed in API Version	Alternatives	Behaviour change of deprecated API
<i>MFxInit()</i>	2.3		<i>MFxLoad()</i> + <i>MFxCreateSession()</i>	API may return <i>MFx_ERR_NOT_IMPLEMENTED</i> status
<i>MFxInitEx()</i>	2.3		<i>MFxLoad()</i> + <i>MFxCreateSession()</i>	API may return <i>MFx_ERR_NOT_IMPLEMENTED</i> status
<i>mfxExtVPPDenoise</i>	2.5		Use <i>mfxExtVPPDenoise2</i>	No change
MFx_FOURCC_RGB3	2.0		Use <i>MFx_FOURCC_RGB4</i>	No change
<i>mfxExtCodingOption3::EndOfSequence</i>	2.0		Flag is ignored	No change
<i>mfxExtCodingOption3::EndOfStream</i>	2.0		Flag is ignored	No change
<i>mfxExtCodingOption3::ExtBrcAdaptiveLTR</i>	2.0		Use <i>mfxExtCodingOption3::AdaptiveLTR</i>	No change
MFx_EXTBUFF_VPP_SCENE2CHANGE	2.0		Ignored	No change
<i>mfxExtVppAuxData::SpatialComplexity</i>	2.0		Field is not filled by the library	No change
<i>mfxExtVppAuxData::TemporalComplexity</i>	2.0		Field is not filled by the library	No change
<i>mfxExtVppAuxData::SceneChangeRate</i>	2.0		Field is not filled by the library	No change

10.11 Change Log

This section describes the API evolution from version to version.

- *Version 2.8*
- *Version 2.7*
- *Version 2.6*
- *Version 2.5*
- *Version 2.4*
- *Version 2.3*

10.11.1 Version 2.8

New in this release:

- Introduced `MFX_FOURCC_ABGR16F` FourCC for 16-bit float point (per channel) 4:4:4 ABGR format.
- Clarified the `mfExtMasteringDisplayColourVolume::DisplayPrimariesX`, `mfExtMasteringDisplayColourVolume::DisplayPrimariesY` for the video processing usage.
- Added `MFX_CONTENT_NOISY_VIDEO` in `ContentInfo` definition.
- Added Camera Processing API for Camera RAW data.
- Introduced hint to disable external video frames caching for GPU copy.
- Clarified usage of `mfExtMasteringDisplayColourVolume::InsertPayloadToggle` and `mfExtContentLightLevelInfo::InsertPayloadToggle` during decode operations.
- Fixed multiple spelling errors.
- Experimental API: introduced `mfExtMBQP::Pitch` value for QP map defined in `mfExtMBQP`.
- Clarified when `MFXEnumImplementations()` may be called for implementation capabilities query.
- Added table with filenames included in the dispatcher's search process.

Bug Fixes:

- Fixed *Experimental API table* to note that `mfExtRefListCtrl` and `MFX_EXTBUFF_UNIVERSAL_REFLIST_CTRL` were moved to production in version 2.8.

10.11.2 Version 2.7

New in this release:

- `mfExtVppAuxData::RepeatedFrame` flag is actual again and returned back from deprecation state.
- Clarified GPU Copy control behavior.
- Introduced `MFX_FOURCC_XYUV` FourCC for non-alpha packed 4:4:4 format.
- Notice added to the `mfFrameSurfaceInterface::OnComplete` to clarify when library can call this callback.
- New product names for platforms:
 - Code name Alder Lake N.
- Annotated missed aliases `mfExtHEVCRefListCtrl`, `mfExtHEVCRefLists`, `mfExtHEVCTemporalLayers`.
- New dispatcher's config properties:
 - Pass through extension buffer to `mfInitializationParam`.
 - Select host or device responsible for the memory copy between host and device.
- Refined description of struct `mfExtMasteringDisplayColourVolume` and `mfExtContentLightLevelInfo` for HDR SEI decoder usage.
- Experimental API: introduced interface to get statistics after encode.

Bug Fixes:

- Fixed missprint in the `mfExtDeviceAffinityMask` description.
- `MFXVideoENCODE_Query` description fixed for query mode 1.

10.11.3 Version 2.6

New in this release:

- New development practice to treat some new API features as experimental was introduced. All new experimental API is wrapped with ONE_EXPERIMENTAL macro.
- Experimental API: introduced MFX_HANDLE_PXP_CONTEXT to support protected content.
- Experimental API: introduced CPUEncToolsProcessing hint to run adaptive encoding tools on CPU.
- Experimental API: extended device ID reporting to cover multi-adapter cases.
- Experimental API: introduced common alias for mfxExtAVCRefListCtrl
- Experimental API: mfxExtDecodeErrorReport ErrorTypes enum extended with new JPEG/MJPEG decode error report.
- Clarified LowPower flag meaning.
- Described that mfxExtThreadsParam can be attached to mfxInitializationParam during session initialization.
- Refined description of the MFXVideoDECODE_VPP_DecodeFrameAsync function.
- New dispatcher's config filter property: MediaAdapterType.
- Marked all deprecated fields as MFX_DEPRECATED.
- Introduced priority loading option for custom libraries.
- Clarified AV1 encoder behavior about writing of IVF headers.
- Removed outdated note about loading priority of Intel® Media Software Development Kit. For loading details see *oneVPL implementation on Intel® platforms with Xe architecture and Intel® Media Software Development Kit Coexistence*.
- Spelled out mfxVariant type usage for strings.
- New product names for platforms:
 - Code name DG2,
 - Code name ATS-M.

10.11.4 Version 2.5

New in this release:

- Added mfxMediaAdapterType to capability reporting.
- Added surface pool interface.
- Helper macro definition to simplify filter properties set up process for dispatcher.
- Added mfxExtAV1BitstreamParam, mfxExtAV1ResolutionParam and mfxExtAV1TileParam for AV1e.
- Added MFX_RESOURCE_VA_SURFACE_PTR and MFX_RESOURCE_VA_BUFFER_PTR enumerators.
- Clarified HEVC Main 10 Still Picture Profile configuration.
- External Buffer ID of mfxExtVideoSignalInfo and mfxExtMasteringDisplayColourVolume for video processing.
- New MFX_WRN_ALLOC_TIMEOUT_EXPIRED return status. Indicates that all surfaces are currently in use and timeout set by mfxExtAllocationHints for allocation of new surfaces through functions GetSurfaceForXXX expired.

- Introduced universal temporal layering structure.
- Added MFX_RESOURCE_VA_SURFACE_PTR and MFX_RESOURCE_VA_BUFFER_PTR enumerators.
- Introduced segmentation interface for AV1e, including ext-buffers and enums.
- Introduced planar I422 and I210 FourCC codes.

Bug Fixes:

- Dispatcher: Removed /etc/ld.so.cache from oneVPL search order.
- mfxSurfaceArray: CDECL attribute added to the member-functions.

Deprecated:

- mfxExtVPPDenoise extension buffer.

10.11.5 Version 2.4

- Added ability to retrieve path to the shared library with the implementation.
- Added 3DLUT (Three-Dimensional Look Up Table) filter in VPP.
- Added mfxGUID structure to specify Globally Unique Identifiers (GUIDs).
- Added QueryInterface function to mfxFrameSurfaceInterface.
- Added AdaptiveRef and alias for ExtBrcAdaptiveLTR.
- Added MFX_FOURCC_BGRP FourCC for Planar BGR format.
- Environmental variables to control dispatcher's logger.

10.11.6 Version 2.3

- Encoding in Hyper mode.
- New product names for platforms:
 - Code name Rocket Lake,
 - Code name Alder Lake S,
 - Code name Alder Lake P,
 - Code name for Arctic Sound P.
 - For spec version 2.3.1 MFX_PLATFORM_XEHP_SDV alias was added
- mfx.h header file is added which includes all header files.
- Added deprecation messages (deprecation macro) to the functions MFXInit and MFXInitEx functions definition.

ONEMKL

The oneAPI Math Kernel Library (oneMKL) defines a set of fundamental mathematical routines for use in high-performance computing and other applications. As part of oneAPI, oneMKL is designed to allow execution on a wide variety of computational devices: CPUs, GPUs, FPGAs, and other accelerators. The functionality is subdivided into several domains: dense linear algebra, sparse linear algebra, discrete Fourier transforms, random number generators and vector math.

The general assumptions, design features and requirements for the oneMKL library and host-to-device computational routines will be described in *oneMKL Architecture*. The individual domains and their APIs are described in *oneMKL Domains*. Other design considerations that are not necessarily part of the oneMKL specification but that are worth mentioning will be discussed in *oneMKL Appendix*.

11.1 oneMKL Architecture

The oneMKL element of oneAPI has several general assumptions, requirements and recommendations for all domains contained therein. These will be addressed in this architecture section. In particular, DPC++ allows for a great control over the execution of kernels on the various devices. We discuss the supported execution models of oneMKL APIs in *Execution Model*. A discussion of how data is stored and passed in and out of the APIs is addressed in *Memory Model*. The general structure and design of oneMKL APIs including namespaces and common data types are expressed in *API Design*. The exceptions and error handling are described in *Exceptions and Error Handling*. Finally all the other necessary aspects related to oneMKL architecture can be found in *Other Features* including versioning and discussion of pre and post conditions. Other nonessential, but useful aspects of the oneMKL architecture and design may also be found in the *oneMKL Appendix*.

11.1.1 Execution Model

This section describes the execution environment common to all oneMKL functionality. The execution environment includes how data is provided to computational routines in *Use of Queues*, support for several devices in *Device Usage*, synchronous and asynchronous execution models in *Asynchronous Execution* and *Host Thread Safety*.

Use of Queues

The `sycl::queue` defined in the oneAPI DPC++ specification is used to specify the device and features enabled on that device on which a task will be enqueued. There are two forms of computational routines in oneMKL: class based *Member Functions* and standalone *Non-Member Functions*. As these may interact with the `sycl::queue` in different ways, we provide a section for each one to describe assumptions.

Non-Member Functions

Each oneMKL non-member computational routine takes a `sycl::queue` reference as its first parameter:

```
oneMKL::domain::routine(sycl::queue &q, ...);
```

All computation performed by the routine shall be done on the hardware device(s) associated with this queue, with possible aid from the host, unless otherwise specified. In the case of an ordered queue, all computation shall also be ordered with respect to other kernels as if enqueued on that queue.

A particular oneMKL implementation may not support the execution of a given oneMKL routine on the specified device(s). In this case, the implementation may either perform the computation on the host or throw an exception. See *Exceptions and Error Handling* for the possible exceptions.

Member Functions

oneMKL class-based APIs, such as those in the RNG and DFT domains, require a `sycl::queue` as an argument to the constructor or another setup routine. The execution requirements for computational routines from the previous section also apply to computational class methods.

Device Usage

oneMKL itself does not currently provide any interfaces for controlling device usage: for instance, controlling the number of cores used on the CPU, or the number of execution units on a GPU. However, such functionality may be available by partitioning a `sycl::device` instance into subdevices, when supported by the device.

When given a queue associated with such a subdevice, a oneMKL implementation shall only perform computation on that subdevice.

Asynchronous Execution

The oneMKL API is designed to allow asynchronous execution of computational routines, to facilitate concurrent usage of multiple devices in the system. Each computational routine enqueues work to be performed on the selected device, and may (but is not required to) return before execution completes.

Hence, it is the calling application's responsibility to ensure that any inputs are valid until computation is complete, and likewise to wait for computation completion before reading any outputs. This can be done automatically when using DPC++ buffers, or manually when using Unified Shared Memory (USM) pointers, as described in the sections below.

Unless otherwise specified, asynchronous execution is *allowed*, but not *guaranteed*, by any oneMKL computational routine, and may vary between implementations and/or versions. oneMKL implementations must clearly document whether execution is guaranteed to be asynchronous for each supported routine. Regardless, calling applications shall not launch any oneMKL computational routine with a dependency on a future oneMKL API call, even if this computational routine executes asynchronously (i.e. a oneMKL implementation may assume no antidependencies are present). This guarantee allows oneMKL implementations to reserve resources for execution without risking deadlock.

Synchronization When Using Buffers

`sycl::buffer` objects automatically manage synchronization between kernel launches linked by a data dependency (either read-after-write, write-after-write, or write-after-read).

oneMKL routines are not required to perform any additional synchronization of `sycl::buffer` arguments.

Synchronization When Using USM APIs

When USM pointers are used as input to, or output from, a oneMKL routine, it becomes the calling application's responsibility to manage possible asynchronicity.

To help the calling application, all oneMKL routines with at least one USM pointer argument also take an optional reference to a list of *input events*, of type `std::vector<sycl::event>`, and have a return value of type `sycl::event` representing computation completion:

```
sycl::event mkl::domain::routine(..., std::vector<sycl::event> &in_events = {});
```

The routine shall ensure that all input events (if the list is present and non-empty) have occurred before any USM pointers are accessed. Likewise, the routine's output event shall not be complete until the routine has finished accessing all USM pointer arguments.

For class methods, "argument" includes any USM pointers previously provided to the object via the class constructor or other class methods.

Host Thread Safety

All oneMKL member and non-member functions shall be *host thread safe*. That is, they may be safely called simultaneously from concurrent host threads. However, oneMKL objects in class-based APIs may not be shared between concurrent host threads unless otherwise specified.

11.1.2 Memory Model

The oneMKL memory model shall follow directly from the oneAPI memory model. Mainly, oneMKL shall support two modes of encapsulating data for consumption on the device: the buffer memory abstraction model and the pointer-based memory model using Unified Shared Memory (USM). These two paradigms shall also support both synchronous and asynchronous execution models as described in *Asynchronous Execution*.

The Buffer Memory Model

The SYCL 1.2.1 specification defines the buffer container templated on the provided data type which encapsulates the data in a SYCL application across both host and devices. It provides the concept of accessors as the mechanism to access the buffer data with different modes to read and or write into that data. These accessors allow SYCL to create and manage the data dependencies in the SYCL graph that order the kernel executions. With the buffer model, all data movement is handled by the SYCL runtime supporting both synchronous and asynchronous execution.

oneMKL provides APIs where buffers (in particular 1D buffers, `sycl::buffer<T, 1>`) contain the memory for all non scalar input and output data arguments. See *Synchronization When Using Buffers* for details on how oneMKL routines manage any data dependencies with buffer arguments. Any higher dimensional buffer must be converted to a 1D buffer prior to use in oneMKL APIs, e.g., via `buffer::reinterpret`.

Unified Shared Memory Model

While the buffer model is powerful and elegantly expresses data dependencies, it can be a burden for programmers to replace all pointers and arrays by buffers in their C++ applications. DPC++ also provides pointer-based addressing for device-accessible data, using the Unified Shared Memory (USM) model. Correspondingly, oneMKL provides USM APIs in which non-scalar input and output data arguments are passed by USM pointer.

USM devices and system configurations vary in their ability to share data between devices and between a device and the host. oneMKL implementations may only assume that user-provided USM pointers are accessible by the device associated with the user-provided queue. In particular, an implementation must not assume that USM pointers can be accessed by any other device, or by the host, without querying the DPC++ runtime. An implementation must accept any device-accessible USM pointer regardless of how it was created (`sycl::malloc_device`, `sycl::malloc_shared`, etc.).

Unlike buffers, USM pointers cannot automatically manage data dependencies between kernels. Users may use in-order queues to ensure ordered execution, or explicitly manage dependencies with `sycl::event` objects. To support the second use case, oneMKL USM APIs accept input events (prerequisites before computation can begin) and return an output event (indicating computation is complete). See *Synchronization When Using USM APIs* for details.

11.1.3 API Design

This section discusses the general features of oneMKL API design. In particular, it covers the use of namespaces and data types from C++, from DPC++ and new ones introduced for oneMKL APIs.

oneMKL namespaces

The oneMKL library uses C++ namespaces to organize routines by mathematical domain. All oneMKL objects and routines shall be contained within the `oneapi::mkl` base namespace. The individual oneMKL domains use a secondary namespace layer as follows:

names-pace	oneMKL domain or content
<code>oneapi::mkl</code>	oneMKL base namespace, contains general oneMKL data types, objects, exceptions and routines
<code>oneapi::mkl::blas</code>	Basic linear algebra routines from BLAS and BLAS like extensions. The <code>oneapi::mkl::blas</code> namespace should contain two namespaces <code>column_major</code> and <code>row_major</code> to support both matrix layouts. See BLAS Routines
<code>oneapi::mkl::lapack</code>	Advanced linear algebra routines from LAPACK and LAPACK like extensions. See LAPACK Routines
<code>oneapi::mkl::sparse</code>	Sparse linear algebra routines from Sparse BLAS and Sparse Solvers. See Sparse Linear Algebra
<code>oneapi::mkl::dft</code>	Discrete and fast Fourier transformations. See Discrete Fourier Transform Functions
<code>oneapi::mkl::rng</code>	Random number generator routines. See Random Number Generators
<code>oneapi::mkl::vector</code>	Vector mathematics routines, e.g. trigonometric, exponential functions acting on elements of a vector. See Vector Math

Note: Inside each oneMKL domain, there are many routines, classes, enums and objects defined which constitute the breadth and scope of that oneMKL domain. It is permitted for a library implementation of the oneMKL specification to implement either all, one or more than one of the domains in oneMKL. However, within an implementation of a specific domain, all relevant routines, classes, enums and objects (including those relevant enums and objects which live outside a particular domain in the general `oneapi::mkl` namespace must be both declared and defined in the library so that an application that uses that domain could build and link against that library implementation successfully.

It is however acceptable to throw the runtime exception `oneapi::mkl::unimplemented` inside of the routines or class member functions in that domain that have not been fully implemented. For instance, a library may choose to implement the oneMKL BLAS functionality and in particular may choose to implement only the `gemm` api for their library, in which case they must also include all the other blas namespaced routines and throw the `oneapi::mkl::unimplemented` exception inside all the others.

In such a case, the implemented routines in such a library should be communicated clearly and easily understood by users of that library.

Standard C++ datatype usage

oneMKL uses C++ STL data types for scalars where applicable:

- Integer scalars are C++ fixed-size integer types (`std::intN_t`, `std::uintN_t`).
- Complex numbers are represented by C++ `std::complex` types.

In general, scalar integer arguments to oneMKL routines are 64-bit integers (`std::int64_t` or `std::uint64_t`). Integer vectors and matrices may have varying bit widths, defined on a per-routine basis.

DPC++ datatype usage

oneMKL uses the following DPC++ data types:

- SYCL queue `sycl::queue` for scheduling kernels on a SYCL device. See *Use of Queues* for more details.
- SYCL buffer `sycl::buffer` for buffer-based memory access. See *The Buffer Memory Model* for more details.
- Unified Shared Memory (USM) for pointer-based memory access. See *Unified Shared Memory Model* for more details.
- SYCL event `sycl::event` for output event synchronization in oneMKL routines with USM pointers. See *Synchronization When Using USM APIs* for more details.
- Vector of SYCL events `std::vector<sycl::event>` for input events synchronization in oneMKL routines with USM pointers. See *Synchronization When Using USM APIs* for more details.

Note: The class `sycl::vector_class` has been removed from SYCL 2020 and the standard class `std::vector` should be used instead for vector of SYCL events in oneMKL routines with USM pointers

oneMKL defined datatypes

oneMKL dense and sparse linear algebra routines use scoped enum types as type-safe replacements for the traditional character arguments used in C/Fortran implementations of BLAS and LAPACK. These types all belong to the `oneapi::mkl` namespace.

Each enumeration value comes with two names: A single-character name (the traditional BLAS/LAPACK character) and a longer, more descriptive name. The two names are exactly equivalent and may be used interchangeably.

transpose

The `transpose` type specifies whether an input matrix should be transposed and/or conjugated. It can take the following values:

Short Name	Long Name	Description
<code>transpose::t</code>	<code>transpose::nontrans</code>	Do not transpose or conjugate the matrix.
<code>transpose::tT</code>	<code>transpose::trans</code>	Transpose the matrix (without complex conjugation).
<code>transpose::tC</code>	<code>transpose::conjtrans</code>	Perform Hermitian transpose (transpose and conjugate). Is the same as <code>transpose::trans</code> for real matrices.

uplo

The `uplo` type specifies whether the lower or upper triangle of a triangular, symmetric, or Hermitian matrix should be accessed. It can take the following values:

Short Name	Long Name	Description
<code>uplo::U</code>	<code>uplo::upper</code>	Access the upper triangle of the matrix.
<code>uplo::L</code>	<code>uplo::lower</code>	Access the lower triangle of the matrix.

In both cases, elements that are not in the selected triangle are not accessed or updated.

diag

The `diag` type specifies the values on the diagonal of a triangular matrix. It can take the following values:

Short Name	Long Name	Description
<code>diag::N</code>	<code>diag::nonunit</code>	The matrix is not unit triangular. The diagonal entries are stored with the matrix data.
<code>diag::U</code>	<code>diag::unit</code>	The matrix is unit triangular (the diagonal entries are all 1's). The diagonal entries in the matrix data are not accessed.

side

The `side` type specifies the order of matrix multiplication when one matrix has a special form (triangular, symmetric, or Hermitian):

Short Name	Long Name	Description
<code>side::L</code>	<code>side::left</code>	The special form matrix is on the left in the multiplication.
<code>side::R</code>	<code>side::right</code>	The special form matrix is on the right in the multiplication.

offset

The `offset` type specifies whether the offset to apply to an output matrix is a fix offset, column offset or row offset. It can take the following values

Short Name	Long Name	Description
<code>offset::fix</code>	<code>offset::fix</code>	The offset to apply to the output matrix is fix, all the inputs in the <code>C_offset</code> matrix has the same value given by the first element in the <code>co</code> array.
<code>offset::column</code>	<code>offset::column</code>	The offset to apply to the output matrix is a column offset, that is to say all the columns in the <code>C_offset</code> matrix are the same and given by the elements in the <code>co</code> array.
<code>offset::row</code>	<code>offset::row</code>	The offset to apply to the output matrix is a row offset, that is to say all the rows in the <code>C_offset</code> matrix are the same and given by the elements in the <code>co</code> array.

index_base

The `index_base` type specifies how values in index arrays are interpreted. For instance, a sparse matrix stores nonzero values and the indices that they correspond to. The indices are traditionally provided in one of two forms: *C/C++*-style using zero-based indices, or *Fortran*-style using one-based indices. The `index_base` type can take the following values:

Name	Description
<code>index_base::zero</code>	Index arrays for an input matrix are provided using zero-based (<i>C/C++</i> style) index values. That is, indices start at 0.
<code>index_base::one</code>	Index arrays for an input matrix are provided using one-based (<i>Fortran</i> style) index values. That is, indices start at 1.

layout

The `layout` type specifies how a dense matrix `A` with leading dimension `lda` is stored as one dimensional array in memory. The layouts are traditionally provided in one of two forms: C/C++-style using `row_major` layout, or Fortran-style using `column_major` layout. The `layout` type can take the following values:

Short Name	Long Name	Description
<code>layout::row_major</code>	<code>row_major</code>	For row major layout, the elements of each row of a dense matrix <code>A</code> are contiguous in memory while the elements of each column are at distance <code>lda</code> from the element in the same column and the previous row.
<code>layout::column_major</code>	<code>column_major</code>	For column major layout, the elements of each column of a dense matrix <code>A</code> are contiguous in memory while the elements of each row are at distance <code>lda</code> from the element in the same row and the previous column.

Note: *oneMKL Appendix* may contain other API design decisions or recommendations that may be of use to the general developer of oneMKL, but which may not necessarily be part of the oneMKL specification.

11.1.4 Exceptions and Error Handling

oneMKL error handling relies on the mechanism of C++ exceptions. Should error occur, it will be propagated at the point of a function call where it is caught using standard C++ error handling mechanism.

Exception classification

Exception classification in oneMKL is aligned with C++ Standard Library classification. oneMKL introduces class that defines the base class in the hierarchy of oneMKL exception classes. All oneMKL routines throw exceptions inherited from this base class. In the hierarchy of oneMKL exceptions, `oneapi::mkl::exception` is the base class inherited from `std::exception` class. All other oneMKL exception classes are derived from this base class.

This specification does not require implementations to perform error-checking. However, if an implementation does provide error-checking, it shall use the following exception classes. Additional implementation-specific exception classes can be used for exceptional conditions not fitting any of these classes.

Common exceptions

Exception class	Description
<code>oneapi::mkl::exception</code>	Reports general unspecified problem
<code>oneapi::mkl::unsupported_device</code>	Reports a problem when the routine is not supported on a specific device
<code>oneapi::mkl::host_bad_alloc</code>	Reports a problem that occurred during memory allocation on the host
<code>oneapi::mkl::device_bad_alloc</code>	Reports a problem that occurred during memory allocation on a specific device
<code>oneapi::mkl::unimplemented</code>	Reports a problem when a specific routine has not been implemented for the specified parameters
<code>oneapi::mkl::invalid_argument</code>	Reports problem when arguments to the routine were rejected
<code>oneapi::mkl::uninitialized</code>	Reports problem when a handle (descriptor) has not been initialized
<code>oneapi::mkl::computation_error</code>	Reports any computation errors that have occurred inside a oneMKL routine
<code>oneapi::mkl::batch_error</code>	Reports errors that have occurred inside a batch oneMKL routine

LAPACK specific exceptions

Exception class	Description
<code>oneapi::mkl::lapack::exception</code>	Base class for all LAPACK exceptions providing access to info code familiar to users of conventional LAPACK API. All LAPACK related exceptions can be handled with catch block for this class.
<code>oneapi::mkl::lapack::invalid_argument</code>	Reports errors when arguments provided to the LAPACK subroutine are inconsistent or do not match expected values. Class extends base <code>oneapi::mkl::invalid_argument</code> with ability to access conventional status info code.
<code>oneapi::mkl::lapack::computation_error</code>	Reports computation errors that have occurred during call to LAPACK subroutine. Class extends base <code>oneapi::mkl::computation_error</code> with ability to access conventional status info code familiar to LAPACK users.
<code>oneapi::mkl::lapack::batch_error</code>	Reports errors that have occurred during batch LAPACK computations. Class extends base <code>oneapi::mkl::batch_error</code> with ability to access individual exception objects for each of the issues observed in a batch and an info code. The info code contains the number of errors that occurred in a batch. Positions of problems in a supplied batch that experienced issues during computations can be retrieved with <code>ids()</code> method, and list of particular exceptions can be obtained with <code>exceptions()</code> method of the exception object. Possible exceptions for a batch are documented for corresponding non-batch API.

11.1.5 Other Features

This section covers all other features in the design of oneMKL architecture.

Current Version of this oneMKL Specification

This is the oneMKL specification which is part of the oneAPI specification version 1.0.0.

Pre/Post Condition Checking

The individual oneMKL computational routines will define any preconditions and postconditions and will define in this specification any specific checks or verifications that should be enabled for all implementations.

11.2 oneMKL Domains

This section describes the Data Parallel C++ (DPC++) interface.

11.2.1 Dense Linear Algebra

This section contains information about dense linear algebra routines:

Matrix Storage provides information about dense matrix and vector storage formats that are used by oneMKL *BLAS Routines* and *LAPACK Routines*.

BLAS Routines provides vector, matrix-vector, and matrix-matrix routines for dense matrices and vector operations.

LAPACK Routines provides more complex dense linear algebra routines, e.g., matrix factorization, solving dense systems of linear equations, least square problems, eigenvalue and singular value problems, and performing a number of related computational tasks.

Matrix Storage

The oneMKL BLAS and LAPACK routines for DPC++ use several matrix and vector storage formats. These are the same formats used in traditional Fortran BLAS/LAPACK.

General Matrix

A general matrix A of m rows and n columns with leading dimension lda is represented as a one dimensional array a of size of at least $lda * n$ if column major layout is used and at least $lda * m$ if row major layout is used. Before entry in any BLAS function using a general matrix, the leading m by n part of the array a must contain the matrix A . For column (respectively row) major layout, the elements of each column (respectively row) are contiguous in memory while the elements of each row (respectively column) are at distance lda from the element in the same row (respectively column) and the previous column (respectively row).

Visually, the matrix

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} & \dots & A_{1n} \\ A_{21} & A_{22} & A_{23} & \dots & A_{2n} \\ A_{31} & A_{32} & A_{33} & \dots & A_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ A_{m1} & A_{m2} & A_{m3} & \dots & A_{mn} \end{bmatrix}$$

is stored in memory as an array

- For column major layout,

$$a = \underbrace{[A_{11}, A_{21}, A_{31}, \dots, A_{m1}, *, \dots, *]}_{lda} \underbrace{[A_{12}, A_{22}, A_{32}, \dots, A_{m2}, *, \dots, *]}_{lda} \dots \underbrace{[A_{1n}, A_{2n}, A_{3n}, \dots, A_{mn}, *, \dots, *]}_{lda}$$

$lda \times n$

- For row major layout,

$$a = \underbrace{[A_{11}, A_{12}, A_{13}, \dots, A_{1n}, *, \dots, *]}_{lda} \underbrace{[A_{21}, A_{22}, A_{23}, \dots, A_{2n}, *, \dots, *]}_{lda} \dots \underbrace{[A_{m1}, A_{m2}, A_{m3}, \dots, A_{mn}, *, \dots, *]}_{lda}$$

$m \times lda$

Triangular Matrix

A triangular matrix A of n rows and n columns with leading dimension lda is represented as a one dimensional array a , of a size of at least $lda * n$. When column (respectively row) major layout is used, the elements of each column (respectively row) are contiguous in memory while the elements of each row (respectively column) are at distance lda from the element in the same row (respectively column) and the previous column (respectively row).

Before entry in any BLAS function using a triangular matrix,

- If `upper_lower = uplo::upper`, the leading n by n upper triangular part of the array a must contain the upper triangular part of the matrix A . The strictly lower triangular part of the array a is not referenced. In other words, the matrix

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} & \dots & A_{1n} \\ * & A_{22} & A_{23} & \dots & A_{2n} \\ * & * & A_{33} & \dots & A_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ * & * & * & \dots & A_{nn} \end{bmatrix}$$

is stored in memory as the array

- For column major layout,

$$a = \underbrace{[A_{11}, *, \dots, *]}_{lda} \underbrace{[A_{12}, A_{22}, *, \dots, *]}_{lda} \dots \underbrace{[A_{1n}, A_{2n}, A_{3n}, \dots, A_{nn}, *, \dots, *]}_{lda}$$

$lda \times n$

- For row major layout,

$$a = \underbrace{[A_{11}, A_{12}, A_{13}, \dots, A_{1n}, *, \dots, *]}_{lda} \underbrace{[A_{22}, A_{23}, \dots, A_{2n}, *, \dots, *]}_{lda} \dots \underbrace{[*, \dots, *, A_{nn}, *, \dots, *]}_{lda}$$

$lda \times n$

- If `upper_lower = uplo::lower`, the leading n by n lower triangular part of the array a must contain the lower triangular part of the matrix A . The strictly upper triangular part of the array a is not referenced. That is, the matrix

$$A = \begin{bmatrix} A_{11} & * & * & \dots & * \\ A_{21} & A_{22} & * & \dots & * \\ A_{31} & A_{32} & A_{33} & \dots & * \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ A_{n1} & A_{n2} & A_{n3} & \dots & A_{nn} \end{bmatrix}$$

is stored in memory as the array

- For column major layout,

$$a = \underbrace{[A_{11}, A_{21}, A_{31}, \dots, A_{n1}, *, \dots, *, *, A_{22}, A_{32}, \dots, A_{n2}, *, \dots, *, \dots, *, \dots, *, A_{nn}, *, \dots, *]}_{lda \times n}$$

- For row major layout,

$$a = \underbrace{[A_{11}, *, \dots, *, A_{21}, A_{22}, *, \dots, *, \dots, A_{n1}, A_{n2}, A_{n3}, \dots, A_{nn}, *, \dots, *]}_{lda \times n}$$

Band Matrix

A general band matrix A of m rows and n columns with k_l sub-diagonals, k_u super-diagonals, and leading dimension lda is represented as a one dimensional array a of a size of at least $lda * n$ (respectively $lda * m$) if column (respectively row) major layout is used.

Before entry in any BLAS function using a general band matrix, the leading $(k_l + k_u + 1)$ by n (respectively m) part of the array a must contain the matrix A . This matrix must be supplied column-by-column (respectively row-by-row), with the main diagonal of the matrix in row k_u (respectively k_l) of the array (0-based indexing), the first super-diagonal starting at position 1 (respectively 0) in row $(k_u - 1)$ (respectively column $(k_l + 1)$), the first sub-diagonal starting at position 0 (respectively 1) in row $(k_u + 1)$ (respectively column $(k_l - 1)$), and so on. Elements in the array a that do not correspond to elements in the band matrix (such as the top left k_u by k_u triangle) are not referenced.

Visually, the matrix A

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} & \dots & A_{1,ku+1} & * & \dots & \dots & \dots & \dots & \dots & * \\ A_{21} & A_{22} & A_{23} & A_{24} & \dots & A_{2,ku+2} & * & \dots & \dots & \dots & \dots & * \\ A_{31} & A_{32} & A_{33} & A_{34} & A_{35} & \dots & A_{3,ku+3} & * & \dots & \dots & \dots & * \\ \vdots & A_{42} & A_{43} & \ddots & \ddots & \ddots & \ddots & \ddots & * & \dots & \dots & \vdots \\ A_{kl+1,1} & \vdots & A_{53} & \ddots & \ddots & \ddots & \ddots & \ddots & * & \dots & \dots & \vdots \\ * & A_{kl+2,2} & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & * & A_{kl+3,3} & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & * \\ \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \vdots & * & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & A_{n-ku,n} \\ \vdots & \vdots & \vdots & * & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \vdots & * & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & A_{m-2,n} \\ \vdots & \vdots & \vdots & \vdots & \vdots & * & \ddots & \ddots & \ddots & \ddots & \ddots & A_{m-1,n} \\ * & * & * & \dots & \dots & \dots & * & A_{m,m-kl} & \dots & A_{m,n-2} & A_{m,n-1} & A_{m,n} \end{bmatrix}$$

is stored in memory as an array

- For column major layout,

$$a = \underbrace{[* , \dots , *]}_{ku} \underbrace{, A_{11}, A_{12}, \dots, A_{\min(kl+1,m),1}, * , \dots , * , * , \dots , *}_{ku-1} \underbrace{, A_{\max(1,2-ku),2}, \dots, A_{\min(kl+2,m),2}, * , \dots , * , \dots , *}_{lda} \underbrace{, * , \dots , *}_{\max(0,ku-n+1)} \underbrace{, A_{\max(1,n-ku),n}, \dots , *}_{lda}$$

- For row major layout,

$$a = \underbrace{[* , \dots , *]}_{kl} \underbrace{, A_{11}, A_{12}, \dots, A_{1,\min(ku+1,n)}, * , \dots , * , * , \dots , *}_{kl-1} \underbrace{, A_{2,\max(1,2-kl)}, \dots, A_{2,\min(ku+2,n)}, * , \dots , * , \dots , *}_{lda} \underbrace{, * , \dots , *}_{\max(0,kl-m+1)} \underbrace{, A_{m,\max(1,m-kl)}, \dots , *}_{lda}$$

The following program segment transfers a band matrix from conventional full matrix storage (variable `matrix`, with leading dimension `ldm`) to band storage (variable `a`, with leading dimension `lda`):

- Using matrices stored with column major layout,

```
for (j = 0; j < n; j++) {
    k = ku - j;
    for (i = max(0, j - ku); i < min(m, j + kl + 1); i++) {
        a[(k + i) + j * lda] = matrix[i + j * ldm];
    }
}
```

- Using matrices stored with row major layout,

```
for (i = 0; i < m; i++) {
    k = kl - i;
    for (j = max(0, i - kl); j < min(n, i + ku + 1); j++) {
        a[(k + j) + i * lda] = matrix[j + i * ldm];
    }
}
```

Triangular Band Matrix

A triangular band matrix A of n rows and n columns with k sub/super-diagonals and leading dimension `lda` is represented as a one dimensional array `a` of size at least `lda * n`.

Before entry in any BLAS function using a triangular band matrix,

- If `upper_lower = uplo : upper`, the leading $(k + 1)$ by n part of the array `a` must contain the upper triangular band part of the matrix A . When using column major layout, this matrix must be supplied column-by-column (respectively row-by-row) with the main diagonal of the matrix in row (k) (respectively column 0) of the array, the first super-diagonal starting at position 1 (respectively 0) in row ($k - 1$) (respectively column 1), and so on. Elements in the array `a` that do not correspond to elements in the triangular band matrix (such as the top left k by k triangle) are not referenced.

Visually, the matrix

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} & \dots & A_{1,k+1} & * & \dots & \dots & \dots & \dots & * \\ * & A_{22} & A_{23} & A_{24} & \dots & A_{2,k+2} & * & \dots & \dots & \dots & * \\ \vdots & * & A_{33} & A_{34} & A_{35} & \dots & A_{3,k+3} & * & \dots & \dots & * \\ \vdots & \vdots & * & \ddots & \ddots & \ddots & \ddots & \ddots & * & \dots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & * & \vdots \\ \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & * \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & A_{n-k,n} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & A_{n-2,n} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & A_{n-1,n} \\ * & * & * & \dots & \dots & \dots & \dots & \dots & \dots & * & A_{n,n} \end{bmatrix}$$

is stored as an array

- For column major layout,

$$a = \underbrace{[* \dots *]}_{ku} \underbrace{[A_{11}, * \dots *]}_{lda} \underbrace{[* \dots *]}_{ku-1} \underbrace{[A_{max(1,2-k),2}, \dots, A_{2,2}, * \dots *]}_{lda} \underbrace{[* \dots *]}_{\max(0,k-n+1)} \underbrace{[A_{max(1,n-k),n}, \dots, A_{n,n}, * \dots *]}_{lda}$$

$lda \times n$

- For row major layout,

$$a = \underbrace{[A_{11}, A_{21}, \dots, A_{min(k+1,n),1}, * \dots *]}_{lda} \underbrace{[A_{2,2}, \dots, A_{min(k+2,n),2}, * \dots *]}_{lda} \underbrace{[\dots, A_{n,n}, * \dots *]}_{lda}$$

$lda \times n$

The following program segment transfers a band matrix from conventional full matrix storage (variable `matrix`, with leading dimension `ldm`) to band storage (variable `a`, with leading dimension `lda`):

- Using matrices stored with column major layout,

```
for (j = 0; j < n; j++) {
    m = k - j;
    for (i = max(0, j - k); i <= j; i++) {
        a[(m + i) + j * lda] = matrix[i + j * ldm];
    }
}
```

- Using matrices stored with row major layout,

```
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < min(n, i + k + 1); j++) {
        a[(m + j) + i * lda] = matrix[j + i * ldm];
    }
}
```

- If `upper_lower = uplo::lower`, the leading $(k + 1)$ by n part of the array `a` must contain the upper triangular band part of the matrix `A`. This matrix must be supplied column-by-column with the main diagonal of the matrix in row 0 of the array, the first sub-diagonal starting at position 0 in row 1, and so on. Elements in the array `a` that do not correspond to elements in the triangular band matrix (such as the bottom right k by k triangle) are not referenced.

That is, the matrix

$$A = \begin{bmatrix} A_{11} & * & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & * \\ A_{21} & A_{22} & * & \dots & \dots & \dots & \dots & \dots & \dots & \dots & * \\ A_{31} & A_{32} & A_{33} & * & \dots & \dots & \dots & \dots & \dots & \dots & * \\ \vdots & A_{42} & A_{43} & \ddots & \ddots & \dots & \dots & \dots & \dots & \dots & \vdots \\ A_{k+1,1} & \vdots & A_{53} & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ * & A_{k+2,2} & \vdots & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ \vdots & * & A_{k+3,3} & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ \vdots & \vdots & * & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \dots & \dots & \dots & \dots & \vdots \\ * & * & * & \dots & \dots & \dots & * & A_{n,n-k} & \dots & A_{n,n-2} & A_{n,n-1} & A_{n,n}^* \end{bmatrix}$$

is stored as the array

- For column major layout,

$$a = [\underbrace{A_{11}, A_{21}, \dots, A_{\min(k+1, n), 1}}_{lda}, \underbrace{*, \dots, *, A_{2, 2}, \dots, A_{\min(k+2, n), 2}}_{lda}, \dots, \underbrace{A_{n, n}, *, \dots *}_{lda}]$$

$lda \times n$

- For row major layout,

$$a = [\underbrace{*, \dots, *, A_{11}, *, \dots, *, *, \dots, *, A_{\max(1, 2-k), 2}}_{lda}, \dots, \underbrace{*, \dots, *, A_{\max(1, n-k), n}}_{\max(0, k-n+1)}, \dots, \underbrace{A_{n, n}, *, \dots *}_{lda}]$$

$lda \times n$

The following program segment transfers a band matrix from conventional full matrix storage (variable `matrix`, with leading dimension `ldm`) to band storage (variable `a`, with leading dimension `lda`):

- Using matrices stored with column major layout,

```
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
        a[(m + i) + j * lda] = matrix[i + j * ldm];
    }
}
```

- Using matrices stored with row major layout,

```
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i - k); j <= i; j++) {
        a[(m + j) + i * lda] = matrix[j + i * ldm];
    }
}
```

Packed Triangular Matrix

A triangular matrix `A` of `n` rows and `n` columns is represented in packed format as a one dimensional array `a` of size at least $(n*(n + 1))/2$. All elements in the upper or lower part of the matrix `A` are stored contiguously in the array `a`.

Before entry in any BLAS function using a triangular packed matrix,

- If `upper_lower = uplo:upper`, if column (respectively row) major layout is used, the first $(n*(n + 1))/2$ elements in the array `a` must contain the upper triangular part of the matrix `A` packed sequentially, column by column (respectively row by row) so that `a[0]` contains `A11`, `a[1]` and `a[2]` contain `A12` and `A22` (respectively `A13`) respectively, and so on. Hence, the matrix

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} & \dots & A_{1n} \\ * & A_{22} & A_{23} & \dots & A_{2n} \\ * & * & A_{33} & \dots & A_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ * & * & * & \dots & A_{nn} \end{bmatrix}$$

is stored as the array

- For column major layout,

$$a=[A_{11},A_{12},A_{22},A_{13},A_{23},A_{33},\dots,A_{(n-1),n},A_{nn}]$$

- For row major layout,

$$a=[A_{11},A_{12},A_{13},\dots,A_{1n},A_{22},A_{23},\dots,A_{2n},\dots,A_{(n-1),(n-1)},A_{(n-1),n},A_{nn}]$$

- If `upper_lower = uplo::lower`, if column (respectively row) major layout is used, the first $(n*(n + 1))/2$ elements in the array `a` must contain the lower triangular part of the matrix `A` packed sequentially, column by column (row by row) so that `a[0]` contains A_{11} , `a[1]` and `a[2]` contain A_{21} and A_{31} (respectively A_{22}) respectively, and so on. The matrix

$$A = \begin{bmatrix} A_{11} & * & * & \dots & * \\ A_{21} & A_{22} & * & \dots & * \\ A_{31} & A_{32} & A_{33} & \dots & * \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ A_{n1} & A_{n2} & A_{n3} & \dots & A_{nn} \end{bmatrix}$$

is stored as the array

- For column major layout,

$$a=[A_{11},A_{21},A_{31},\dots,A_{n1},A_{22},A_{32},\dots,A_{n2},\dots,A_{(n-1),(n-1)},A_{n,(n-1)},A_{nn}]$$

- For row major layout,

$$a=[A_{11},A_{21},A_{22},A_{31},A_{32},A_{33},\dots,A_{n,(n-1)},A_{nn}]$$

Vector

A vector `X` of `n` elements with increment `incx` is represented as a one dimensional array `x` of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.

Visually, the vector

$$X = (X_1, X_2, X_3, \dots, X_n)$$

is stored in memory as an array

$$x = \underbrace{[\underbrace{X_1, *, \dots, *}_{\text{incx}}, \underbrace{X_2, *, \dots, *}_{\text{incx}}, \dots, \underbrace{X_{n-1}, *, \dots, *}_{\text{incx}}, X_n]}_{1 + (n-1) \times \text{incx}} \quad \text{if } \text{incx} > 0$$

$$x = \underbrace{[X_n, *, \dots, *, \underbrace{X_{n-1}, *, \dots, *}_{|\text{incx}|}, \dots, \underbrace{X_2, *, \dots, *}_{|\text{incx}|}, X_1]}_{1 + (1-n) \times \text{incx}} \quad \text{if } \text{incx} < 0$$

BLAS Routines

oneMKL provides DPC++ interfaces to the Basic Linear Algebra Subprograms (BLAS) routines (Level1, Level2, Level3), as well as several BLAS-like extension routines.

BLAS Level 1 Routines

BLAS Level 1 includes routines which perform vector-vector operations as described in the following table.

Routines	Description
<i>asum</i>	Sum of vector magnitudes
<i>axpy</i>	Scalar-vector product
<i>copy</i>	Copy vector
<i>dot</i>	Dot product
<i>sdsdot</i>	Dot product with double precision
<i>dotc</i>	Dot product conjugated
<i>dotu</i>	Dot product unconjugated
<i>nrm2</i>	Vector 2-norm (Euclidean norm)
<i>rot</i>	Plane rotation of points
<i>rotg</i>	Generate Givens rotation of points
<i>rotm</i>	Modified Givens plane rotation of points
<i>rotmg</i>	Generate modified Givens plane rotation of points
<i>scal</i>	Vector-scalar product
<i>swap</i>	Vector-vector swap
<i>iamax</i>	Index of the maximum absolute value element of a vector
<i>iamin</i>	Index of the minimum absolute value element of a vector

asum

Computes the sum of magnitudes of the vector elements.

Description

The *asum* routine computes the sum of the magnitudes of elements of a real vector, or the sum of magnitudes of the real and imaginary parts of elements of a complex vector:

$$result = \sum_{i=1}^n (|Re(x_i)| + |Im(x_i)|)$$

where *x* is a vector with *n* elements.

asum supports the following precisions for data:

T	Tres
float	float
double	double
std::complex<float>	float
std::complex<double>	double

asum (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void asum(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<Tres,1> &result)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void asum(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<Tres,1> &result)
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

Output Parameters

result Buffer where the scalar result is stored (the sum of magnitudes of the real and imaginary parts of all elements of the vector).

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

asum (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event asum(sycl::queue &queue,
                    std::int64_t n,
                    const T *x,
                    std::int64_t incx,
                    Tres *result,
                    const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event asum(sycl::queue &queue,
                    std::int64_t n,
                    const T *x,
                    std::int64_t incx,
                    Tres *result,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Pointer to input vector **x**. The array holding the vector **x** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

result Pointer to the output matrix where the scalar result is stored (the sum of magnitudes of the real and imaginary parts of all elements of the vector).

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

axpy

Computes a vector-scalar product and adds the result to a vector.

Description

The axpy routines compute a scalar-vector product and add the result to a vector:

$$y \leftarrow \alpha * x + y$$

where:

x and y are vectors of n elements,

alpha is a scalar.

axpy supports the following precisions.

T
half
bfloat16
float
double
std::complex<float>
std::complex<double>

axpy (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void axpy(sycl::queue &queue,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
```

(continues on next page)

(continued from previous page)

```

        std::int64_t incy)
    }

```

```

namespace oneapi::mkl::blas::row_major {
    void axpy(sycl::queue &queue,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

alpha Specifies the scalar alpha.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Buffer holding input vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

Output Parameters

y Buffer holding the updated vector **y**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

axpy (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event axpy(sycl::queue &queue,
                    std::int64_t n,
                    T alpha,
                    const T *x,
                    std::int64_t incx,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event axpy(sycl::queue &queue,
                    std::int64_t n,
                    T alpha,
                    const T *x,
                    std::int64_t incx,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

alpha Specifies the scalar alpha.

x Pointer to the input vector **x**. The array holding the vector **x** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See [Matrix Storage](#) for more details.

incx Stride of vector **x**.

y Pointer to the input vector **y**. The array holding the vector **y** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See [Matrix Storage](#) for more details.

incy Stride of vector **y**.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Pointer to the updated vector y.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

copy

Copies a vector to another vector.

Description

The copy routines copy one vector to another:

$$y \leftarrow x$$

where **x** and **y** are vectors of **n** elements.

copy supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

copy (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void copy(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void copy(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

incy Stride of vector **y**.

Output Parameters

y Buffer holding the updated vector **y**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

copy (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event copy(sycl::queue &queue,
                    std::int64_t n,
                    const T *x,
                    std::int64_t incx,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event copy(sycl::queue &queue,
                    std::int64_t n,
                    const T *x,
                    std::int64_t incx,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Pointer to the input vector **x**. The array holding the vector **x** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

incy Stride of vector **y**.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Pointer to the updated vector **y**.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

dot

Computes the dot product of two real vectors.

Description

The dot routines perform a dot product between two vectors:

$$result = \sum_{i=1}^n X_i Y_i$$

dot supports the following precisions for data.

T	Tres
half	half
bfloat16	bfloat16
float	float
double	double
float	double

Note

For the mixed precision version (inputs are float while result is double), the dot product is computed with double precision.

dot (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void dot(sycl::queue &queue,
            std::int64_t n,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &y,
```

(continues on next page)

(continued from previous page)

```

    std::int64_t incy,
    sycl::buffer<Tres,1> &result)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void dot(sycl::queue &queue,
            std::int64_t n,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &y,
            std::int64_t incy,
            sycl::buffer<Tres,1> &result)
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vectors **x** and **y**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Buffer holding input vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

Output Parameters

result Buffer where the result (a scalar) will be stored.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

dot (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event dot(sycl::queue &queue,
                  std::int64_t n,
                  const T *x,
                  std::int64_t incx,
                  const T *y,
                  std::int64_t incy,
                  Tres *result,
                  const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event dot(sycl::queue &queue,
                  std::int64_t n,
                  const T *x,
                  std::int64_t incx,
                  const T *y,
                  std::int64_t incy,
                  Tres *result,
                  const std::vector<sycl::event> &dependencies = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vectors **x** and **y**.

x Pointer to the input vector **x**. The array holding the vector **x** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Pointer to the input vector **y**. The array holding the vector **y** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

result Pointer to where the result (a scalar) will be stored.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

sdsdot

Computes a vector-vector dot product with double precision.

Description

The sdsdot routines perform a dot product between two vectors with double precision:

$$result = sb + \sum_{i=1}^n X_i Y_i$$

sdsdot (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void sdsdot(sycl::queue &queue,
               std::int64_t n,
               float sb,
               sycl::buffer<float,1> &x,
               std::int64_t incx,
               sycl::buffer<float,1> &y,
               std::int64_t incy,
               sycl::buffer<float,1> &result)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void sdsdot(sycl::queue &queue,
               std::int64_t n,
               float sb,
               sycl::buffer<float,1> &x,
```

(continues on next page)

(continued from previous page)

```

        std::int64_t incx,
        sycl::buffer<float,1> &y,
        std::int64_t incy,
        sycl::buffer<float,1> &result)
    }

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vectors **x** and **y**.

sb Single precision scalar to be added to the dot product.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Buffer holding input vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incxy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

Output Parameters

result Buffer where the result (a scalar) will be stored. If $n < 0$ the result is **sb**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

    std::int64_t incy,
    float *result,
    const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event sdsdot(sycl::queue &queue,
        std::int64_t n,
        float sb,
        const float *x,
        std::int64_t incx,
        const float *y,
        std::int64_t incy,
        float *result,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vectors **x** and **y**.

sb Single precision scalar to be added to the dot product.

x Pointer to the input vector **x**. The array must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Pointer to the input vector **y**. The array must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

result Pointer to where the result (a scalar) will be stored. If $n < 0$ the result is **sb**.

Return Values

Output event to wait on to ensure computation is complete.

dotc

Computes the dot product of two complex vectors, conjugating the first vector.

Description

The dotc routines perform a dot product between two complex vectors, conjugating the first of them:

$$result = \sum_{i=1}^n \overline{X_i} Y_i$$

dotc supports the following precisions for data.

T
std::complex<float>
std::complex<double>

dotc (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void dotc(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &result)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void dotc(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
```

(continues on next page)

(continued from previous page)

```

        std::int64_t incx,
        sycl::buffer<T,1> &y,
        std::int64_t incy,
        sycl::buffer<T,1> &result)
    }

```

Input Parameters

queue The queue where the routine should be executed.

n The number of elements in vectors **x** and **y**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx The stride of vector **x**.

y Buffer holding input vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details..

incy The stride of vector **y**.

Output Parameters

result The buffer where the result (a scalar) is stored.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

dotc (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void dotc(sycl::queue &queue,
              std::int64_t n,
              const T *x,

dotu

Computes the dot product of two complex vectors.

Description

The dotu routines perform a dot product between two complex vectors:

$$result = \sum_{i=1}^n X_i Y_i$$

dotu supports the following precisions.

T
std::complex<float>
std::complex<double>

dotu (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void dotu(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &result)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void dotu(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &result)
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vectors **x** and **y**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Buffer holding input vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

Output Parameters

result Buffer where the result (a scalar) is stored.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Parent topic: *BLAS Level 1 Routines*

nrm2

Computes the Euclidean norm of a vector.

Description

The `nrm2` routines computes Euclidean norm of a vector

$$result = \|x\|$$

where:

`x` is a vector of `n` elements.

`nrm2` supports the following precisions.

T	Tres
half	half
bfloat16	bfloat16
float	float
double	double
std::complex<float>	float
std::complex<double>	double

nrm2 (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void nrm2(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<Tres,1> &result)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void nrm2(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<Tres,1> &result)
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

Output Parameters

result Buffer where the Euclidean norm of the vector **x** will be stored.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

nrm2 (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event nrm2(sycl::queue &queue,
                   std::int64_t n,
                   const T *x,
                   std::int64_t incx,
                   Tres *result,
                   const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {

Parent topic: *BLAS Level 1 Routines*

rot

Performs rotation of points in the plane.

Description

Given two vectors **x** and **y** of **n** elements, the **rot** routines compute four scalar-vector products and update the input vectors with the sum of two of these scalar-vector products as follows:

$$\begin{bmatrix} x \\ y \end{bmatrix} \leftarrow \begin{bmatrix} c * x + s * y \\ -s * x + c * y \end{bmatrix}$$

If **s** is a complex type, the operation is defined as:

$$\begin{bmatrix} x \\ y \end{bmatrix} \leftarrow \begin{bmatrix} c * x + s * y \\ -\text{conj}(s) * x + c * y \end{bmatrix}$$

rot supports the following precisions.

T	Tc	Ts
sycl::half	sycl::half	sycl::half
oneapi::mkl::bfloat16	oneapi::mkl::bfloat16	oneapi::mkl::bfloat16
float	float	float
double	double	double
std::complex<float>	float	std::complex<float>
std::complex<double>	double	std::complex<double>
std::complex<float>	float	float
std::complex<double>	double	double

rot (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void rot(sycl::queue &queue,
            std::int64_t n,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &y,
            std::int64_t incy,
            Tc c,
            Ts s)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void rot(sycl::queue &queue,
            std::int64_t n,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &y,
            std::int64_t incy,
            Tc c,
            Ts s)
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Buffer holding input vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

c Scaling factor.

s Scaling factor.

Output Parameters

x Buffer holding updated buffer x.

y Buffer holding updated buffer y.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

rot (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event rot(sycl::queue &queue,
                  std::int64_t n,
                  T *x,
                  std::int64_t incx,
                  T *y,
                  std::int64_t incy,
                  Tc c,
                  Ts s,
                  const std::vector<sycl::event> &dependencies = {})
}

```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event rot(sycl::queue &queue,
                   std::int64_t n,
                   T *x,
                   std::int64_t incx,
                   T *y,
                   std::int64_t incy,
                   Tc c,
                   Ts s,
                   const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Pointer to input vector **x**. The array holding input vector **x** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Pointer to input vector **y**. The array holding input vector **y** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

c Scaling factor.

s Scaling factor.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

x Pointer to the updated matrix **x**.

y Pointer to the updated matrix **y**.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

rotg

Computes the parameters for a Givens rotation.

Description

Given the Cartesian coordinates (a, b) of a point, the `rotg` routines return the parameters c, s, r, and z associated with the Givens rotation. The parameters c and s define a unitary matrix such that:

$$\begin{bmatrix} c & s \\ -s & c \end{bmatrix} \cdot \begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

The parameter z is defined such that if $|a| > |b|$, z is s; otherwise if c is not 0 z is 1/c; otherwise z is 1.

`rotg` supports the following precisions.

T	Tc
float	float
double	double
std::complex<float>	float
std::complex<double>	double

rotg (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void rotg(sycl::queue &queue,
              sycl::buffer<T,1> &a,
              sycl::buffer<T,1> &b,
              sycl::buffer<Tc,1> &c,
              sycl::buffer<T,1> &s)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void rotg(sycl::queue &queue,
              sycl::buffer<T,1> &a,
              sycl::buffer<T,1> &b,
              sycl::buffer<Tc,1> &c,
              sycl::buffer<T,1> &s)
}
```

Input Parameters

queue The queue where the routine should be executed

- a** Buffer holding the x-coordinate of the point.
- b** Buffer holding the y-coordinate of the point.

Output Parameters

- a** Buffer holding the parameter *r* associated with the Givens rotation.
- b** Buffer holding the parameter *z* associated with the Givens rotation.
- c** Buffer holding the parameter *c* associated with the Givens rotation.
- s** Buffer holding the parameter *s* associated with the Givens rotation.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

rotg (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event rotg(sycl::queue &queue,
                    T *a,
                    T *b,
                    Tc *c,
                    T *s,
                    const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event rotg(sycl::queue &queue,
                    T *a,
                    T *b,
                    Tc *c,
                    T *s,
                    const std::vector<sycl::event> &dependencies = {})
}
```

Input Parameters

queue The queue where the routine should be executed

a Pointer to the x-coordinate of the point.

b Pointer to the y-coordinate of the point.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

a Pointer to the parameter *r* associated with the Givens rotation.

b Pointer to the parameter *z* associated with the Givens rotation.

c Pointer to the parameter *c* associated with the Givens rotation.

s Pointer to the parameter *s* associated with the Givens rotation.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

rotm

Performs modified Givens rotation of points in the plane.

Description

Given two vectors *x* and *y*, each vector element of these vectors is replaced as follows:

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} = H \begin{bmatrix} x_i \\ y_i \end{bmatrix}$$

for *i* from 1 to *n*, where *H* is a modified Givens transformation matrix.

rotm supports the following precisions.

T
float
double

rotm (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void rotm(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &param)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void rotm(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &param)
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector *x*.

x Buffer holding input vector *x*. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector *x*.

y Buffer holding input vector *x*. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector *y*.

param Buffer holding an array of size 5.

The elements of the **param** array are:

param[0] contains a switch, **flag**. The other array elements **param**[1-4] contain the components of the modified Givens transformation matrix *H*: h_{11} , h_{21} , h_{12} , and h_{22} , respectively.

Depending on the values of **flag**, the components of *H* are set as follows:

flag = -1.0:

$$H = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix}$$

flag = 0.0:

$$H = \begin{bmatrix} 1.0 & h_{12} \\ h_{21} & 1.0 \end{bmatrix}$$

flag = 1.0:

$$H = \begin{bmatrix} h_{11} & 1.0 \\ -1.0 & h_{22} \end{bmatrix}$$

flag = -2.0:

$$H = \begin{bmatrix} 1.0 & 0.0 \\ 0.0 & 1.0 \end{bmatrix}$$

In the last three cases, the matrix entries of 1.0, -1.0, and 0.0 are assumed based on the value of `flag` and are not required to be set in the `param` vector.

Output Parameters

- x** Buffer holding updated buffer x.
- y** Buffer holding updated buffer y.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

rotm (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event rotm(sycl::queue &queue,
                   std::int64_t n,
                   T *x,
                   std::int64_t incx,
                   T *y,

                   const T *param,
```

(continues on next page)

(continued from previous page)

```

    }
    const std::vector<sycl::event> &dependencies = {}
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event rotm(sycl::queue &queue,
        std::int64_t n,
        T *x,
        std::int64_t incx,
        T *y,
        std::int64_t incy,
        const T *param,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector *x*.

x Pointer to the input vector *x*. The array holding the vector *x* must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See [Matrix Storage](#) for more details.

incx Stride of vector *x*.

yparam Pointer to the input vector *y*. The array holding the vector *y* must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See [Matrix Storage](#) for more details.

incy Stride of vector *y*.

param Buffer holding an array of size 5.

The elements of the *param* array are:

param[0] contains a switch, *flag*. The other array elements *param*[1-4] contain the components of the modified Givens transformation matrix *H*: *h*₁₁, *h*₂₁, *h*₁₂, and *h*₂₂, respectively.

Depending on the values of *flag*, the components of *H* are set as follows:

flag = -1.0:

$$H = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix}$$

flag = 0.0:

$$H = \begin{bmatrix} 1.0 & h_{12} \\ h_{21} & 1.0 \end{bmatrix}$$

flag = 1.0:

$$H = \begin{bmatrix} h_{11} & 1.0 \\ -1.0 & h_{22} \end{bmatrix}$$

flag = -2.0:

$$H = \begin{bmatrix} 1.0 & 0.0 \\ 0.0 & 1.0 \end{bmatrix}$$

In the last three cases, the matrix entries of 1.0, -1.0, and 0.0 are assumed based on the value of `flag` and are not required to be set in the `param` vector.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

x Pointer to the updated array `x`.

y Pointer to the updated array `y`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

rotmg

Computes the parameters for a modified Givens rotation.

Description

Given Cartesian coordinates (`x1`, `y1`) of an input vector, the `rotmg` routines compute the components of a modified Givens transformation matrix `H` that zeros the `y`-component of the resulting vector:

$$\begin{bmatrix} x1 \\ 0 \end{bmatrix} = H \begin{bmatrix} x1\sqrt{d1} \\ y1\sqrt{d2} \end{bmatrix}$$

`rotmg` supports the following precisions.

T
float
double

rotmg (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void rotmg(sycl::queue &queue,
               sycl::buffer<T,1> &d1,
               sycl::buffer<T,1> &d2,
               sycl::buffer<T,1> &x1,
               sycl::buffer<T,1> y1,
               sycl::buffer<T,1> &param)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void rotmg(sycl::queue &queue,
               sycl::buffer<T,1> &d1,
               sycl::buffer<T,1> &d2,
               sycl::buffer<T,1> &x1,
               sycl::buffer<T,1> y1,
               sycl::buffer<T,1> &param)
}
```

Input Parameters

- queue** The queue where the routine should be executed.
- d1** Buffer holding the scaling factor for the x-coordinate of the input vector.
- d2** Buffer holding the scaling factor for the y-coordinate of the input vector.
- x1** Buffer holding the x-coordinate of the input vector.
- y1** Scalar specifying the y-coordinate of the input vector.

Output Parameters

- d1** Buffer holding the first diagonal element of the updated matrix.
- d2** Buffer holding the second diagonal element of the updated matrix.
- x1** Buffer holding the x-coordinate of the rotated vector before scaling
- param** Buffer holding an array of size 5.

The elements of the **param** array are:

param[0] contains a switch, **flag**. The other array elements **param**[1-4] contain the components of the modified Givens transformation matrix **H**: h_{11} , h_{21} , h_{12} , and h_{22} , respectively.

Depending on the values of **flag**, the components of **H** are set as follows:

flag = -1.0:

$$H = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix}$$

flag = 0.0:

$$H = \begin{bmatrix} 1.0 & h_{12} \\ h_{21} & 1.0 \end{bmatrix}$$

flag = 1.0:

$$H = \begin{bmatrix} h_{11} & 1.0 \\ -1.0 & h_{22} \end{bmatrix}$$

flag = -2.0:

$$H = \begin{bmatrix} 1.0 & 0.0 \\ 0.0 & 1.0 \end{bmatrix}$$

In the last three cases, the matrix entries of 1.0, -1.0, and 0.0 are assumed based on the value of `flag` and are not required to be set in the `param` vector.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

rotmg (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event rotmg(sycl::queue &queue,
                    T *d1,
                    T *d2,
                    T *x1,
                    T y1,
                    T *param,
                    const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event rotmg(sycl::queue &queue,
                    T *d1,
                    T *d2,
```

(continues on next page)

(continued from previous page)

```

    T *x1,
    T  y1,
    T *param,
    const std::vector<ycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

d1 Pointer to the scaling factor for the x-coordinate of the input vector.

d2 Pointer to the scaling factor for the y-coordinate of the input vector.

x1 Pointer to the x-coordinate of the input vector.

y1 Scalar specifying the y-coordinate of the input vector.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

d1 Pointer to the first diagonal element of the updated matrix.

d2 Pointer to the second diagonal element of the updated matrix.

x1 Pointer to the x-coordinate of the rotated vector before scaling

param Buffer holding an array of size 5.

The elements of the **param** array are:

param[0] contains a switch, **flag**. The other array elements **param[1-4]** contain the components of the modified Givens transformation matrix **H**: h_{11} , h_{21} , h_{12} , and h_{22} , respectively.

Depending on the values of **flag**, the components of **H** are set as follows:

flag = -1.0:

$$H = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix}$$

flag = 0.0:

$$H = \begin{bmatrix} 1.0 & h_{12} \\ h_{21} & 1.0 \end{bmatrix}$$

flag = 1.0:

$$H = \begin{bmatrix} h_{11} & 1.0 \\ -1.0 & h_{22} \end{bmatrix}$$

flag = -2.0:

$$H = \begin{bmatrix} 1.0 & 0.0 \\ 0.0 & 1.0 \end{bmatrix}$$

In the last three cases, the matrix entries of 1.0, -1.0, and 0.0 are assumed based on the value of `flag` and are not required to be set in the `param` vector.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

scal

Computes the product of a vector by a scalar.

Description

The `scal` routines computes a scalar-vector product:

$$x \leftarrow \alpha * x$$

where:

`x` is a vector of `n` elements,

`alpha` is a scalar.

`scal` supports the following precisions.

T	Ts
half	half
bfloat16	bfloat16
float	float
double	double
std::complex<float>	std::complex<float>
std::complex<double>	std::complex<double>
std::complex<float>	float
std::complex<double>	double

scal (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void scal(sycl::queue &queue,
              std::int64_t n,
              Ts alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void scal(sycl::queue &queue,
              std::int64_t n,
              Ts alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

alpha Specifies the scalar **alpha**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

Output Parameters

x Buffer holding updated buffer **x**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

scal (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event scal(sycl::queue &queue,
                    std::int64_t n,
                    Ts alpha,
                    T *x,
                    std::int64_t incx,
                    const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event scal(sycl::queue &queue,
                    std::int64_t n,
                    Ts alpha,
                    T *x,
                    std::int64_t incx,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

alpha Specifies the scalar **alpha**.

x Pointer to the input vector **x**. The array must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

Output Parameters

x Pointer to the updated array **x**.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

swap

Swaps a vector with another vector.

Description

Given two vectors of n elements, x and y , the `swap` routines return vectors y and x swapped, each replacing the other.

$$\begin{bmatrix} y \\ x \end{bmatrix} \leftarrow \begin{bmatrix} x \\ y \end{bmatrix}$$

`swap` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

swap (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void swap(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void swap(sycl::queue &queue,
              std::int64_t n,
              sycl::buffer<T,1> &x,
```

(continues on next page)

(continued from previous page)

```

        std::int64_t incx,
        sycl::buffer<T,1> &y,
        std::int64_t incy)
    }

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Buffer holding input vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

Output Parameters

x Buffer holding updated buffer **x**, that is, the input vector **y**.

y Buffer holding updated buffer **y**, that is, the input vector **x**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

swap (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event swap(sycl::queue &queue,
        std::int64_t n,
        T *x,
        std::int64_t incx,
        T *y,
        std::int64_t incy,

```

(continues on next page)

(continued from previous page)

```

    const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event swap(sycl::queue &queue,
        std::int64_t n,
        T *x,
        std::int64_t incx,
        T *y,
        std::int64_t incy,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector *x*.

x Pointer to the input vector *x*. The array must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector *x*.

y Pointer to the input vector *y*. The array must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector *y*.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

x Pointer to the updated array *x*, that is, the input vector *y*.

y Pointer to the updated array *y*, that is, the input vector *x*.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

iamax

Finds the index of the element with the largest absolute value in a vector.

Description

The `iamax` routines return an index `i` such that `x[i]` has the maximum absolute value of all elements in vector `x` (real variants), or such that $(|\operatorname{Re}(x[i])| + |\operatorname{Im}(x[i])|)$ is maximal (complex variants).

If either `n` or `incx` are not positive, the routine returns `0`.

If more than one vector element is found with the same largest absolute value, the index of the first one encountered is returned.

If the vector contains NaN values, then the routine returns the index of the first NaN.

`iamax` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Note

The index is zero-based.

iamax (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void iamax(sycl::queue &queue,
               std::int64_t n,
               sycl::buffer<T,1> &x,
               std::int64_t incx,
               sycl::buffer<std::int64_t,1> &result)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void iamax(sycl::queue &queue,
               std::int64_t n,
               sycl::buffer<T,1> &x,
               std::int64_t incx,
               sycl::buffer<std::int64_t,1> &result)
}
```

Input Parameters

queue The queue where the routine should be executed.

n The number of elements in vector **x**.

x The buffer that holds the input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx The stride of vector **x**.

Output Parameters

result The buffer where the zero-based index **i** of the maximal element is stored.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 1 Routines*

iamin

Finds the index of the element with the smallest absolute value.

Description

The `iamin` routines return an index **i** such that $x[i]$ has the minimum absolute value of all elements in vector **x** (real variants), or such that $(|\text{Re}(x[i])| + |\text{Im}(x[i])|)$ is minimal (complex variants).

If either **n** or **incx** are not positive, the routine returns 0.

If more than one vector element is found with the same smallest absolute value, the index of the first one encountered is returned.

If the vector contains NaN values, then the routine returns the index of the first NaN.

`iamin` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Note

The index is zero-based.

iamin (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void iamin(sycl::queue &queue,
               std::int64_t n,
               sycl::buffer<T,1> &x,
               std::int64_t incx,
               sycl::buffer<std::int64_t,1> &result)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void iamin(sycl::queue &queue,
               std::int64_t n,
               sycl::buffer<T,1> &x,
               std::int64_t incx,
               sycl::buffer<std::int64_t,1> &result)
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

Output Parameters

result Buffer where the zero-based index *i* of the minimum element will be stored.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

iamin (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event iamin(sycl::queue &queue,
                    std::int64_t n,
                    const T *x,
                    std::int64_t incx,
                    std::int64_t *result,

BLAS Level 2 Routines

BLAS Level 2 includes routines which perform matrix-vector operations as described in the following table.

Routines	Description
<i>gbmv</i>	Matrix-vector product using a general band matrix
<i>gemv</i>	Matrix-vector product using a general matrix
<i>ger</i>	Rank-1 update of a general matrix
<i>gerc</i>	Rank-1 update of a conjugated general matrix
<i>geru</i>	Rank-1 update of a general matrix, unconjugated
<i>hbmV</i>	Matrix-vector product using a Hermitian band matrix
<i>hemv</i>	Matrix-vector product using a Hermitian matrix
<i>her</i>	Rank-1 update of a Hermitian matrix
<i>her2</i>	Rank-2 update of a Hermitian matrix
<i>hpmv</i>	Matrix-vector product using a Hermitian packed matrix
<i>hpr</i>	Rank-1 update of a Hermitian packed matrix
<i>hpr2</i>	Rank-2 update of a Hermitian packed matrix
<i>sbmv</i>	Matrix-vector product using symmetric band matrix
<i>spmv</i>	Matrix-vector product using a symmetric packed matrix
<i>spr</i>	Rank-1 update of a symmetric packed matrix
<i>spr2</i>	Rank-2 update of a symmetric packed matrix
<i>symv</i>	Matrix-vector product using a symmetric matrix
<i>syr</i>	Rank-1 update of a symmetric matrix
<i>syr2</i>	Rank-2 update of a symmetric matrix
<i>tbmV</i>	Matrix-vector product using a triangular band matrix
<i>tbsv</i>	Solution of a linear system of equations with a triangular band matrix
<i>tpmv</i>	Matrix-vector product using a triangular packed matrix
<i>tpsv</i>	Solution of a linear system of equations with a triangular packed matrix
<i>trmv</i>	Matrix-vector product using a triangular matrix
<i>trsv</i>	Solution of a linear system of equations with a triangular matrix

gbmv

Computes a matrix-vector product with a general band matrix.

Description

The *gbmv* routines compute a scalar-matrix-vector product and add the result to a scalar-vector product, with a general band matrix. The operation is defined as

$$y \leftarrow \alpha * op(A) * x + \beta * y$$

where:

$op(A)$ is one of $op(A) = A$, or $op(A) = A^T$, or $op(A) = A^H$,

α and β are scalars,

A is an m -by- n matrix with kl sub-diagonals and ku super-diagonals,

x and y are vectors.

gbmv supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

gbmv (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void gbmv(sycl::queue &queue,
              onemkl::transpose trans,
              std::int64_t m,
              std::int64_t n,
              std::int64_t kl,
              std::int64_t ku,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void gbmv(sycl::queue &queue,
              onemkl::transpose trans,
              std::int64_t m,
              std::int64_t n,
              std::int64_t kl,
              std::int64_t ku,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(A)$, the transposition operation applied to A . See *oneMKL defined datatypes* for more details.

m Number of rows of A . Must be at least zero.

n Number of columns of A . Must be at least zero.

kl Number of sub-diagonals of the matrix A . Must be at least zero.

ku Number of super-diagonals of the matrix A . Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Buffer holding input matrix A . Must have size at least $lda*n$ if column major layout is used or at least $lda*m$ if row major layout is used. See *Matrix Storage* for more details.

lda Leading dimension of matrix A . Must be at least $(kl + ku + 1)$, and positive.

x Buffer holding input vector x . The length len of vector x is n if A is not transposed, and m if A is transposed. The buffer must be of size at least $(1 + (len - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x .

beta Scaling factor for vector y .

y Buffer holding input/output vector y . The length len of vector y is m , if A is not transposed, and n if A is transposed. The buffer must be of size at least $(1 + (len - 1)*abs(incy))$ where len is this length. See *Matrix Storage* for more details.

incy Stride of vector y .

Output Parameters

y Buffer holding the updated vector y .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event gbmv(sycl::queue &queue,
                    onemkl::transpose trans,
                    std::int64_t m,
                    std::int64_t n,
                    std::int64_t kl,
                    std::int64_t ku,
                    T alpha,
                    const T *a,
                    std::int64_t lda,
                    const T *x,
                    std::int64_t incx,
                    T beta,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(A)$, the transposition operation applied to A . See *oneMKL defined datatypes* for more details.

m Number of rows of A . Must be at least zero.

n Number of columns of A . Must be at least zero.

kl Number of sub-diagonals of the matrix A . Must be at least zero.

ku Number of super-diagonals of the matrix A . Must be at least zero.

alpha Scaling factor for the matrix-vector product.

- a** Pointer to input matrix A. The array holding input matrix A must have size at least $\text{lda} * n$ if column major layout is used or at least $\text{lda} * m$ if row major layout is used. See *Matrix Storage* for more details.
- lda** Leading dimension of matrix A. Must be at least $(k_l + k_u + 1)$, and positive.
- x** Pointer to input vector x. The length `len` of vector x is `n` if A is not transposed, and `m` if A is transposed. The array holding input vector x must be of size at least $(1 + (\text{len} - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.
- incx** Stride of vector x.
- beta** Scaling factor for vector y.
- y** Pointer to input/output vector y. The length `len` of vector y is `m`, if A is not transposed, and `n` if A is transposed. The array holding input/output vector y must be of size at least $(1 + (\text{len} - 1) * \text{abs}(\text{incy}))$ where `len` is this length. See *Matrix Storage* for more details.
- incy** Stride of vector y.
- dependencies** List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

- y** Pointer to the updated vector y.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Parent topic: *BLAS Level 2 Routines*

gemv

Computes a matrix-vector product using a general matrix.

Description

The `gemv` routines compute a scalar-matrix-vector product and add the result to a scalar-vector product, with a general matrix. The operation is defined as:

$$y \leftarrow \alpha * op(A) * x + \beta * y$$

where:

`op(A)` is one of `op(A) = A`, or `op(A) = AT`, or `op(A) = AH`,

`alpha` and `beta` are scalars,

`A` is an `m`-by-`n` matrix, and `x`, `y` are vectors.

`gemv` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

gemv (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void gemv(sycl::queue &queue,
              onemkl::transpose trans,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void gemv(sycl::queue &queue,
              onemkl::transpose trans,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
```

(continues on next page)

(continued from previous page)

```

    sycl::buffer<T, 1> &y,
    std::int64_t incy)
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(A)$, the transposition operation applied to A .

m Specifies the number of rows of the matrix A . The value of m must be at least zero.

n Specifies the number of columns of the matrix A . The value of n must be at least zero.

alpha Scaling factor for the matrix-vector product.

a The buffer holding the input matrix A . Must have a size of at least $lda*n$ if column major layout is used or at least $lda*m$ if row major layout is used. See *Matrix Storage* for more details.

lda Leading dimension of matrix A . Must be positive and at least m if column major layout is used or at least n if row major layout is used.

x Buffer holding input vector x . The length len of vector x is n if A is not transposed, and m if A is transposed. The buffer must be of size at least $(1 + (len - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx The stride of vector x .

beta The scaling factor for vector y .

y Buffer holding input/output vector y . The length len of vector y is m , if A is not transposed, and n if A is transposed. The buffer must be of size at least $(1 + (len - 1)*abs(incy))$ where len is this length. See *Matrix Storage* for more details.

incy The stride of vector y .

Output Parameters

y The buffer holding updated vector y .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

gemv (USM Version)

Syntax

```

                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(A)$, the transposition operation applied to **A**. See *oneMKL defined datatypes* for more details.

m Specifies the number of rows of the matrix **A**. The value of **m** must be at least zero.

n Specifies the number of columns of the matrix **A**. The value of **n** must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Pointer to the input matrix **A**. Must have a size of at least $lda*n$ if column major layout is used or at least $lda*m$ if row major layout is used. See *Matrix Storage* for more details.

lda Leading dimension of matrix **A**. Must be positive and at least **m** if column major layout is used or at least **n** if row major layout is used.

x Pointer to the input vector **x**. The length **len** of vector **x** is **n** if **A** is not transposed, and **m** if **A** is transposed. The array holding vector **x** must be of size at least $(1 + (\text{len} - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx The stride of vector **x**.

beta The scaling factor for vector **y**.

y Pointer to input/output vector **y**. The length **len** of vector **y** is **m**, if **A** is not transposed, and **n** if **A** is transposed. The array holding input/output vector **y** must be of size at least $(1 + (\text{len} - 1) * \text{abs}(\text{incy}))$ where **len** is this length. See *Matrix Storage* for more details.

incy The stride of vector **y**.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y The pointer to updated vector **y**.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

ger

Computes a rank-1 update of a general matrix.

Description

The **ger** routines compute a scalar-vector-vector product and add the result to a general matrix. The operation is defined as:

$$A \leftarrow \text{alpha} * x * y^T + A$$

where:

alpha is scalar,

A is an **m**-by-**n** matrix,

x is a vector of length **m**,

y is a vector of length **n**.

ger supports the following precisions.

T
float
double

ger (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void ger(sycl::queue &queue,
            std::int64_t m,
            std::int64_t n,
            T alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &y,
            std::int64_t incy,
            sycl::buffer<T,1> &a,
            std::int64_t lda)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void ger(sycl::queue &queue,
            std::int64_t m,
            std::int64_t n,
            T alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &y,
            std::int64_t incy,
            sycl::buffer<T,1> &a,
            std::int64_t lda)
}
```

Input Parameters

queue The queue where the routine should be executed.

m Number of rows of **A**. Must be at least zero.

n Number of columns of **A**. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (m - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Buffer holding input/output vector *y*. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector *y*.

a Buffer holding input matrix *A*. Must have size at least $\text{lda} * n$ if column major layout is used or at least $\text{lda} * m$ if row major layout is used. See *Matrix Storage* for more details.

lda Leading dimension of matrix *A*. Must be positive and at least *m* if column major layout is used or at least *n* if row major layout is used.

Output Parameters

a Buffer holding the updated matrix *A*.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

gerc

Computes a rank-1 update (conjugated) of a general complex matrix.

Description

The gerc routines compute a scalar-vector-vector product and add the result to a general matrix. The operation is defined as:

$$A \leftarrow \alpha * x * y^H + A$$

where:

alpha is a scalar,

A is an m-by-n matrix,

x is a vector of length m,

y is vector of length n.

gerc supports the following precisions.

T
std::complex<float>
std::complex<double>

gerc (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void gerc(sycl::queue &queue,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &a,
              std::int64_t lda)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void gerc(sycl::queue &queue,
              std::int64_t m,
              std::int64_t n,
```

(continues on next page)

(continued from previous page)

```

    T alpha,
    sycl::buffer<T,1> &x,
    std::int64_t incx,
    sycl::buffer<T,1> &y,
    std::int64_t incy,
    sycl::buffer<T,1> &a,
    std::int64_t lda)
}

```

Input Parameters

queue The queue where the routine should be executed.

m Number of rows of A. Must be at least zero.

n Number of columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (m - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

y Buffer holding input/output vector y. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector y.

a Buffer holding input matrix A. Must have size at least $\text{lda} * n$ if column major layout is used or at least $\text{lda} * m$ if row major layout is used. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be positive and at least m if column major layout is used or at least n if row major layout is used.

Output Parameters

a Buffer holding the updated matrix A.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

geru

Computes a rank-1 update (unconjugated) of a general complex matrix.

Description

The geru routines compute a scalar-vector-vector product and add the result to a general matrix. The operation is defined as

$$A \leftarrow \alpha * x * y^T + A$$

where:

α is a scalar,

A is an m -by- n matrix,

x is a vector of length m ,

y is a vector of length n .

geru supports the following precisions.

T
std::complex<float>
std::complex<double>

geru (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void geru(sycl::queue &queue,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &a,
              std::int64_t lda)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void geru(sycl::queue &queue,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &a,
              std::int64_t lda)
}

```

Input Parameters

queue The queue where the routine should be executed.

m Number of rows of A. Must be at least zero.

n Number of columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (m - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

y Buffer holding input/output vector y. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector y.

a Buffer holding input matrix A. Must have size at least $\text{lda} * n$ if column major layout is used or at least $\text{lda} * m$ if row major layout is used. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be positive and at least m if column major layout is used or at least n if row major layout is used.

Output Parameters

- a Buffer holding the updated matrix A.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

}

```

Input Parameters

queue The queue where the routine should be executed.

m Number of rows of A. Must be at least zero.

n Number of columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Pointer to the input vector **x**. The array holding input vector **x** must be of size at least $(1 + (m - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Pointer to input/output vector **y**. The array holding input/output vector **y** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

a Pointer to input matrix A. The array holding input matrix A must have size at least $\text{lda} * n$ if column major layout is used or at least $\text{lda} * m$ if row major layout is used. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be positive and at least **m** if column major layout is used or at least **n** if row major layout is used.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

a Pointer to the updated matrix A.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

hbmv

Computes a matrix-vector product using a Hermitian band matrix.

Description

The `hbmv` routines compute a scalar-matrix-vector product and add the result to a scalar-vector product, with a Hermitian band matrix. The operation is defined as

$$y \leftarrow \alpha * A * x + \beta * y$$

where:

`alpha` and `beta` are scalars,

`A` is an `n`-by-`n` Hermitian band matrix, with `k` super-diagonals,

`x` and `y` are vectors of length `n`.

`hbmv` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

hbmv (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void hbmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void hbmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
```

(continues on next page)

(continued from previous page)

```

    sycl::buffer<T,1> &x,
    std::int64_t incx,
    T beta,
    sycl::buffer<T,1> &y,
    std::int64_t incy)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

k Number of super-diagonals of the matrix A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Buffer holding input matrix A. Must have size at least $lda * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least $(k + 1)$, and positive.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) * abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

beta Scaling factor for vector y.

y Buffer holding input/output vector y. The buffer must be of size at least $(1 + (n - 1) * abs(incy))$. See *Matrix Storage* for more details.

incy Stride of vector y.

Output Parameters

y Buffer holding the updated vector y.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

hemv

Computes a matrix-vector product using a Hermitian matrix.

Description

The **hemv** routines compute a scalar-matrix-vector product and add the result to a scalar-vector product, with a Hermitian matrix. The operation is defined as

$$y \leftarrow \alpha * A * x + \beta * y$$

where:

alpha and **beta** are scalars,

A is an **n**-by-**n** Hermitian matrix,

x and **y** are vectors of length **n**.

hemv supports the following precisions.

T
std::complex<float>
std::complex<double>

hemv (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void hemv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void hemv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether *A* is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of *A*. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Buffer holding input matrix *A*. Must have size at least *lda***n*. See *Matrix Storage* for more details.

lda Leading dimension of matrix *A*. Must be at least *m*, and positive.

x Buffer holding input vector *x*. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector *x*.

beta Scaling factor for vector *y*.

y Buffer holding input/output vector *y*. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector *y*.

Output Parameters

y Buffer holding the updated vector *y*.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

her

Computes a rank-1 update of a Hermitian matrix.

Description

The her routines compute a scalar-vector-vector product and add the result to a Hermitian matrix. The operation is defined as:

$$A \leftarrow \alpha * x * x^H + A$$

where:

alpha is scalar,

A is an n-by-n Hermitian matrix,

x is a vector of length n.

her supports the following precisions.

T	Treal
std::complex<float>	float
std::complex<double>	double

her (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void her(sycl::queue &queue,
            onemkl::uplo upper_lower,
            std::int64_t n,
            Treal alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &a,
            std::int64_t lda)
}

```

```
namespace oneapi::mkl::blas::row_major {
    void her(sycl::queue &queue,
            onemkl::uplo upper_lower,
            std::int64_t n,
            Treal alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &a,
            std::int64_t lda)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

a Buffer holding input matrix A. Must have size at least $\text{lda} * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least **n**, and positive.

Output Parameters

a Buffer holding the updated upper triangular part of the Hermitian matrix A if **upper_lower** = upper or the updated lower triangular part of the Hermitian matrix A if **upper_lower**=lower.

The imaginary parts of the diagonal elements are set to zero.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

her2

Computes a rank-2 update of a Hermitian matrix.

Description

The `her2` routines compute two scalar-vector-vector products and add them to a Hermitian matrix. The operation is defined as:

$$A \leftarrow \alpha * x * y^H + \text{conjg}(\alpha) * y * x^H + A$$

where:

`alpha` is a scalar,

`A` is an `n`-by-`n` Hermitian matrix,

`x` and `y` are vectors of length `n`.

`her2` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

her2 (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void her2(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,

                   std::int64_t incx,
                   const T *y,
                   std::int64_t incy,
                   T *a,
                   std::int64_t lda,
                   const std::vector<sycl::event> &dependencies = {})
}

```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event her2(sycl::queue &queue,
                   onemkl::uplo upper_lower,
                   std::int64_t n,
                   T alpha,
                   const T *x,
                   std::int64_t incx,
                   const T *y,
                   std::int64_t incy,
                   T *a,
                   std::int64_t lda,
                   const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

y Pointer to input/output vector y. The array holding input/output vector y must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector y.

a Pointer to input matrix A. The array holding input matrix A must have size at least $\text{lda} * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least n, and positive.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

a Pointer to the updated upper triangular part of the Hermitian matrix A if `upper_lower=upper`, or the updated lower triangular part of the Hermitian matrix A if `upper_lower=lower`.

The imaginary parts of the diagonal elements are set to zero.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

hpmv

Computes a matrix-vector product using a Hermitian packed matrix.

Description

The `hpmv` routines compute a scalar-matrix-vector product and add the result to a scalar-vector product, with a Hermitian packed matrix. The operation is defined as

$$y \leftarrow \alpha * A * x + \beta * y$$

where:

`alpha` and `beta` are scalars,

`A` is an `n`-by-`n` Hermitian matrix supplied in packed form,

`x` and `y` are vectors of length `n`.

`hpmv` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

hpmv (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void hpmv(sycl::queue &queue,
             onemkl::uplo upper_lower,
             std::int64_t n,
             T alpha,
             sycl::buffer<T,1> &a,
             sycl::buffer<T,1> &x,
             std::int64_t incx,
             T beta,
             sycl::buffer<T,1> &y,
             std::int64_t incy)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void hpmv(sycl::queue &queue,
             onemkl::uplo upper_lower,
             std::int64_t n,
             T alpha,
             sycl::buffer<T,1> &a,
             sycl::buffer<T,1> &x,
             std::int64_t incx,
             T beta,
             sycl::buffer<T,1> &y,
```

(continues on next page)

(continued from previous page)

```

        std::int64_t incy)
    }

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Buffer holding input matrix A. Must have size at least $(n*(n+1))/2$. See *Matrix Storage* for more details.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

beta Scaling factor for vector y.

y Buffer holding input/output vector y. The buffer must be of size at least $(1 + (n - 1)*abs(incy))$. See *Matrix Storage* for more details.

incy Stride of vector y.

Output Parameters

y Buffer holding the updated vector y.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

hpmv (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event hpmv(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    std::int64_t n,
                    T alpha,
                    const T *a,
                    const T *x,
                    std::int64_t incx,

                    T alpha,
                    const T *a,
                    const T *x,
                    std::int64_t incx,
                    T beta,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Pointer to input matrix A. The array holding input matrix A must have size at least $(n*(n+1))/2$. See *Matrix Storage* for more details.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

beta Scaling factor for vector y.

y Pointer to input/output vector y. The array holding input/output vector y must be of size at least $(1 + (n - 1)*abs(incy))$. See *Matrix Storage* for more details.

incy Stride of vector *y*.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Pointer to the updated vector *y*.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

hpr

Computes a rank-1 update of a Hermitian packed matrix.

Description

The *hpr* routines compute a scalar-vector-vector product and add the result to a Hermitian packed matrix. The operation is defined as

$$A \leftarrow \alpha * x * x^H + A$$

where:

alpha is scalar,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form,

x is a vector of length *n*.

hpr supports the following precisions.

T	Treal
std::complex<float>	float
std::complex<double>	double

hpr (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void hpr(sycl::queue &queue,
            onemkl::uplo upper_lower,
            std::int64_t n,
            Treal alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &a)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void hpr(sycl::queue &queue,
            onemkl::uplo upper_lower,
            std::int64_t n,
            Treal alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &a)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

a Buffer holding input matrix A. Must have size at least $(n * (n - 1)) / 2$. See *Matrix Storage* for more details.

The imaginary part of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

a Buffer holding the updated upper triangular part of the Hermitian matrix A if `upper_lower=upper`, or the updated lower triangular part of the Hermitian matrix A if `upper_lower=lower`.

The imaginary parts of the diagonal elements are set to zero.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

hpr2

Performs a rank-2 update of a Hermitian packed matrix.

Description

The `hpr2` routines compute two scalar-vector-vector products and add them to a Hermitian packed matrix. The operation is defined as

$$A \leftarrow \alpha * x * y^H + \text{conjg}(\alpha) * y * x^H + A$$

where:

`alpha` is a scalar,

`A` is an `n`-by-`n` Hermitian matrix, supplied in packed form,

`x` and `y` are vectors of length `n`.

`hpr2` supports the following precisions.

T
std::complex<float>
std::complex<double>

hpr2 (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void hpr2(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &a)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void hpr2(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &a)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

y Buffer holding input/output vector y. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector y.

a Buffer holding input matrix A. Must have size at least $(n * (n - 1)) / 2$. See *Matrix Storage* for more details.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

- a Buffer holding the updated upper triangular part of the Hermitian matrix A if `upper_lower=upper`, or the updated lower triangular part of the Hermitian matrix A if `upper_lower=lower`.

The imaginary parts of the diagonal elements are set to zero.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

sbmv

Computes a matrix-vector product with a symmetric band matrix.

Description

The `sbmv` routines compute a scalar-matrix-vector product and add the result to a scalar-vector product, with a symmetric band matrix. The operation is defined as:

$$y \leftarrow \alpha * A * x + \beta * y$$

where:

`alpha` and `beta` are scalars,

`A` is an `n`-by-`n` symmetric matrix with `k` super-diagonals,

`x` and `y` are vectors of length `n`.

`sbmv` supports the following precisions.

T
float
double

sbmv (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void sbmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void sbmv(sycl::queue &queue,
              onemkl::uplo upper_lower,

              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,

```

(continues on next page)

(continued from previous page)

```

    sycl::buffer<T,1> &x,
    std::int64_t incx,
    T beta,
    sycl::buffer<T,1> &y,
    std::int64_t incy)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

k Number of super-diagonals of the matrix A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Buffer holding input matrix A. Must have size at least $lda * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least $(k + 1)$, and positive.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) * abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

beta Scaling factor for vector y.

y Buffer holding input/output vector y. The buffer must be of size at least $(1 + (n - 1) * abs(incy))$. See *Matrix Storage* for more details.

incy Stride of vector y.

Output Parameters

y Buffer holding the updated vector y.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

                    onemkl::uplo upper_lower,
                    std::int64_t n,
                    std::int64_t k,
                    T alpha,
                    const T *a,
                    std::int64_t lda,
                    const T *x,
                    std::int64_t incx,
                    T beta,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

k Number of super-diagonals of the matrix A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Pointer to input matrix A. The array holding input matrix A must have size at least $lda \cdot n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least $(k + 1)$, and positive.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1) \cdot \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

beta Scaling factor for vector **y**.

y Pointer to input/output vector **y**. The array holding input/output vector **y** must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Pointer to the updated vector **y**.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

spmv

Computes a matrix-vector product with a symmetric packed matrix.

Description

The `spmv` routines compute a scalar-matrix-vector product and add the result to a scalar-vector product, with a symmetric packed matrix. The operation is defined as:

$$y \leftarrow \alpha * A * x + \beta * y$$

where:

alpha and **beta** are scalars,

A is an **n**-by-**n** symmetric matrix, supplied in packed form,

x and **y** are vectors of length **n**.

`spmv` supports the following precisions.

T
float
double

spmv (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void spmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void spmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Buffer holding input matrix A. Must have size at least $(n*(n+1))/2$. See *Matrix Storage* for more details.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

beta Scaling factor for vector y.

y Buffer holding input/output vector *y*. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector *y*.

Output Parameters

y Buffer holding the updated vector *y*.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

spmv (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event spmv(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    std::int64_t n,
                    T alpha,
                    const T *a,
                    const T *x,
                    std::int64_t incx,
                    T beta,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}
```

```

    sycl::event spmv(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    std::int64_t n,
                    T alpha,
                    const T *a,
                    const T *x,
                    std::int64_t incx,
                    T beta,
                    T *y,
                    std::int64_t incy,
```

(continues on next page)

(continued from previous page)

```

}
    const std::vector<sycl::event> &dependencies = {})

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Pointer to input matrix A. The array holding input matrix A must have size at least $(n*(n+1))/2$. See *Matrix Storage* for more details.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

beta Scaling factor for vector y.

y Pointer to input/output vector y. The array holding input/output vector y must be of size at least $(1 + (n - 1)*abs(incy))$. See *Matrix Storage* for more details.

incy Stride of vector y.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Pointer to the updated vector y.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

spr

Performs a rank-1 update of a symmetric packed matrix.

Description

The `spr` routines compute a scalar-vector-vector product and add the result to a symmetric packed matrix. The operation is defined as:

$$A \leftarrow \alpha * x * x^T + A$$

where:

`alpha` is scalar,

`A` is an `n`-by-`n` symmetric matrix, supplied in packed form,

`x` is a vector of length `n`.

`spr` supports the following precisions.

T
float
double

spr (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void spr(sycl::queue &queue,
            onemkl::uplo upper_lower,
            std::int64_t n,
            T alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &a)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void spr(sycl::queue &queue,
            onemkl::uplo upper_lower,
            std::int64_t n,
            T alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &a)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

a Buffer holding input matrix A. Must have size at least $(n * (n + 1)) / 2$. See *Matrix Storage* for more details.

Output Parameters

a Buffer holding the updated upper triangular part of the symmetric matrix A if `upper_lower=upper`, or the updated lower triangular part of the symmetric matrix A if `upper_lower=lower`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

spr2

Computes a rank-2 update of a symmetric packed matrix.

Description

The `spr2` routines compute two scalar-vector-vector products and add them to a symmetric packed matrix. The operation is defined as:

$$A \leftarrow \alpha * x * y^T + \alpha * y * x^T + A$$

where:

`alpha` is scalar,

`A` is an `n`-by-`n` symmetric matrix, supplied in packed form,

`x` and `y` are vectors of length `n`.

`spr` supports the following precisions.

T
float
double

spr2 (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void spr2(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &a)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void spr2(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &a)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

y Buffer holding input/output vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector **y**.

a Buffer holding input matrix A. Must have size at least $(n * (n - 1)) / 2$. See *Matrix Storage* for more details.

Output Parameters

a Buffer holding the updated upper triangular part of the symmetric matrix A if `upper_lower=upper` or the updated lower triangular part of the symmetric matrix A if `upper_lower=lower`.

symv

Computes a matrix-vector product for a symmetric matrix.

Description

The `symv` routines compute a scalar-matrix-vector product and add the result to a scalar-vector product, with a symmetric matrix. The operation is defined as:

$$y \leftarrow \alpha * A * x + \beta * y$$

where:

`alpha` and `beta` are scalars,

`A` is an `n`-by-`n` symmetric matrix,

`x` and `y` are vectors of length `n`.

`symv` supports the following precisions.

T
float
double

symv (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void symv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
```

(continues on next page)

(continued from previous page)

```

    T alpha,
    sycl::buffer<T,1> &a,
    std::int64_t lda,
    sycl::buffer<T,1> &x,
    std::int64_t incx,
    T beta,
    sycl::buffer<T,1> &y,
    std::int64_t incy)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void symv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y,
              std::int64_t incy)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Buffer holding input matrix A. Must have size at least $lda * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least m , and positive.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

y Buffer holding input/output vector y. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector y.

Output Parameters

y Buffer holding the updated vector **y**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

                    T alpha,
                    const T *a,
                    std::int64_t lda,
                    const T *x,
                    std::int64_t incx,
                    T beta,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event symv(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    std::int64_t n,
                    T alpha,
                    const T *a,
                    std::int64_t lda,
                    const T *x,
                    std::int64_t incx,
                    T beta,
                    T *y,
                    std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

a Pointer to input matrix A. The array holding input matrix A must have size at least $lda * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least m, and positive.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

y Pointer to input/output vector y. The array holding input/output vector y must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector y.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Pointer to the updated vector y.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

syr

Computes a rank-1 update of a symmetric matrix.

Description

The `syr` routines compute a scalar-vector-vector product add them and add the result to a matrix, with a symmetric matrix. The operation is defined as:

$$A \leftarrow \alpha * x * x^T + A$$

where:

`alpha` is scalar,

`A` is an `n`-by-`n` symmetric matrix,

`x` is a vector of length `n`.

`syr` supports the following precisions.

T
float
double

syr (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void syr(sycl::queue &queue,
            onemkl::uplo upper_lower,
            std::int64_t n,
            T alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &a,
            std::int64_t lda)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void syr(sycl::queue &queue,
            onemkl::uplo upper_lower,
            std::int64_t n,
            T alpha,
            sycl::buffer<T,1> &x,
            std::int64_t incx,
            sycl::buffer<T,1> &a,
            std::int64_t lda)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector **x**.

a Buffer holding input matrix A. Must have size at least $\text{lda} * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least **n**, and positive.

Output Parameters

a Buffer holding the updated upper triangular part of the symmetric matrix A if **upper_lower=upper** or the updated lower triangular part of the symmetric matrix A if **upper_lower=lower**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

syr (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event syr(sycl::queue &queue,
                  onemkl::uplo upper_lower,
                  std::int64_t n,
                  T alpha,
                  const T *x,
                  std::int64_t incx,
                  T *a,
                  std::int64_t lda,
                  const std::vector<sycl::event> &dependencies = {})
}
```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event syr(sycl::queue &queue,
                  onemkl::uplo upper_lower,
                  std::int64_t n,
                  T alpha,
                  const T *x,
                  std::int64_t incx,
                  T *a,
                  std::int64_t lda,
                  const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

a Pointer to input matrix A. The array holding input matrix A must have size at least $\text{lda} * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least n, and positive.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

a Pointer to the updated upper triangular part of the symmetric matrix A if `upper_lower=upper` or the updated lower triangular part of the symmetric matrix A if `upper_lower=lower`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

syr2

Computes a rank-2 update of a symmetric matrix.

Description

The syr2 routines compute two scalar-vector-vector product add them and add the result to a matrix, with a symmetric matrix. The operation is defined as:

$$A \leftarrow \alpha * x * y^T + \alpha * y * x^T + A$$

where:

alpha is a scalar,

A is an n-by-n symmetric matrix,

x and y are vectors of length n.

syr2 supports the following precisions.

T
float
double

syr2 (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void syr2(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
              sycl::buffer<T,1> &y,
              std::int64_t incy,
              sycl::buffer<T,1> &a,
              std::int64_t lda)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void syr2(sycl::queue &queue,
              onemkl::uplo upper_lower,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x,
              std::int64_t incx,
```

(continues on next page)

(continued from previous page)

```

    sycl::buffer<T,1> &y,
    std::int64_t incy,
    sycl::buffer<T,1> &a,
    std::int64_t lda)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

n Number of columns of A. Must be at least zero.

alpha Scaling factor for the matrix-vector product.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

y Buffer holding input/output vector y. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride of vector y.

a Buffer holding input matrix A. Must have size at least $\text{lda} * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least n, and positive.

Output Parameters

a Buffer holding the updated upper triangular part of the symmetric matrix A if `upper_lower=upper`, or the updated lower triangular part of the symmetric matrix A if `upper_lower=lower`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Parent topic: *BLAS Level 2 Routines*

tbmv

Computes a matrix-vector product using a triangular band matrix.

Description

The `tbmv` routines compute a matrix-vector product with a triangular band matrix. The operation is defined as:

$$x \leftarrow op(A) * x$$

where:

`op(A)` is one of `op(A) = A`, or `op(A) = AT`, or `op(A) = AH`,

A is an *n*-by-*n* unit or non-unit, upper or lower triangular band matrix, with (*k* + 1) diagonals,

x is a vector of length *n*.

`tbmv` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

tbmv (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void tbmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              std::int64_t k,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void tbmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              std::int64_t k,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Numbers of rows and columns of A. Must be at least zero.

k Number of sub/super-diagonals of the matrix A. Must be at least zero.

a Buffer holding input matrix A. Must have size at least $lda \cdot n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least $(k + 1)$, and positive.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) \cdot \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

Output Parameters

x Buffer holding the updated vector **x**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

tbmv (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event tbmv(sycl::queue &queue,
                    onemkl::uplo upper_lower,

                    const T *a,
                    std::int64_t lda,
                    T *x,
                    std::int64_t incx,
                    const std::vector<sycl::event> &dependencies = {})
}

```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event tbmv(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    onemkl::transpose trans,
                    onemkl::diag unit_nonunit,
                    std::int64_t n,
                    std::int64_t k,
                    const T *a,
                    std::int64_t lda,
                    T *x,
                    std::int64_t incx,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Numbers of rows and columns of A. Must be at least zero.

k Number of sub/super-diagonals of the matrix A. Must be at least zero.

a Pointer to input matrix A. The array holding input matrix A must have size at least $lda*n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least $(k + 1)$, and positive.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

x Pointer to the updated vector x.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Parent topic: *BLAS Level 2 Routines*

tbsv

Solves a system of linear equations whose coefficients are in a triangular band matrix.

Description

The `tbsv` routines solve a system of linear equations whose coefficients are in a triangular band matrix. The operation is defined as:

$$op(A) * x = b$$

where:

`op(A)` is one of `op(A) = A`, or `op(A) = AT`, or `op(A) = AH`,

`A` is an `n`-by-`n` unit or non-unit, upper or lower triangular band matrix, with `(k + 1)` diagonals,

`b` and `x` are vectors of length `n`.

`tbsv` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

tbsv (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void tbsv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              std::int64_t k,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void tbsv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              std::int64_t k,
              sycl::buffer<T,1> &a,

```

(continues on next page)

(continued from previous page)

```

        std::int64_t lda,
        sycl::buffer<T,1> &x,
        std::int64_t incx)
    }

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

k Number of sub/super-diagonals of the matrix A. Must be at least zero.

a Buffer holding input matrix A. Must have size at least $lda * n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least $(k + 1)$, and positive.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) * abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

Output Parameters

x Buffer holding the solution vector x.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

tbsv (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event tbsv(sycl::queue &queue,
                   onemkl::uplo upper_lower,
                   onemkl::transpose trans,
                   onemkl::diag unit_nonunit,
                   std::int64_t n,
                   std::int64_t k,
                   const T *a,
                   std::int64_t lda,
                   T *x,
                   std::int64_t incx,
                   const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event tbsv(sycl::queue &queue,
                   onemkl::uplo upper_lower,
                   onemkl::transpose trans,
                   onemkl::diag unit_nonunit,
                   std::int64_t n,
                   std::int64_t k,
                   const T *a,
                   std::int64_t lda,
                   T *x,
                   std::int64_t incx,
                   const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies op(A), the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of A. Must be at least zero.

k Number of sub/super-diagonals of the matrix A. Must be at least zero.

a Pointer to input matrix A. The array holding input matrix A must have size at least $lda \cdot n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least $(k + 1)$, and positive.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1) \cdot \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

x Pointer to the solution vector **x**.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

tpmv

Computes a matrix-vector product using a triangular packed matrix.

Description

The `tpmv` routines compute a matrix-vector product with a triangular packed matrix. The operation is defined as:

$$x \leftarrow op(A) * x$$

where:

`op(A)` is one of `op(A) = A`, or `op(A) = AT`, or `op(A) = AH`,

`A` is an `n`-by-`n` unit or non-unit, upper or lower triangular band matrix, supplied in packed form,

`x` is a vector of length `n`.

`tpmv` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

tpmv (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void tpmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              sycl::buffer<T,1> &a,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void tpmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              sycl::buffer<T,1> &a,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Numbers of rows and columns of A. Must be at least zero.

a Buffer holding input matrix A. Must have size at least $(n*(n+1))/2$. See *Matrix Storage* for more details.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

Output Parameters

x Buffer holding the updated vector **x**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

                    onemkl::uplo upper_lower,
                    onemkl::transpose trans,
                    onemkl::diag unit_nonunit,
                    std::int64_t n,
                    const T *a,
                    T *x,
                    std::int64_t incx,
                    const std::vector<sycl::event> &dependencies = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Numbers of rows and columns of A. Must be at least zero.

a Pointer to input matrix A. The array holding input matrix A must have size at least $(n*(n+1))/2$. See *Matrix Storage* for more details.

x Pointer to input vector x. The array holding input vector x must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

x Pointer to the updated vector x.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

tpsv

Solves a system of linear equations whose coefficients are in a triangular packed matrix.

Description

The `tpsv` routines solve a system of linear equations whose coefficients are in a triangular packed matrix. The operation is defined as:

$$op(A) * x = b$$

where:

`op(A)` is one of `op(A) = A`, or `op(A) = AT`, or `op(A) = AH`,

`A` is an `n`-by-`n` unit or non-unit, upper or lower triangular band matrix, supplied in packed form,

`b` and `x` are vectors of length `n`.

`tpsv` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

tpsv (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void tpsv(sycl::queue &queue,
             onemkl::uplo upper_lower,
             onemkl::transpose trans,
             onemkl::diag unit_nonunit,
             std::int64_t n,
             std::int64_t k,
             sycl::buffer<T,1> &a,
             sycl::buffer<T,1> &x,
             std::int64_t incx)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void tpsv(sycl::queue &queue,
             onemkl::uplo upper_lower,
             onemkl::transpose trans,
             onemkl::diag unit_nonunit,
             std::int64_t n,
             std::int64_t k,
             sycl::buffer<T,1> &a,
             sycl::buffer<T,1> &x,
             std::int64_t incx)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Numbers of rows and columns of A. Must be at least zero.

a Buffer holding input matrix A. Must have size at least $(n*(n+1))/2$. See *Matrix Storage* for more details.

x Buffer holding the n-element right-hand side vector b. The buffer must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

Output Parameters

x Buffer holding the solution vector x.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

trmv

Computes a matrix-vector product using a triangular matrix.

Description

The `trmv` routines compute a matrix-vector product with a triangular matrix. The operation is defined as:

$$x \leftarrow op(A) * x$$

where:

$op(A)$ is one of $op(A) = A$, or $op(A) = A^T$, or $op(A) = A^H$,

A is an n -by- n unit or non-unit, upper or lower triangular band matrix,

x is a vector of length n .

`trmv` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

trmv (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void trmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void trmv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              sycl::buffer<T,1> &a,
```

(continues on next page)

(continued from previous page)

```

        std::int64_t lda,
        sycl::buffer<T,1> &x,
        std::int64_t incx)
    }

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies op(A), the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Numbers of rows and columns of A. Must be at least zero.

a Buffer holding input matrix A. Must have size at least lda*n. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least n, and positive.

x Buffer holding input vector x. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride of vector x.

Output Parameters

x Buffer holding the updated vector x.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Parent topic: *BLAS Level 2 Routines*

trsv

Solves a system of linear equations whose coefficients are in a triangular matrix.

Description

The `trsv` routines compute a matrix-vector product with a triangular band matrix. The operation is defined as:

$$\text{op}(A) * x = b$$

where:

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A^T$, or $\text{op}(A) = A^H$,

A is an n -by- n unit or non-unit, upper or lower triangular matrix,

b and x are vectors of length n .

`trsv` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

trsv (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void trsv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              std::int64_t k,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void trsv(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              onemkl::diag unit_nonunit,
              std::int64_t n,
              std::int64_t k,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &x,
              std::int64_t incx)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Numbers of rows and columns of A. Must be at least zero.

a Buffer holding input matrix A. Must have size at least $lda*n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least n, and positive.

x Buffer holding the n-element right-hand side vector b. The buffer must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

Output Parameters

x Buffer holding the solution vector **x**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

trsv (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event trsv(sycl::queue &queue,
                   onemkl::uplo upper_lower,
                   onemkl::transpose trans,
                   onemkl::diag unit_nonunit,
                   std::int64_t n,
                   std::int64_t k,
                   const T *a,
                   std::int64_t lda,
                   T *x,
                   std::int64_t incx,
                   const std::vector<sycl::event> &dependencies = {})
}

```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event trsv(sycl::queue &queue,
                   onemkl::uplo upper_lower,
                   onemkl::transpose trans,
                   onemkl::diag unit_nonunit,
                   std::int64_t n,
                   std::int64_t k,
                   const T *a,
                   std::int64_t lda,
                   T *x,
                   std::int64_t incx,
                   const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies op(A), the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_nonunit Specifies whether the matrix A is unit triangular or not. See *oneMKL defined datatypes* for more details.

n Numbers of rows and columns of A. Must be at least zero.

a Pointer to input matrix A. The array holding input matrix A must have size at least $lda*n$. See *Matrix Storage* for more details.

lda Leading dimension of matrix A. Must be at least n, and positive.

x Pointer to the n-element right-hand side vector b. The array holding the n-element right-hand side vector b must be of size at least $(1 + (n - 1)*abs(incx))$. See *Matrix Storage* for more details.

incx Stride of vector x.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

x Pointer to the solution vector x.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 2 Routines*

Parent topic: *BLAS Routines*

BLAS Level 3 Routines

BLAS Level 3 includes routines which perform matrix-matrix operations as described in the following table.

Routines	Description
<i>gemm</i>	Computes a matrix-matrix product with general matrices.
<i>hemm</i>	Computes a matrix-matrix product where one input matrix is Hermitian and one is general.
<i>herk</i>	Performs a Hermitian rank-k update.
<i>her2k</i>	Performs a Hermitian rank-2k update.
<i>symm</i>	Computes a matrix-matrix product where one input matrix is symmetric and one matrix is general.
<i>syrk</i>	Performs a symmetric rank-k update.
<i>syr2k</i>	Performs a symmetric rank-2k update.
<i>trmm</i>	Computes a matrix-matrix product where one input matrix is triangular and one input matrix is general.
<i>trsm</i>	Solves a triangular matrix equation (forward or backward solve).

gemm

Computes a matrix-matrix product with general matrices.

Description

The *gemm* routines compute a scalar-matrix-matrix product and add the result to a scalar-matrix product, with general matrices. The operation is defined as:

$$C \leftarrow \alpha * op(A) * op(B) + \beta * C$$

where:

$op(X)$ is one of $op(X) = X$, or $op(X) = X^T$, or $op(X) = X^H$,

α and β are scalars,

A, B and C are matrices,

$op(A)$ is an m-by-k matrix,

$op(B)$ is a k-by-n matrix,

C is an m-by-n matrix.

gemm supports the following precisions.

Ta (A matrix)	Tb (B matrix)	Tc (C matrix)	Ts (alpha/beta)
std::int8_t	std::int8_t	std::int32_t	float
std::int8_t	std::int8_t	float	float
half	half	float	float
half	half	half	half
bfloat16	bfloat16	float	float
bfloat16	bfloat16	bfloat16	float
float	float	float	float
double	double	double	double
std::complex<float>	std::complex<float>	std::complex<float>	std::complex<float>
std::complex<double>	std::complex<double>	std::complex<double>	std::complex<double>

gemm (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void gemm(sycl::queue &queue,
              onemkl::transpose transa,
              onemkl::transpose transb,
              std::int64_t m,
              std::int64_t n,
              std::int64_t k,
              Ts alpha,
              sycl::buffer<Ta,1> &a,
              std::int64_t lda,
              sycl::buffer<Tb,1> &b,
              std::int64_t ldb,
              Ts beta,
              sycl::buffer<Tc,1> &c,
              std::int64_t ldc)
}

```

```
namespace oneapi::mkl::blas::row_major {
    void gemm(sycl::queue &queue,
              onemkl::transpose transa,
              onemkl::transpose transb,
              std::int64_t m,
              std::int64_t n,
              std::int64_t k,
              Ts alpha,
              sycl::buffer<Ta,1> &a,
              std::int64_t lda,
              sycl::buffer<Tb,1> &b,
              std::int64_t ldb,
              Ts beta,

```

(continues on next page)

(continued from previous page)

```

sycl::buffer<Tc,1> &c,
std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies the form of $\text{op}(A)$, the transposition operation applied to A.

transb Specifies the form of $\text{op}(B)$, the transposition operation applied to B.

m Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C. The value of m must be at least zero.

n Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C. The value of n must be at least zero.

k Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of k must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a The buffer holding the input matrix A.

	A not transposed	A transposed
Column major	A is an m-by-k matrix so the array a must have size at least $\text{lda} * k$.	A is an k-by-m matrix so the array a must have size at least $\text{lda} * m$
Row major	A is an m-by-k matrix so the array a must have size at least $\text{lda} * m$.	A is an k-by-m matrix so the array a must have size at least $\text{lda} * k$

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least m.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least m.

b The buffer holding the input matrix B.

	B not transposed	B transposed
Column major	B is an k-by-n matrix so the array b must have size at least $\text{ldb} * n$.	B is an n-by-k matrix so the array b must have size at least $\text{ldb} * k$
Row major	B is an k-by-n matrix so the array b must have size at least $\text{ldb} * k$.	B is an n-by-k matrix so the array b must have size at least $\text{ldb} * n$

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least k.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least k.

beta Scaling factor for matrix C.

c The buffer holding the input/output matrix C. It must have a size of at least $ldc*n$ if column major layout is used to store matrices or at least $ldc*m$ if row major layout is used to store matrices. See [Matrix Storage](#) for more details.

ldc The leading dimension of C. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

Output Parameters

c The buffer, which is overwritten by $\alpha*op(A)*op(B) + \beta*C$.

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `gemm`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

gemm (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event gemm(sycl::queue &queue,
                   onemkl::transpose transa,
                   onemkl::transpose transb,
                   std::int64_t m,
                   std::int64_t n,
                   std::int64_t k,
                   Ts alpha,
                   const Ta *a,
                   std::int64_t lda,
                   const Tb *b,
                   std::int64_t ldb,
                   Ts beta,
                   Tc *c,
                   std::int64_t ldc,
                   const std::vector<sycl::event> &dependencies = {})
}
```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event gemm(sycl::queue &queue,

                    onemkl::transpose transb,
                    std::int64_t m,
                    std::int64_t n,
                    std::int64_t k,
                    Ts alpha,
                    const Ta *a,
                    std::int64_t lda,
                    const Tb *b,
                    std::int64_t ldb,
                    Ts beta,
                    Tc *c,
                    std::int64_t ldc,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies the form of $op(A)$, the transposition operation applied to A.

transb Specifies the form of $op(B)$, the transposition operation applied to B.

m Specifies the number of rows of the matrix $op(A)$ and of the matrix C. The value of m must be at least zero.

n Specifies the number of columns of the matrix $op(B)$ and the number of columns of the matrix C. The value of n must be at least zero.

k Specifies the number of columns of the matrix $op(A)$ and the number of rows of the matrix $op(B)$. The value of k must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Pointer to input matrix A.

	A not transposed	A transposed
Column major	A is an m-by-k matrix so the array a must have size at least $lda*k$.	A is an k-by-m matrix so the array a must have size at least $lda*m$
Row major	A is an m-by-k matrix so the array a must have size at least $lda*m$.	A is an k-by-m matrix so the array a must have size at least $lda*k$

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least m.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least m.

b Pointer to input matrix B.

	B not transposed	B transposed
Column major	B is an k-by-n matrix so the array b must have size at least $ldb*n$.	B is an n-by-k matrix so the array b must have size at least $ldb*k$
Row major	B is an k-by-n matrix so the array b must have size at least $ldb*k$.	B is an n-by-k matrix so the array b must have size at least $ldb*n$

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least k.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least k.

beta Scaling factor for matrix C.

c The pointer to input/output matrix C. It must have a size of at least $ldc*n$ if column major layout is used to store matrices or at least $ldc*m$ if row major layout is used to store matrices . See *Matrix Storage* for more details.

ldc The leading dimension of C. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Pointer to the output matrix, overwritten by $\alpha*op(A)*op(B) + \beta*C$.

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `gemm`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 3 Routines*

hemm

Computes a matrix-matrix product where one input matrix is Hermitian and one is general.

Description

The `hemm` routines compute a scalar-matrix-matrix product and add the result to a scalar-matrix product, where one of the matrices in the multiplication is Hermitian. The argument `left_right` determines if the Hermitian matrix, `A`, is on the left of the multiplication (`left_right = side::left`) or on the right (`left_right = side::right`). Depending on `left_right`, the operation is defined as:

$$C \leftarrow \alpha * A * B + \beta * C$$

or

$$C \leftarrow \alpha * B * A + \beta * C$$

where:

`alpha` and `beta` are scalars,

`A` is a Hermitian matrix, either `m`-by-`m` or `n`-by-`n` matrices,

`B` and `C` are `m`-by-`n` matrices.

`hemm` supports the following precisions:

T
<code>std::complex<float></code>
<code>std::complex<double></code>

hemm (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void hemm(sycl::queue &queue,
              onemkl::side left_right,
              onemkl::uplo upper_lower,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb,
              T beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void hemm(sycl::queue &queue,
              onemkl::side left_right,
              onemkl::uplo upper_lower,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb,
              T beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether *A* is on the left side of the multiplication (`side::left`) or on the right side (`side::right`). See *oneMKL defined datatypes* for more details.

uplo Specifies whether *A*'s data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

m Specifies the number of rows of the matrix *B* and *C*.

The value of *m* must be at least zero.

n Specifies the number of columns of the matrix *B* and *C*.

The value of *n* must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Buffer holding input matrix *A*. Must have size at least $lda * m$ if *A* is on the left of the multiplication, or $lda * n$ if *A* is on the right. See *Matrix Storage* for more details.

lda Leading dimension of *A*. Must be at least *m* if *A* is on the left of the multiplication, or at least *n* if *A* is on the right. Must be positive.

b Buffer holding input matrix *B*. Must have size at least $ldb * n$ if column major layout is used to store matrices or at least $ldb * m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldb Leading dimension of *B*. It must be positive and at least *m* if column major layout is used to store matrices or at least *n* if row major layout is used to store matrices.

beta Scaling factor for matrix *C*.

c The buffer holding the input/output matrix *C*. It must have a size of at least $ldc * n$ if column major layout is used to store matrices or at least $ldc * m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldc The leading dimension of *C*. It must be positive and at least *m* if column major layout is used to store matrices or at least *n* if row major layout is used to store matrices.

Output Parameters

c Output buffer, overwritten by $\alpha * A * B + \beta * C$ (`left_right = side::left`) or $\alpha * B * A + \beta * C$ (`left_right = side::right`).

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `hemm`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether A is on the left side of the multiplication (`side::left`) or on the right side (`side::right`). See *oneMKL defined datatypes* for more details.

uplo Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

m Specifies the number of rows of the matrix B and C.

The value of **m** must be at least zero.

n Specifies the number of columns of the matrix B and C.

The value of **n** must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Pointer to input matrix A. Must have size at least $lda \cdot m$ if A is on the left of the multiplication, or $lda \cdot n$ if A is on the right. See *Matrix Storage* for more details.

lda Leading dimension of A. Must be at least **m** if A is on the left of the multiplication, or at least **n** if A is on the right. Must be positive.

b Pointer to input matrix B. Must have size at least $ldb \cdot n$ if column major layout is used to store matrices or at least $ldb \cdot m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldb Leading dimension of B. It must be positive and at least **m** if column major layout is used to store matrices or at least **n** if row major layout is used to store matrices.

beta Scaling factor for matrix C.

c The pointer to input/output matrix C. It must have a size of at least $ldc \cdot n$ if column major layout is used to store matrices or at least $ldc \cdot m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldc The leading dimension of C. It must be positive and at least **m** if column major layout is used to store matrices or at least **n** if row major layout is used to store matrices.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Pointer to the output matrix, overwritten by $\alpha * A * B + \beta * C$ (`left_right = side::left`) or $\alpha * B * A + \beta * C$ (`left_right = side::right`).

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `hemm`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

herk

Performs a Hermitian rank-k update.

Description

The `herk` routines compute a rank-k update of a Hermitian matrix C by a general matrix A. The operation is defined as:

$$C \leftarrow \alpha * op(A) * op(A)^H + \beta * C$$

where:

`op(X)` is one of `op(X) = X` or `op(X) = XH`,

`alpha` and `beta` are real scalars,

C is a Hermitian matrix and A is a general matrix.

Here `op(A)` is `n x k`, and C is `n x n`.

`herk` supports the following precisions:

T	Treal
<code>std::complex<float></code>	float
<code>std::complex<double></code>	double

herk (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void herk(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              std::int64_t n,
              std::int64_t k,
              Treal alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              Treal beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void herk(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              std::int64_t n,
              std::int64_t k,
              Treal alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              Treal beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details. Supported operations are `transpose::nontrans` and `transpose::conjtrans`.

n The number of rows and columns in C. The value of n must be at least zero.

k Number of columns in $op(A)$.

The value of k must be at least zero.

alpha Real scaling factor for the rank-k update.

a Buffer holding input matrix A.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	A is an n-by-k matrix so the array a must have size at least lda*k.	A is a k-by-n matrix so the array a must have size at least lda*n
Row major	A is an n-by-k matrix so the array a must have size at least lda*n.	A is an k-by-n matrix so the array a must have size at least lda*k.

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	lda must be at least n.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least n.

beta Real scaling factor for matrix C.

c Buffer holding input/output matrix C. Must have size at least ldc*n. See *Matrix Storage* for more details.

ldc Leading dimension of C. Must be positive and at least n.

Output Parameters

c The output buffer, overwritten by $\alpha * \text{op}(A) * \text{op}(A)^T + \beta * C$. The imaginary parts of the diagonal elements are set to zero.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

herk (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event herk(sycl::queue &queue,
                   onemkl::uplo upper_lower,
                   onemkl::transpose trans,
                   std::int64_t n,
                   std::int64_t k,
```

    T *c,
    std::int64_t ldc,
    const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event herk(sycl::queue &queue,
        onemkl::uplo upper_lower,
        onemkl::transpose trans,
        std::int64_t n,
        std::int64_t k,
        Treal alpha,
        const T *a,
        std::int64_t lda,
        Treal beta,
        T *c,
        std::int64_t ldc,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details. Supported operations are `transpose::nontrans` and `transpose::conjtrans`.

n The number of rows and columns in C. The value of n must be at least zero.

k Number of columns in $op(A)$.

The value of k must be at least zero.

alpha Real scaling factor for the rank-k update.

a Pointer to input matrix A.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> OR <code>transpose::conjtrans</code>
Column major	A is an n-by-k matrix so the array a must have size at least $lda*k$.	A is an k-by-n matrix so the array a must have size at least $lda*n$.
Row major	A is an n-by-k matrix so the array a must have size at least $lda*n$.	A is an k-by-n matrix so the array a must have size at least $lda*k$.

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	trans transpose::nontrans	=	trans = transpose::trans transpose::conjtrans	or
Column major	lda must be at least n.		lda must be at least k.	
Row major	lda must be at least k.		lda must be at least n.	

beta Real scaling factor for matrix C.

c Pointer to input/output matrix C. Must have size at least $ldc*n$. See *Matrix Storage* for more details.

ldc Leading dimension of C. Must be positive and at least n.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Pointer to the output matrix, overwritten by $\alpha*op(A)*op(A)^T + \beta*C$. The imaginary parts of the diagonal elements are set to zero.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 3 Routines*

her2k

Performs a Hermitian rank-2k update.

Description

The `her2k` routines perform a rank-2k update of an $n \times n$ Hermitian matrix C by general matrices A and B .

If `trans = transpose::nontrans`, the operation is defined as:

$$C \leftarrow \alpha * A * B^H + \text{conjg}(\alpha) * B * A^H + \text{beta} * C$$

where A is $n \times k$ and B is $k \times n$.

If `trans = transpose::conjtrans`, the operation is defined as:

$$C \leftarrow \alpha * B * A^H + \text{conjg}(\alpha) * A * B^H + \text{beta} * C$$

where A is $k \times n$ and B is $n \times k$.

In both cases:

`alpha` is a complex scalar and `beta` is a real scalar.

C is a Hermitian matrix and A , B are general matrices.

The inner dimension of both matrix multiplications is k .

`her2k` supports the following precisions:

T	Treal
<code>std::complex<float></code>	float
<code>std::complex<double></code>	double

her2k (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void her2k(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              std::int64_t n,
              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb,
              Treal beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void her2k(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              std::int64_t n,
```

(continues on next page)

(continued from previous page)

```

std::int64_t k,
T alpha,
sycl::buffer<T,1> &a,
std::int64_t lda,
sycl::buffer<T,1> &b,
std::int64_t ldb,
Treal beta,
sycl::buffer<T,1> &c,
std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

trans Specifies the operation to apply, as described above. Supported operations are `transpose::nontrans` and `transpose::conjtrans`.

n The number of rows and columns in C. The value of **n** must be at least zero.

k The inner dimension of matrix multiplications. The value of **k** must be at least equal to zero.

alpha Complex scaling factor for the rank-2k update.

a Buffer holding input matrix A.

	trans = transpose::nontrans	trans = transpose::trans or transpose::conjtrans
Column major	A is an n-by-k matrix so the array a must have size at least lda*k.	A is an k-by-n matrix so the array a must have size at least lda*n
Row major	A is an n-by-k matrix so the array a must have size at least lda*n.	A is an k-by-n matrix so the array a must have size at least lda*k.

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	trans = transpose::nontrans	trans = transpose::trans or transpose::conjtrans
Column major	lda must be at least n.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least n.

b Buffer holding input matrix B.

	trans = transpose::nontrans	trans = transpose::trans or transpose::conjtrans
Column major	B is an k-by-n matrix so the array b must have size at least ldb*n.	B is an n-by-k matrix so the array b must have size at least ldb*k
Row major	B is an k-by-n matrix so the array b must have size at least ldb*k.	B is an n-by-k matrix so the array b must have size at least ldb*n.

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	trans transpose::nontrans	=	trans = transpose::trans transpose::conjtrans	or
Column major	ldb must be at least k.		ldb must be at least n.	
Row major	ldb must be at least n.		ldb must be at least k.	

beta Real scaling factor for matrix C.

c Buffer holding input/output matrix C. Must have size at least $ldb * n$. See *Matrix Storage* for more details.

ldc Leading dimension of C. Must be positive and at least n.

Output Parameters

c Output buffer, overwritten by the updated C matrix.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

her2k (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event her2k(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    onemkl::transpose trans,
                    std::int64_t n,
                    std::int64_t k,
                    T alpha,
                    const T *a,
                    std::int64_t lda,
                    const T *b,
                    std::int64_t ldb,
                    Treal beta,
                    T *c,
                    std::int64_t ldc,
```

        Treal beta,
        T *c,
        std::int64_t ldc,
        const std::vector<sycl::event> &dependencies = {}
    )
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A’s data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

trans Specifies the operation to apply, as described above. Supported operations are `transpose::nontrans` and `transpose::conjtrans`.

n The number of rows and columns in C. The value of n must be at least zero.

k The inner dimension of matrix multiplications. The value of k must be at least equal to zero.

alpha Complex scaling factor for the rank-2k update.

a Pointer to input matrix A.

	trans = transpose::nontrans	trans = transpose::trans Or transpose::conjtrans
Column major	A is an n-by-k matrix so the array a must have size at least lda*k.	A is a k-by-n matrix so the array a must have size at least lda*n
Row major	A is an n-by-k matrix so the array a must have size at least lda*n.	A is a k-by-n matrix so the array a must have size at least lda*k.

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	trans = transpose::nontrans	trans = transpose::trans Or transpose::conjtrans
Column major	lda must be at least n.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least n.

b Pointer to input matrix B.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	B is a k-by-n matrix so the array b must have size at least <code>ldb*n</code> .	B is an n-by-k matrix so the array b must have size at least <code>ldb*k</code>
Row major	B is a k-by-n matrix so the array b must have size at least <code>ldb*k</code> .	B is an n-by-k matrix so the array b must have size at least <code>ldb*n</code> .

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	<code>ldb</code> must be at least k.	<code>ldb</code> must be at least n.
Row major	<code>ldb</code> must be at least n.	<code>ldb</code> must be at least k.

beta Real scaling factor for matrix C.

c Pointer to input/output matrix C. Must have size at least `ldc*n`. See *Matrix Storage* for more details.

ldc Leading dimension of C. Must be positive and at least n.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Pointer to the output matrix, overwritten by the updated C matrix.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::invalid_argument`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

Parent topic: *BLAS Level 3 Routines*

symm

Computes a matrix-matrix product where one input matrix is symmetric and one matrix is general.

Description

The `symm` routines compute a scalar-matrix-matrix product and add the result to a scalar-matrix product, where one of the matrices in the multiplication is symmetric. The argument `left_right` determines if the symmetric matrix, `A`, is on the left of the multiplication (`left_right = side::left`) or on the right (`left_right = side::right`). Depending on `left_right`, the operation is defined as:

$$C \leftarrow \alpha * A * B + \beta * C$$

or

$$C \leftarrow \alpha * B * A + \beta * C$$

where:

`alpha` and `beta` are scalars,

`A` is a symmetric matrix, either `m`-by-`m` or `n`-by-`n`,

`B` and `C` are `m`-by-`n` matrices.

`symm` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

symm (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void symm(sycl::queue &queue,
              onemkl::side left_right,
              onemkl::uplo upper_lower,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb,
              T beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void symm(sycl::queue &queue,
              onemkl::side left_right,
              onemkl::uplo upper_lower,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb,
              T beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether A is on the left side of the multiplication (`side::left`) or on the right side (`side::right`). See *oneMKL defined datatypes* for more details.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

m Number of rows of B and C. The value of m must be at least zero.

n Number of columns of B and C. The value of n must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Buffer holding input matrix A. Must have size at least $lda*m$ if A is on the left of the multiplication, or $lda*n$ if A is on the right. See *Matrix Storage* for more details.

lda Leading dimension of A. Must be at least m if A is on the left of the multiplication, or at least n if A is on the right. Must be positive.

b Buffer holding input matrix B. Must have size at least $ldb*n$ if column major layout is used to store matrices or at least $ldb*m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldb Leading dimension of B. It must be positive and at least m if column major layout is used to store matrices or at least n if column major layout is used to store matrices.

beta Scaling factor for matrix C.

c The buffer holding the input/output matrix C. It must have a size of at least $ldc*n$ if column major layout is used to store matrices or at least $ldc*m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldc The leading dimension of C. It must be positive and at least m if column major layout is used to store matrices or at least n if column major layout is used to store matrices.

Output Parameters

c Output buffer, overwritten by $\alpha * A * B + \beta * C$ (`left_right = side::left`) or $\alpha * B * A + \beta * C$ (`left_right = side::right`).

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `symm`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

symm (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {

}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether A is on the left side of the multiplication (`side::left`) or on the right side (`side::right`). See *oneMKL defined datatypes* for more details.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

m Number of rows of B and C. The value of m must be at least zero.

n Number of columns of B and C. The value of n must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Pointer to input matrix A. Must have size at least $lda \cdot m$ if A is on the left of the multiplication, or $lda \cdot n$ if A is on the right. See *Matrix Storage* for more details.

lda Leading dimension of A. Must be at least m if A is on the left of the multiplication, or at least n if A is on the right. Must be positive.

b Pointer to input matrix B. Must have size at least $ldb \cdot n$ if column major layout is used to store matrices or at least $ldb \cdot m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldb Leading dimension of B. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

beta Scaling factor for matrix C.

c The pointer to input/output matrix C. It must have a size of at least $ldc \cdot n$ if column major layout is used to store matrices or at least $ldc \cdot m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldc The leading dimension of C. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Pointer to the output matrix, overwritten by $\alpha \cdot A \cdot B + \beta \cdot C$ (`left_right = side::left`) or $\alpha \cdot B \cdot A + \beta \cdot C$ (`left_right = side::right`).

Notes

If `beta = 0`, matrix `C` does not need to be initialized before calling `symm`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 3 Routines*

syrk

Performs a symmetric rank-k update.

Description

The `syrrk` routines perform a rank-k update of a symmetric matrix `C` by a general matrix `A`. The operation is defined as:

$$C \leftarrow \alpha * \text{op}(A) * \text{op}(A)^T + \beta * C$$

where:

`op(X)` is one of `op(X) = X` or `op(X) = XT`,

`alpha` and `beta` are scalars,

`C` is a symmetric matrix and `A` is a general matrix.

Here `op(A)` is `n-by-k`, and `C` is `n-by-n`.

`syrrk` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

syrk (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void syrk(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              std::int64_t n,
              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              T beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void syrk(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              std::int64_t n,
              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              T beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A (See *oneMKL defined datatypes* for more details). Conjugation is never performed, even if `trans = transpose::conjtrans`.

n Number of rows and columns in C. The value of n must be at least zero.

k Number of columns in $op(A)$. The value of k must be at least zero.

alpha Scaling factor for the rank-k update.

a Buffer holding input matrix A.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	A is an n-by-k matrix so the array a must have size at least <code>lda*k</code> .	A is a k-by-n matrix so the array a must have size at least <code>lda*n</code>
Row major	A is an n-by-k matrix so the array a must have size at least <code>lda*n</code> .	A is a k-by-n matrix so the array a must have size at least <code>lda*k</code> .

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	<code>lda</code> must be at least n.	<code>lda</code> must be at least k.
Row major	<code>lda</code> must be at least k.	<code>lda</code> must be at least n.

beta Scaling factor for matrix C.

c Buffer holding input/output matrix C. Must have size at least `ldc*n`. See *Matrix Storage* for more details.

ldc Leading dimension of C. Must be positive and at least n.

Output Parameters

c Output buffer, overwritten by $\alpha * \text{op}(A) * \text{op}(A)^T + \text{beta} * C$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

syrk (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event syrk(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    onemkl::transpose trans,
                    std::int64_t n,
                    std::int64_t k,
                    T alpha,
```

(continues on next page)

(continued from previous page)

```

    const T *a,
    std::int64_t lda,
    T beta,
    T *c,
    std::int64_t ldc,

}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event syrks(sycl::queue &queue,
        onemkl::uplo upper_lower,
        onemkl::transpose trans,
        std::int64_t n,
        std::int64_t k,
        T alpha,
        const T *a,
        std::int64_t lda,
        T beta,
        T *c,
        std::int64_t ldc,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A (See *oneMKL defined datatypes* for more details). Conjugation is never performed, even if `trans = transpose::conjtrans`.

n Number of rows and columns in C. The value of n must be at least zero.

k Number of columns in $op(A)$. The value of k must be at least zero.

alpha Scaling factor for the rank-k update.

a Pointer to input matrix A.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> Or <code>transpose::conjtrans</code>
Column major	A is an n-by-k matrix so the array a must have size at least <code>lda*k</code> .	A is an k-by-n matrix so the array a must have size at least <code>lda*n</code>
Row major	A is an n-by-k matrix so the array a must have size at least <code>lda*n</code> .	A is an k-by-n matrix so the array a must have size at least <code>lda*k</code> .

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	trans transpose::nontrans	=	trans = transpose::trans transpose::conjtrans	or
Column major	lda must be at least n.		lda must be at least k.	
Row major	lda must be at least k.		lda must be at least n.	

beta Scaling factor for matrix C.

c Pointer to input/output matrix C. Must have size at least ldc*n. See *Matrix Storage* for more details.

ldc Leading dimension of C. Must be positive and at least n.

Output Parameters

c Pointer to the output matrix, overwritten by $\alpha * \text{op}(A) * \text{op}(A)^T + \text{beta} * C$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 3 Routines*

syr2k

Performs a symmetric rank-2k update.

Description

The syr2k routines perform a rank-2k update of an n x n symmetric matrix C by general matrices A and B.

If trans = transpose::nontrans, the operation is defined as:

$$C \leftarrow \alpha * (A * B^T + B * A^T) + \text{beta} * C$$

where A and B are n x k matrices.

If trans = transpose::trans, the operation is defined as:

$$C \leftarrow \alpha * (A^T * B + B^T * A) + \text{beta} * C$$

where A and B are $k \times n$ matrices.

In both cases:

alpha and beta are scalars,

C is a symmetric matrix and A,B are general matrices,

The inner dimension of both matrix multiplications is k.

syr2k supports the following precisions:

T
float
double
std::complex<float>
std::complex<double>

syr2k (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void syr2k(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              std::int64_t n,
              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb,
              T beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

```
namespace oneapi::mkl::blas::row_major {
    void syr2k(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose trans,
              std::int64_t n,
              std::int64_t k,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb,
              T beta,
              sycl::buffer<T,1> &c,
              std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

trans Specifies the operation to apply, as described above. Conjugation is never performed, even if `trans = transpose::conjtrans`.

n Number of rows and columns in C. The value of `n` must be at least zero.

k Inner dimension of matrix multiplications. The value of `k` must be at least zero.

alpha Scaling factor for the rank-2k update.

a Buffer holding input matrix A.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	A is an n-by-k matrix so the array a must have size at least <code>lda*k</code> .	A is a k-by-n matrix so the array a must have size at least <code>lda*n</code>
Row major	A is an n-by-k matrix so the array a must have size at least <code>lda*n</code> .	A is an k-by-n matrix so the array a must have size at least <code>lda*k</code> .

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	<code>lda</code> must be at least <code>n</code> .	<code>lda</code> must be at least <code>k</code> .
Row major	<code>lda</code> must be at least <code>k</code> .	<code>lda</code> must be at least <code>n</code> .

b Buffer holding input matrix B.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	B is an n-by-k matrix so the array b must have size at least <code>ldb*k</code> .	B is a k-by-n matrix so the array b must have size at least <code>ldb*n</code>
Row major	B is an n-by-k matrix so the array b must have size at least <code>ldb*n</code> .	B is an k-by-n matrix so the array b must have size at least <code>ldb*k</code> .

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	<code>ldb</code> must be at least <code>n</code> .	<code>ldb</code> must be at least <code>k</code> .
Row major	<code>ldb</code> must be at least <code>k</code> .	<code>ldb</code> must be at least <code>n</code> .

beta Scaling factor for matrix C.

c Buffer holding input/output matrix C. Must have size at least $ldc*n$. See *Matrix Storage* for more details

ldc Leading dimension of C. Must be positive and at least n.

Output Parameters

c Output buffer, overwritten by the updated C matrix.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether A's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

trans Specifies the operation to apply, as described above. Conjugation is never performed, even if `trans = transpose::conjtrans`.

n Number of rows and columns in C. The value of `n` must be at least zero.

k Inner dimension of matrix multiplications. The value of `k` must be at least zero.

alpha Scaling factor for the rank-2k update.

a Pointer to input matrix A.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	A is an n-by-k matrix so the array a must have size at least <code>lda*k</code> .	A is an k-by-n matrix so the array a must have size at least <code>lda*n</code>
Row major	A is an n-by-k matrix so the array a must have size at least <code>lda*n</code> .	A is an k-by-n matrix so the array a must have size at least <code>lda*k</code> .

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	<code>lda</code> must be at least <code>n</code> .	<code>lda</code> must be at least <code>k</code> .
Row major	<code>lda</code> must be at least <code>k</code> .	<code>lda</code> must be at least <code>n</code> .

b Pointer to input matrix B.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>transpose::conjtrans</code>
Column major	B is an n-by-k matrix so the array b must have size at least <code>ldb*k</code> .	B is an k-by-n matrix so the array b must have size at least <code>ldb*n</code>
Row major	B is an n-by-k matrix so the array b must have size at least <code>ldb*n</code> .	B is an k-by-n matrix so the array b must have size at least <code>ldb*k</code> .

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	trans transpose::nontrans	=	trans = transpose::trans transpose::conjtrans	or
Column major	ldb must be at least n.		ldb must be at least k.	
Row major	ldb must be at least k.		ldb must be at least n.	

beta Scaling factor for matrix C.

c Pointer to input/output matrix C. Must have size at least $ldb * n$. See *Matrix Storage* for more details

ldc Leading dimension of C. Must be positive and at least n.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Pointer to the output matrix, overwritten by the updated C matrix.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 3 Routines*

trmm

Computes a matrix-matrix product where one input matrix is triangular and one input matrix is general.

Description

The `trmm` routines compute a scalar-matrix-matrix product where one of the matrices in the multiplication is triangular. The argument `left_right` determines if the triangular matrix, `A`, is on the left of the multiplication (`left_right = side::left`) or on the right (`left_right = side::right`). Depending on `left_right`. The operation is defined as:

$$B \leftarrow \alpha * op(A) * B$$

or

$$B \leftarrow \alpha * B * op(A)$$

where:

`op(A)` is one of `op(A) = A`, or `op(A) = AT`, or `op(A) = AH`,

`alpha` is a scalar,

`A` is a triangular matrix, and `B` is a general matrix.

Here `B` is `m x n` and `A` is either `m x m` or `n x n`, depending on `left_right`.

`trmm` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

trmm (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void trmm(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose transa,
              onemkl::diag unit_diag,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void trmm(sycl::queue &queue,
              onemkl::uplo upper_lower,
              onemkl::transpose transa,
              onemkl::diag unit_diag,
```

(continues on next page)

(continued from previous page)

```

    std::int64_t m,
    std::int64_t n,
    T alpha,
    sycl::buffer<T,1> &a,
    std::int64_t lda,
    sycl::buffer<T,1> &b,
    std::int64_t ldb)
}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether A is on the left side of the multiplication (`side::left`) or on the right side (`side::right`). See *oneMKL defined datatypes* for more details.

uplo Specifies whether the matrix A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies `op(A)`, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_diag Specifies whether A is assumed to be unit triangular (all diagonal elements are 1). See *oneMKL defined datatypes* for more details.

m Specifies the number of rows of B. The value of m must be at least zero.

n Specifies the number of columns of B. The value of n must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Buffer holding input matrix A. Must have size at least `lda*m` if `left_right = side::left`, or `lda*n` if `left_right = side::right`. See *Matrix Storage* for more details.

lda Leading dimension of A. Must be at least m if `left_right = side::left`, and at least n if `left_right = side::right`. Must be positive.

b Buffer holding input/output matrix B. Must have size at least `ldb*n` if column major layout is used to store matrices or at least `ldb*m` if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldb Leading dimension of B. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

Output Parameters

b Output buffer, overwritten by `alpha*op(A)*B` or `alpha*B*op(A)`.

Notes

If `alpha = 0`, matrix B is set to zero, and A and B do not need to be initialized at entry.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

                    T *b,
                    std::int64_t ldb,
                    const std::vector<sycl::event> &dependencies = {})
}

```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event trmm(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    onemkl::transpose transa,
                    onemkl::diag unit_diag,
                    std::int64_t m,
                    std::int64_t n,
                    T alpha,
                    const T *a,
                    std::int64_t lda,
                    T *b,
                    std::int64_t ldb,
                    const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether A is on the left side of the multiplication (`side::left`) or on the right side (`side::right`). See *oneMKL defined datatypes* for more details.

uplo Specifies whether the matrix A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies `op(A)`, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_diag Specifies whether A is assumed to be unit triangular (all diagonal elements are 1). See *oneMKL defined datatypes* for more details.

m Specifies the number of rows of B. The value of m must be at least zero.

n Specifies the number of columns of B. The value of n must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Pointer to input matrix A. Must have size at least `lda*m` if `left_right = side::left`, or `lda*n` if `left_right = side::right`. See *Matrix Storage* for more details.

lda Leading dimension of A. Must be at least m if `left_right = side::left`, and at least n if `left_right = side::right`. Must be positive.

b Pointer to input/output matrix B. Must have size at least `ldb*n` if column major layout is used to store matrices or at least `ldb*m` if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldb Leading dimension of B. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

b Pointer to the output matrix, overwritten by `alpha*op(A)*B` or `alpha*B*op(A)`.

Notes

If `alpha = 0`, matrix B is set to zero, and A and B do not need to be initialized at entry.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS Level 3 Routines*

trsm

Solves a triangular matrix equation (forward or backward solve).

Description

The `trsm` routines solve one of the following matrix equations:

$$op(A) * X = alpha * B$$

or

$$X * op(A) = alpha * B$$

where:

`op(A)` is one of `op(A) = A`, or `op(A) = AT`, or `op(A) = AH`,

`alpha` is a scalar,

`A` is a triangular matrix, and

`B` and `X` are `m x n` general matrices.

`A` is either `m x m` or `n x n`, depending on whether it multiplies `X` on the left or right. On return, the matrix `B` is overwritten by the solution matrix `X`.

`trsm` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

trsm (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void trsm(sycl::queue &queue,
              onemkl::side left_right,
              onemkl::uplo upper_lower,
              onemkl::transpose transa,
              onemkl::diag unit_diag,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
```

(continues on next page)

(continued from previous page)

```

        std::int64_t ldb)
    }

```

```

namespace oneapi::mkl::blas::row_major {
    void trsm(sycl::queue &queue,
              onemkl::side left_right,
              onemkl::uplo upper_lower,
              onemkl::transpose transa,
              onemkl::diag unit_diag,
              std::int64_t m,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &a,
              std::int64_t lda,
              sycl::buffer<T,1> &b,
              std::int64_t ldb)
}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether A multiplies X on the left (`side::left`) or on the right (`side::right`). See *oneMKL defined datatypes* for more details.

uplo Specifies whether the matrix A is upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

unit_diag Specifies whether A is assumed to be unit triangular (all diagonal elements are 1). See *oneMKL defined datatypes* for more details.

m Specifies the number of rows of B. The value of m must be at least zero.

n Specifies the number of columns of B. The value of n must be at least zero.

alpha Scaling factor for the solution.

a Buffer holding input matrix A. Must have size at least $lda*m$ if `left_right = side::left`, or $lda*n$ if `left_right = side::right`. See *Matrix Storage* for more details.

lda Leading dimension of A. Must be at least m if `left_right = side::left`, and at least n if `left_right = side::right`. Must be positive.

b Buffer holding input/output matrix B. Must have size at least $ldb*n$ if column major layout is used to store matrices or at least $ldb*m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.

ldb Leading dimension of B. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

Output Parameters

b Output buffer. Overwritten by the solution matrix X.

Notes

If $\alpha = 0$, matrix B is set to zero, and A and B do not need to be initialized at entry.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

trsm (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event trsm(sycl::queue &queue,
                    onemkl::side left_right,
                    onemkl::uplo upper_lower,
                    onemkl::transpose transa,
                    onemkl::diag unit_diag,
                    std::int64_t m,
                    std::int64_t n,
                    T alpha,

Parent topic: *BLAS Routines*

BLAS-like Extensions

oneAPI Math Kernel Library DPC++ provides additional routines to extend the functionality of the BLAS routines. These include routines to compute many independent vector-vector and matrix-matrix operations.

The following table lists the BLAS-like extensions with their descriptions.

Routines	Description
<i>axpy_batch</i>	Computes groups of vector-scalar products added to a vector.
<i>gemm_batch</i>	Computes groups of matrix-matrix products with general matrices.
<i>trsm_batch</i>	Solves a triangular matrix equation for a group of matrices.
<i>gemmt</i>	Computes a matrix-matrix product with general matrices, but updates only the upper or lower triangular part of the result matrix.
<i>gemm_bias</i>	Computes a matrix-matrix product using general integer matrices with bias
<i>imatcopy</i>	Computes an in-place matrix transposition or copy.
<i>omatcopy</i>	Computes an out-of-place matrix transposition or copy.
<i>omatcopy2</i>	Computes a two-strided out-of-place matrix transposition or copy.
<i>omatadd</i>	Computes scaled matrix addition with possibly transposed arguments.
<i>imat-copy_batch</i>	Computes groups of in-place matrix transposition or copy operations.
<i>omat-copy_batch</i>	Computes groups of out-of-place matrix transposition or copy operations.
<i>omatadd_batch</i>	Computes groups of scaled matrix additions.

axpy_batch

Computes a group of axpy operations.

Description

The `axpy_batch` routines are batched versions of `axpy`, performing multiple axpy operations in a single call. Each axpy operation adds a scalar-vector product to a vector.

`axpy_batch` supports the following precisions for data.

T
float
double
std::complex<float>
std::complex<double>

axpy_batch (Buffer Version)

Description

The buffer version of `axpy_batch` supports only the strided API.

The strided API operation is defined as:

```

for i = 0 ... batch_size - 1
  X and Y are vectors at offset i * stridex, i * stridey in x and y
  Y := alpha * X + Y
end for

```

where:

alpha is scalar,

X and Y are vectors.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
  void axpy_batch(sycl::queue &queue,
                 std::int64_t n,
                 T alpha,
                 sycl::buffer<T,
                 1> &x,
                 std::int64_t incx,
                 std::int64_t stridex,
                 sycl::buffer<T,
                 1> &y,
                 std::int64_t incy,
                 std::int64_t stridey,

```

(continues on next page)

(continued from previous page)

```

        std::int64_t batch_size)
    }

```

```

namespace oneapi::mkl::blas::row_major {
    void axpy_batch(sycl::queue &queue,
                   std::int64_t n,
                   T alpha,
                   sycl::buffer<T,
                       1> &x,
                   std::int64_t incx,
                   std::int64_t stridex,
                   sycl::buffer<T,
                       1> &y,
                   std::int64_t incy,
                   std::int64_t stridey,
                   std::int64_t batch_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in X and Y.

alpha Specifies the scalar alpha.

x Buffer holding input vectors X with size `stridex * batch_size`.

incx Stride of vector X.

stridex Stride between different X vectors.

y Buffer holding input/output vectors Y with size `stridey * batch_size`.

incy Stride of vector Y.

stridey Stride between different Y vectors.

batch_size Specifies the number of axpy operations to perform.

Output Parameters

y Output buffer, overwritten by `batch_size` axpy operations of the form $\alpha * X + Y$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

axpy_batch (USM Version)

Description

The USM version of `axpy_batch` supports the group API and strided API.

The group API operation is defined as

```
idx = 0
for i = 0 ... group_count - 1
  for j = 0 ... group_size - 1
    X and Y are vectors in x[idx] and y[idx]
    Y := alpha[i] * X + Y
    idx := idx + 1
  end for
end for
```

The strided API operation is defined as

```
for i = 0 ... batch_size - 1
  X and Y are vectors at offset i * stridex, i * stridey in x and y
  Y := alpha * X + Y
end for
```

where:

`alpha` is scalar,

`X` and `Y` are vectors.

For group API, `x` and `y` arrays contain the pointers for all the input vectors. The total number of vectors in `x` and `y` are given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For strided API, `x` and `y` arrays contain all the input vectors. The total number of vectors in `x` and `y` are given by the `batch_size` parameter.

Group API

Syntax

```
namespace oneapi::mkl::blas::column_major {
  sycl::event axpy_batch(sycl::queue &queue,
                       const std::int64_t *n,
                       const T *alpha,
                       const T **x,
                       const std::int64_t *incx,
                       T **y,
                       const std::int64_t *incy,
                       std::int64_t group_count,
```

(continues on next page)

(continued from previous page)

```

        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
    }

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event axpy_batch(sycl::queue &queue,
        const std::int64_t *n,
        const T *alpha,
        const T **x,
        const std::int64_t *incx,
        T **y,
        const std::int64_t *incy,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Array of `group_count` integers. `n[i]` specifies the number of elements in vectors X and Y for every vector in group `i`.

alpha Array of `group_count` scalar elements. `alpha[i]` specifies the scaling factor for vector X in group `i`.

x Array of pointers to input vectors X with size `total_batch_count`. The size of array allocated for the X vector of the group `i` must be at least $(1 + (n[i] - 1) * \text{abs}(incx[i]))$. See *Matrix Storage* for more details.

incx Array of `group_count` integers. `incx[i]` specifies the stride of vector X in group `i`.

y Array of pointers to input/output vectors Y with size `total_batch_count`. The size of array allocated for the Y vector of the group `i` must be at least $(1 + (n[i] - 1) * \text{abs}(incy[i]))$. See *Matrix Storage* for more details.

incy Array of `group_count` integers. `incy[i]` specifies the stride of vector Y in group `i`.

group_count Number of groups. Must be at least 0.

group_size Array of `group_count` integers. `group_size[i]` specifies the number of axpy operations in group `i`. Each element in `group_size` must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Array of pointers holding the Y vectors, overwritten by `total_batch_count` axpy operations of the form $\text{alpha} * X + Y$.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event axpy_batch(sycl::queue &queue,
        std::int64_t n,
        T alpha,
        const T *x,
        std::int64_t incx,
        std::int64_t stridex,
        T *y,
        std::int64_t incy,
        std::int64_t stridey,
        std::int64_t batch_size,
        const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event axpy_batch(sycl::queue &queue,
        std::int64_t n,
        T alpha,
        const T *x,
        std::int64_t incx,
        std::int64_t stridex,
        T *y,
        std::int64_t incy,
        std::int64_t stridey,
        std::int64_t batch_size,
        const std::vector<sycl::event> &dependencies = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in X and Y.

alpha Specifies the scalar alpha.

x Pointer to input vectors X with size `stridex * batch_size`.

incx Stride of vector X.

stridex Stride between different X vectors.

y Pointer to input/output vectors Y with size `stridey * batch_size`.

incy Stride of vector Y.

stridey Stride between different Y vectors.

batch_size Specifies the number of `axpy` operations to perform.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

`y` Output vectors, overwritten by `batch_size` `axpy` operations of the form $\alpha * X + Y$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

axpby

Computes a vector-scalar product added to a scaled-vector.

Description

The `axpby` routines compute two scalar-vector product and add them:

$$y \leftarrow \beta * y + \alpha * x$$

where `x` and `y` are vectors of `n` elements and `alpha` and `beta` are scalars.

`axpby` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

axpby (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void axpby(sycl::queue &queue,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x, std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y, std::int64_t incy)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void axpby(sycl::queue &queue,
              std::int64_t n,
              T alpha,
              sycl::buffer<T,1> &x, std::int64_t incx,
              T beta,
              sycl::buffer<T,1> &y, std::int64_t incy)
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x** and **y**.

alpha Specifies the scalar **alpha**.

x Buffer holding input vector **x**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride between two consecutive elements of the **x** vector.

beta Specifies the scalar **beta**.

y Buffer holding input vector **y**. The buffer must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride between two consecutive elements of the **y** vector.

Output Parameters

y Buffer holding the updated vector **y**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

axpby (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event axpby(sycl::queue &queue,
                    std::int64_t n,
                    T alpha,
                    const T *x, std::int64_t incx,
                    const T beta,
                    T *y, std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event axpby(sycl::queue &queue,
                    std::int64_t n,
                    T alpha,
                    const T *x, std::int64_t incx,
                    const T beta,
                    T *y, std::int64_t incy,
                    const std::vector<sycl::event> &dependencies = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in vector **x** and **y**.

alpha Specifies the scalar alpha.

beta Specifies the scalar beta.

x Pointer to the input vector **x**. The allocated memory must be of size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. See *Matrix Storage* for more details.

incx Stride between consecutive elements of the **x** vector.

y Pointer to the input vector **y**. The allocated memory must be of size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. See *Matrix Storage* for more details.

incy Stride between consecutive elements of the *y* vector.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Array holding the updated vector *y*.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

copy_batch

Computes a group of copy operations.

Description

The `copy_batch` routines are batched versions of `copy`, performing multiple copy operations in a single call. Each copy operation copies one vector to another.

`copy_batch` supports the following precisions for data.

T
float
double
std::complex<float>
std::complex<double>

copy_batch (Buffer Version)

Description

The buffer version of `copy_batch` supports only the strided API.

The strided API operation is defined as:

```

for i = 0 ... batch_size - 1
  X and Y are vectors at offset i * stridex, i * stridey in x and y
  Y := X
end for

```

where:

X and Y are vectors.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
  void copy_batch(sycl::queue &queue,
                 std::int64_t n,
                 sycl::buffer<T,
                 1> &x,
                 std::int64_t incx,
                 std::int64_t stridex,
                 sycl::buffer<T,
                 1> &y,
                 std::int64_t incy,
                 std::int64_t stridey,
                 std::int64_t batch_size)
}

```

```

namespace oneapi::mkl::blas::row_major {
  void copy_batch(sycl::queue &queue,
                 std::int64_t n,
                 sycl::buffer<T,
                 1> &x,
                 std::int64_t incx,
                 std::int64_t stridex,
                 sycl::buffer<T,
                 1> &y,
                 std::int64_t incy,
                 std::int64_t stridey,
                 std::int64_t batch_size)
}

```

Input Parameters

- queue** The queue where the routine should be executed.
- n** Number of elements in X and Y.
- x** Buffer holding input vectors X with size `stridex * batch_size`.
- incx** Stride of vector X.
- stridex** Stride between different X vectors.
- y** Buffer holding input/output vectors Y with size `stridey * batch_size`.
- incy** Stride of vector Y.
- stridey** Stride between different Y vectors.
- batch_size** Specifies the number of copy operations to perform.

Output Parameters

- y** Output buffer, overwritten by `batch_size` copy operations.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

copy_batch (USM Version)

Description

The USM version of `copy_batch` supports the group API and strided API.

The group API operation is defined as

```

idx = 0
for i = 0 ... group_count - 1
  for j = 0 ... group_size - 1
    X and Y are vectors in x[idx] and y[idx]
    Y := X
    idx := idx + 1
  end for
end for

```

The strided API operation is defined as

```

for i = 0 ... batch_size - 1
  X and Y are vectors at offset i * stridex, i * stridey in x and y
  Y := X
end for

```

where:

X and Y are vectors.

For group API, x and y arrays contain the pointers for all the input vectors. The total number of vectors in x and y are given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For strided API, x and y arrays contain all the input vectors. The total number of vectors in x and y are given by the batch_size parameter.

Group API

Syntax

```

namespace oneapi::mkl::blas::column_major {
  sycl::event copy_batch(sycl::queue &queue,
                        const std::int64_t *n,
                        const T **x,
                        const std::int64_t *incx,
                        T **y,
                        const std::int64_t *incy,
                        std::int64_t group_count,
                        const std::int64_t *group_size,
                        const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
  sycl::event copy_batch(sycl::queue &queue,
                        const std::int64_t *n,
                        const T **x,
                        const std::int64_t *incx,
                        T **y,
                        const std::int64_t *incy,
                        std::int64_t group_count,
                        const std::int64_t *group_size,
                        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n Array of `group_count` integers. `n[i]` specifies the number of elements in vectors X and Y for every vector in group `i`.

x Array of pointers to input vectors X with size `total_batch_count`. The size of array allocated for the X vector of the group `i` must be at least $(1 + (n[i] - 1) * \text{abs}(\text{incx}[i]))$. See *Matrix Storage* for more details.

incx Array of `group_count` integers. `incx[i]` specifies the stride of vector X in group `i`.

y Array of pointers to input/output vectors Y with size `total_batch_count`. The size of array allocated for the Y vector of the group `i` must be at least $(1 + (n[i] - 1) * \text{abs}(\text{incy}[i]))$. See *Matrix Storage* for more details.

incy Array of `group_count` integers. `incy[i]` specifies the stride of vector Y in group `i`.

group_count Number of groups. Must be at least 0.

group_size Array of `group_count` integers. `group_size[i]` specifies the number of copy operations in group `i`. Each element in `group_size` must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Array of pointers holding the Y vectors, overwritten by `total_batch_count` copy operations.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event copy_batch(sycl::queue &queue,
                          std::int64_t n,
                          const T *x,
                          std::int64_t incx,
                          std::int64_t stridex,
                          T *y,
                          std::int64_t incy,
                          std::int64_t stridey,
                          std::int64_t batch_size,
                          const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event copy_batch(sycl::queue &queue,
                          std::int64_t n,
                          const T *x,
                          std::int64_t incx,
                          std::int64_t stridex,
```

(continues on next page)

(continued from previous page)

```

    T *y,
    std::int64_t incy,
    std::int64_t stridey,
    std::int64_t batch_size,
    const std::vector<sycl::event> &dependencies = {}
}

```

Input Parameters

queue The queue where the routine should be executed.

n Number of elements in X and Y.

x Pointer to input vectors X with size `stridex * batch_size`.

inex Stride of vector X.

stridex Stride between different X vectors.

y Pointer to input/output vectors Y with size `stridey * batch_size`.

incy Stride of vector Y.

stridey Stride between different Y vectors.

batch_size Specifies the number of copy operations to perform.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Output vectors, overwritten by `batch_size` copy operations

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Parent topic: *BLAS-like Extensions*

dgmm_batch

Computes a group of dgmm operations.

Description

The dgmm_batch routines perform multiple diagonal matrix-matrix product operations in a single call.

dgmm_batch supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

dgmm_batch (Buffer Version)

Description

The buffer version of dgmm_batch supports only the strided API.

The strided API operation is defined as:

```

for i = 0 ... batch_size - 1
  A and C are matrices at offset i * stridea in a, i * stridec in c.
  X is a vector at offset i * stridex in x
  C := diag(X) * A or C = A * diag(X)
end for

```

where:

A is a matrix,

X is a diagonal matrix stored as a vector

The a and x buffers contain all the input matrices. The stride between matrices is given by the stride parameter. The total number of matrices in a and x buffers is given by the batch_size parameter.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
  void dgmm_batch(sycl::queue &queue,
                 onemkl::mkl::side left_right,
                 std::int64_t m,
                 std::int64_t n,
                 sycl::buffer<T,1> &a,
                 std::int64_t lda,
                 std::int64_t stridea,
                 sycl::buffer<T,1> &x,
                 std::int64_t incx,

```

(continues on next page)

(continued from previous page)

```

        std::int64_t stridex,
        sycl::buffer<T,1> &c,
        std::int64_t ldc,
        std::int64_t stridec,
        std::int64_t batch_size)
    }

```

```

namespace oneapi::mkl::blas::row_major {
    void dgemm_batch(sycl::queue &queue,
                    onemkl::mkl::side left_right,
                    std::int64_t m,
                    std::int64_t n,
                    sycl::buffer<T,1> &a,
                    std::int64_t lda,
                    std::int64_t stridea,
                    sycl::buffer<T,1> &x,
                    std::int64_t incx,
                    std::int64_t stridex,
                    sycl::buffer<T,1> &c,
                    std::int64_t ldc,
                    std::int64_t stridec,
                    std::int64_t batch_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies the position of the diagonal matrix in the product. See *oneMKL defined datatypes* for more details.

m Number of rows of matrices A and C. Must be at least zero.

n Number of columns of matrices A and C. Must be at least zero.

a

Buffer holding the input matrices A with size $\text{stridea} * \text{batch_size}$. Must be of at least $\text{lda} * j + \text{stridea} * (\text{batch_size} - 1)$ where j is n if column major layout is used or m if major layout is used.

lda The leading dimension of the matrices A. It must be positive and at least m if column major layout is used or at least n if row major layout is used.

stridea Stride between different A matrices.

x Buffer holding the input matrices X with size $\text{stridex} * \text{batch_size}$. Must be of size at least $(1 + (\text{len} - 1) * \text{abs}(\text{incx})) + \text{stridex} * (\text{batch_size} - 1)$ where len is n if the diagonal matrix is on the right of the product or m otherwise.

incx Stride between two consecutive elements of the x vectors.

stridex Stride between different X vectors, must be at least 0.

c Buffer holding input/output matrices C with size $\text{stridec} * \text{batch_size}$.

ldc The leading dimension of the matrices C. It must be positive and at least m if column major layout is used to store matrices or at least n if column major layout is used to store matrices.

stridec Stride between different C matrices. Must be at least $ldc * n$ if column major layout is used or $ldc * m$ if row major layout is used.

batch_size Specifies the number of diagonal matrix-matrix product operations to perform.

Output Parameters

c Output overwritten by `batch_size` diagonal matrix-matrix product operations.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

dgmm_batch (USM Version)

Description

The USM version of `dgmm_batch` supports the group API and strided API.

The group API operation is defined as:

```

idx = 0
for i = 0 ... group_count - 1
  for j = 0 ... group_size - 1
    a and c are matrices of size mxn at position idx in a_array and c_array
    x is a vector of size m or n depending on left_right, at position idx in x_array
    if (left_right == oneapi::mkl::side::left)
      c := diag(x) * a
    else
      c := a * diag(x)
    idx := idx + 1
  end for
end for
end for

```

The strided API operation is defined as

```

for i = 0 ... batch_size - 1
  A and C are matrices at offset i * stridea in a, i * stridec in c.
  X is a vector at offset i * stridex in x
  C := diag(X) * A or C = A * diag(X)
end for

```

where:

A is a matrix,

X is a diagonal matrix stored as a vector

The `a` and `x` buffers contain all the input matrices. The stride between matrices is given by the `stride` parameter. The total number of matrices in `a` and `x` buffers is given by the `batch_size` parameter.

For group API, `a` and `x` arrays contain the pointers for all the input matrices. The total number of matrices in `a` and `x` are given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For strided API, `a` and `x` arrays contain all the input matrices. The total number of matrices in `a` and `x` are given by the `batch_size` parameter.

Group API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event dgemm_batch(sycl::queue &queue,
        const onemkl::mkl::side *left_right,
        const std::int64_t *m,
        const std::int64_t *n,
        const T **a,
        const std::int64_t *lda,
        const T **x,
        const std::int64_t *incx,
        T **c,
        const std::int64_t *ldc,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event dgemm_batch(sycl::queue &queue,
        const onemkl::mkl::side *left_right,
        const std::int64_t *m,
        const std::int64_t *n,
        const T **a,
        const std::int64_t *lda,
        const T **x,
        const std::int64_t *incx,
        T **c,
        const std::int64_t *ldc,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
}
```

Input Parameters

- queue** The queue where the routine should be executed.
- left_right** Specifies the position of the diagonal matrix in the product. See *oneMKL defined datatypes* for more details.
- m** Array of `group_count` integers. `m[i]` specifies the number of rows of A for every matrix in group `i`. All entries must be at least zero.
- n** Array of `group_count` integers. `n[i]` specifies the number of columns of A for every matrix in group `i`. All entries must be at least zero.
- a** Array of pointers to input matrices A with size `total_batch_count`. Must be of size at least `lda[i] * n[i]` if column major layout is used or at least `lda[i] * m[i]` if row major layout is used. See *Matrix Storage* for more details.
- lda** Array of `group_count` integers. `lda[i]` specifies the leading dimension of A for every matrix in group `i`. All entries must be positive and at least `m[i]` if column major layout is used or at least `n[i]` if row major layout is used.
- x** Array of pointers to input vectors X with size `total_batch_count`. Must be of size at least $(1 + \text{len}[i] - 1) * \text{abs}(\text{incx}[i])$ where `len[i]` is `n[i]` if the diagonal matrix is on the right of the product or `m[i]` otherwise. See *Matrix Storage* for more details.
- incx** Array of `group_count` integers. `incx[i]` specifies the stride of `x` for every vector in group `i`. All entries must be positive.
- c** Array of pointers to input/output matrices C with size `total_batch_count`. Must be of size at least `ldc[i] * n[i]` if column major layout is used or at least `ldc[i] * m[i]` if row major layout is used. See *Matrix Storage* for more details.
- ldc** Array of `group_count` integers. `ldc[i]` specifies the leading dimension of C for every matrix in group `i`. All entries must be positive and `ldc[i]` must be at least `m[i]` if column major layout is used to store matrices or at least `n[i]` if row major layout is used to store matrices.
- group_count** Specifies the number of groups. Must be at least 0.
- group_size** Array of `group_count` integers. `group_size[i]` specifies the number of diagonal matrix-matrix product operations in group `i`. All entries must be at least 0.
- dependencies** List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

- c** Output overwritten by `batch_size` diagonal matrix-matrix product operations.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event dgemm_batch(sycl::queue &queue,
                          onemkl::mkl::side left_right,
                          std::int64_t m,
                          std::int64_t n,
                          const T *a,
                          std::int64_t lda,
                          std::int64_t stridea,
                          const T *b,
                          std::int64_t incx,
                          std::int64_t stridex,
                          T *c,
                          std::int64_t ldc,
                          std::int64_t stridec,
                          std::int64_t batch_size,
                          const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {

}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies the position of the diagonal matrix in the product. See *oneMKL defined datatypes* for more details.

m Number of rows of A. Must be at least zero.

n Number of columns of A. Must be at least zero.

a Pointer to input matrices A with size $\text{stridea} * \text{batch_size}$. Must be of size at least $\text{lda} * k + \text{stridea} * (\text{batch_size} - 1)$ where k is n if column major layout is used or m if row major layout is used.

lda The leading dimension of the matrices A. It must be positive and at least m . Must be positive and at least m if column major layout is used or at least n if row major layout is used.

stridea Stride between different A matrices.

x Pointer to input matrices X with size `stridex * batch_size`. Must be of size at least $(1 + (\text{len} - 1) * \text{abs}(\text{incx})) + \text{stridex} * (\text{batch_size} - 1)$ where `len` is `n` if the diagonal matrix is on the right of the product or `m` otherwise.

incx Stride between two consecutive elements of the `x` vector.

stridex Stride between different X vectors, must be at least 0.

c Pointer to input/output matrices C with size `stridex * batch_size`.

ldc The leading dimension of the matrices C. It must be positive and at least `ldc * m` if column major layout is used to store matrices or at least `ldc * n` if row major layout is used to store matrices.

stridex Stride between different C matrices. Must be at least `ldc * n` if column major layout is used or `ldc * m` if row major layout is used.

batch_size Specifies the number of diagonal matrix-matrix product operations to perform.

Output Parameters

c Output overwritten by `batch_size` diagonal matrix-matrix product operations.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

gemm_batch

Computes a group of `gemm` operations.

Description

The `gemm_batch` routines are batched versions of `gemm`, performing multiple `gemm` operations in a single call. Each `gemm` operation perform a matrix-matrix product with general matrices.

`gemm_batch` supports the following precisions.

Ta (A matrix)	Tb (B matrix)	Tc (C matrix)	Ts (alpha/beta)
std::int8_t	std::int8_t	std::int32_t	float
std::int8_t	std::int8_t	float	float
half	half	float	float
half	half	half	half
bfloat16	bfloat16	float	float
bfloat16	bfloat16	bfloat16	float
float	float	float	float
double	double	double	double
std::complex<float>	std::complex<float>	std::complex<float>	std::complex<float>
std::complex<double>	std::complex<double>	std::complex<double>	std::complex<double>

gemm_batch (Buffer Version)

Description

The buffer version of `gemm_batch` supports only the strided API.

The strided API operation is defined as:

```

for i = 0 ... batch_size - 1
  A, B and C are matrices at offset i * stridea, i * strideb, i * stridec in a, b and c.
  C := alpha * op(A) * op(B) + beta * C
end for

```

where:

$op(X)$ is one of $op(X) = X$, or $op(X) = X^T$, or $op(X) = X^H$,

alpha and beta are scalars,

A, B, and C are matrices,

$op(A)$ is $m \times k$, $op(B)$ is $k \times n$, and C is $m \times n$.

The a, b and c buffers contain all the input matrices. The stride between matrices is given by the stride parameter. The total number of matrices in a, b and c buffers is given by the `batch_size` parameter.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void gemm_batch(sycl::queue &queue,
                   onemkl::transpose transa,
                   onemkl::transpose transb,
                   std::int64_t m,
                   std::int64_t n,
                   std::int64_t k,
                   T alpha,
                   sycl::buffer<T,1> &a,
                   std::int64_t lda,
                   std::int64_t stridea,
                   sycl::buffer<T,1> &b,
                   std::int64_t ldb,
                   std::int64_t strideb,
                   T beta,
                   sycl::buffer<T,1> &c,
                   std::int64_t ldc,
                   std::int64_t stridec,
                   std::int64_t batch_size)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void gemm_batch(sycl::queue &queue,
                   onemkl::transpose transa,
                   onemkl::transpose transb,
                   std::int64_t m,
                   std::int64_t n,
                   std::int64_t k,
                   T alpha,
                   sycl::buffer<T,1> &a,
                   std::int64_t lda,
                   std::int64_t stridea,
                   sycl::buffer<T,1> &b,
                   std::int64_t ldb,
                   std::int64_t strideb,
                   T beta,
                   sycl::buffer<T,1> &c,
                   std::int64_t ldc,
                   std::int64_t stridec,
                   std::int64_t batch_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies $\text{op}(A)$ the transposition operation applied to the matrices A. See *oneMKL defined datatypes* for more details.

transb Specifies $\text{op}(B)$ the transposition operation applied to the matrices B. See *oneMKL defined datatypes* for more details.

m Number of rows of $\text{op}(A)$ and C. Must be at least zero.

n Number of columns of $\text{op}(B)$ and C. Must be at least zero.

k Number of columns of $\text{op}(A)$ and rows of $\text{op}(B)$. Must be at least zero.

alpha Scaling factor for the matrix-matrix products.

a Buffer holding the input matrices A with size `stridea * batch_size`.

lda The leading dimension of the matrices A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least m.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least m.

stridea Stride between different A matrices.

b Buffer holding the input matrices B with size `strideb * batch_size`.

ldb The leading dimension of the matrices ``B``. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least k.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least k.

strideb Stride between different B matrices.

beta Scaling factor for the matrices C.

c Buffer holding input/output matrices C with size `stridec * batch_size`.

ldc The leading dimension of the matrices C. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

stridec Stride between different C matrices. Must be at least `ldc * n`.

batch_size Specifies the number of matrix multiply operations to perform.

Output Parameters

c Output buffer, overwritten by `batch_size` matrix multiply operations of the form $\text{alpha} * \text{op}(A) * \text{op}(B) + \text{beta} * C$.

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `gemm_batch`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

gemm_batch (USM Version)

Description

The USM version of `gemm_batch` supports the group API and the strided API. The group API supports pointer and span inputs.

The group API operation is defined as:

```
idx = 0
for i = 0 ... group_count - 1
  for j = 0 ... group_size - 1
    A, B, and C are matrices in a[idx], b[idx] and c[idx]
    C := alpha[i] * op(A) * op(B) + beta[i] * C
    idx = idx + 1
  end for
end for
```

The advantage of using span instead of pointer is that the sizes of the array can vary and the size of the span can be queried at runtime. For each GEMM parameter, except the output matrices, the span can be of size 1, the number of groups or the total batch size. For the output matrices, to ensure all computation are independent, the size of the span must be the total batch size.

Depending on the size of the spans, each parameter for the GEMM computation is used as follows:

- If the span has size 1, the parameter is reused for all GEMM computation.
- If the span has size `group_count`, the parameter is reused for all GEMM within a group, but each group will have a different value for this parameter. This is like the `gemm_batch` group API with pointers.
- If the span has size equal to the total batch size, each GEMM computation will use a different value for this parameter.

The strided API operation is defined as

```
for i = 0 ... batch_size - 1
  A, B and C are matrices at offset i * stridea, i * strideb, i * stridec in a, b and
  ↪ c.
```

(continues on next page)

(continued from previous page)

```
C := alpha * op(A) * op(B) + beta * C
end for
```

where:

op(X) is one of op(X) = X, or op(X) = X^T, or op(X) = X^H,

alpha and beta are scalars,

A, B, and C are matrices,

op(A) is m x k, op(B) is k x n, and C is m x n.

For group API, a, b and c arrays contain the pointers for all the input matrices. The total number of matrices in a, b and c are given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For strided API, a, b, c arrays contain all the input matrices. The total number of matrices in a, b and c are given by the batch_size parameter.

Group API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event gemm_batch(sycl::queue &queue,
                          const onemkl::transpose *transa,

}

```

Input Parameters

queue The queue where the routine should be executed.

transa Array or span of `group_count` `onemkl::transpose` values. `transa[i]` specifies the form of `op(A)` used in the matrix multiplication in group `i`. See *oneMKL defined datatypes* for more details.

transb Array or span of `group_count` `onemkl::transpose` values. `transb[i]` specifies the form of `op(B)` used in the matrix multiplication in group `i`. See *oneMKL defined datatypes* for more details.

m Array or span of `group_count` integers. `m[i]` specifies the number of rows of `op(A)` and `C` for every matrix in group `i`. All entries must be at least zero.

n Array or span of `group_count` integers. `n[i]` specifies the number of columns of `op(B)` and `C` for every matrix in group `i`. All entries must be at least zero.

k Array or span of `group_count` integers. `k[i]` specifies the number of columns of `op(A)` and rows of `op(B)` for every matrix in group `i`. All entries must be at least zero.

alpha Array or span of `group_count` scalar elements. `alpha[i]` specifies the scaling factor for every matrix-matrix product in group `i`.

a Array of pointers or span of input matrices `A` with size `total_batch_count`.

See *Matrix Storage* for more details.

lda Array or span of `group_count` integers. `lda[i]` specifies the leading dimension of `A` for every matrix in group `i`. All entries must be positive.

	A not transposed	A transposed
Column major	<code>lda[i]</code> must be at least <code>m[i]</code> .	<code>lda[i]</code> must be at least <code>k[i]</code> .
Row major	<code>lda[i]</code> must be at least <code>k[i]</code> .	<code>lda[i]</code> must be at least <code>m[i]</code> .

b Array of pointers or span of input matrices `B` with size `total_batch_count`.

See *Matrix Storage* for more details.

ldb Array or span of `group_count` integers. `ldb[i]` specifies the leading dimension of `B` for every matrix in group `i`. All entries must be positive.

	B not transposed	B transposed
Column major	<code>ldb[i]</code> must be at least <code>k[i]</code> .	<code>ldb[i]</code> must be at least <code>n[i]</code> .
Row major	<code>ldb[i]</code> must be at least <code>n[i]</code> .	<code>ldb[i]</code> must be at least <code>k[i]</code> .

beta Array or span of `group_count` scalar elements. `beta[i]` specifies the scaling factor for matrix `C` for every matrix in group `i`.

c Array of pointers or span of input/output matrices `C` with size `total_batch_count`.

See *Matrix Storage* for more details.

ldc Array or span of `group_count` integers. `ldc[i]` specifies the leading dimension of `C` for every matrix in group `i`. All entries must be positive and `ldc[i]` must be at least `m[i]` if column major layout is used to store matrices or at least `n[i]` if row major layout is used to store matrices.

group_count Specifies the number of groups. Must be at least 0.

group_size Array or span of `group_count` integers. `group_size[i]` specifies the number of matrix multiply products in group `i`. All entries must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Overwritten by the $m[i]$ -by- $n[i]$ matrix calculated by $(\alpha[i] * \text{op}(A) * \text{op}(B) + \beta[i] * C)$ for group i .

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `gemm_batch`.

Return Values

Output event to wait on to ensure computation is complete.

Output Parameters

c Overwritten by the $m[i]$ -by- $n[i]$ matrix calculated by $(\alpha[i] * \text{op}(A) * \text{op}(B) + \beta[i] * C)$ for group i .

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `gemm_batch`.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event gemm_batch(sycl::queue &queue,
                        onemkl::transpose transa,
                        onemkl::transpose transb,
                        std::int64_t m,
                        std::int64_t n,
                        std::int64_t k,
                        T alpha,
                        const T *a,

                        std::int64_t batch_size,
                        const std::vector<sycl::event> &dependencies = {})
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event gemm_batch(sycl::queue &queue,
                          onemkl::transpose transa,
                          onemkl::transpose transb,
                          std::int64_t m,
                          std::int64_t n,
                          std::int64_t k,
                          T alpha,
                          const T *a,
                          std::int64_t lda,
                          std::int64_t stridea,
                          const T *b,
                          std::int64_t ldb,
                          std::int64_t strideb,
                          T beta,
                          T *c,
                          std::int64_t ldc,
                          std::int64_t stridec,
                          std::int64_t batch_size,
                          const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies op(A) the transposition operation applied to the matrices A. See *oneMKL defined datatypes* for more details.

transb Specifies op(B) the transposition operation applied to the matrices B. See *oneMKL defined datatypes* for more details.

m Number of rows of op(A) and C. Must be at least zero.

n Number of columns of op(B) and C. Must be at least zero.

k Number of columns of op(A) and rows of op(B). Must be at least zero.

alpha Scaling factor for the matrix-matrix products.

a Pointer to input matrices A with size `stridea * batch_size`.

lda The leading dimension of the matrices A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least m.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least m.

stridea Stride between different A matrices.

b Pointer to input matrices B with size `strideb * batch_size`.

ldb The leading dimension of the matrices ``B``. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least k.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least k.

strideb Stride between different B matrices.

beta Scaling factor for the matrices C.

c Pointer to input/output matrices C with size `stridec * batch_size`.

ldc The leading dimension of the matrices C. It must be positive and at least `m` if column major layout is used to store matrices or at least `n` if row major layout is used to store matrices.

stridec Stride between different C matrices.

batch_size Specifies the number of matrix multiply operations to perform.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Output matrices, overwritten by `batch_size` matrix multiply operations of the form $\alpha * \text{op}(A) * \text{op}(B) + \beta * C$.

Notes

If `beta = 0`, matrix C does not need to be initialized before calling `gemm_batch`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

gemv_batch

Computes a group of `gemv` operations.

Description

The `gemv_batch` routines are batched versions of `gemv`, performing multiple `gemv` operations in a single call. Each `gemv` operations perform a scalar-matrix-vector product and add the result to a scalar-vector product.

`gemv_batch` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

`gemv_batch` (Buffer Version)

Description

The buffer version of `gemv_batch` supports only the strided API.

The strided API operation is defined as:

```
for i = 0 ... batch_size - 1
  A is a matrix at offset i * stridea in a.
  X and Y are matrices at offset i * stridex, i * stridey, in x and y.
  Y := alpha * op(A) * X + beta * Y
end for
```

where:

$op(A)$ is one of $op(A) = A$, or $op(A) = A^T$, or $op(A) = A^H$,

α and β are scalars,

A is a matrix and X and Y are vectors,

The x and y buffers contain all the input matrices. The stride between vectors is given by the `stride` parameter. The total number of vectors in x and y buffers is given by the `batch_size` parameter.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
  void gemv_batch(sycl::queue &queue,
                 onemkl::transpose trans,
                 std::int64_t m,
                 std::int64_t n,
                 T alpha,
                 sycl::buffer<T,1> &a,
                 std::int64_t lda,
                 std::int64_t stridea,
                 sycl::buffer<T,1> &x,
                 std::int64_t incx,
                 std::int64_t stridex,
```

(continues on next page)

(continued from previous page)

```

        T beta,
        sycl::buffer<T,1> &y,
        std::int64_t incy,
        std::int64_t stridey,
        std::int64_t batch_size)
    }

```

```

namespace oneapi::mkl::blas::row_major {
    void gemv_batch(sycl::queue &queue,
                   onemkl::transpose trans,
                   std::int64_t m,
                   std::int64_t n,
                   T alpha,
                   sycl::buffer<T,1> &a,
                   std::int64_t lda,
                   std::int64_t stridea,
                   sycl::buffer<T,1> &x,
                   std::int64_t incx,
                   std::int64_t stridex,
                   T beta,
                   sycl::buffer<T,1> &y,
                   std::int64_t incy,
                   std::int64_t stridey,
                   std::int64_t batch_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $\text{op}(A)$ the transposition operation applied to the matrices A . See *oneMKL defined datatypes* for more details.

m Number of rows of $\text{op}(A)$. Must be at least zero.

n Number of columns of $\text{op}(A)$. Must be at least zero.

alpha Scaling factor for the matrix-vector products.

a Buffer holding the input matrices A with size $\text{stridea} * \text{batch_size}$.

lda The leading dimension of the matrices A . It must be positive and at least m if column major layout is used or at least n if row major layout is used.

stridea Stride between different A matrices.

x Buffer holding the input vectors X with size $\text{stridex} * \text{batch_size}$.

incx The stride of the vector X . It must be positive.

stridex Stride between different consecutive X vectors, must be at least 0.

beta Scaling factor for the vector Y .

y Buffer holding input/output vectors Y with size $\text{stridey} * \text{batch_size}$.

incy Stride between two consecutive elements of the y vectors.

stridex Stride between two consecutive Y vectors. Must be at least $(1 + (\text{len}-1)*\text{abs}(\text{incy}))$ where len is m if the matrix A is non transpose or n otherwise.

batch_size Specifies the number of matrix-vector operations to perform.

Output Parameters

y Output overwritten by batch_size matrix-vector product operations of the form $\text{alpha} * \text{op}(A) * X + \text{beta} * Y$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

gemv_batch (USM Version)

Description

The USM version of gemv_batch supports the group API and strided API.

The group API operation is defined as:

```
idx = 0
for i = 0 ... group_count - 1
  for j = 0 ... group_size - 1
    A is an m x n matrix in a[idx]
    X and Y are vectors in x[idx] and y[idx]
    Y := alpha[i] * op(A) * X + beta[i] * Y
    idx = idx + 1
  end for
end for
```

The strided API operation is defined as

```
for i = 0 ... batch_size - 1
  A is a matrix at offset i * stridea in a.
  X and Y are vectors at offset i * stridex, i * stridey in x and y.
  Y := alpha * op(A) * X + beta * Y
end for
```

where:

op(A) is one of $\text{op}(A) = A$, or $\text{op}(A) = A^T$, or $\text{op}(A) = A^H$,

alpha and beta are scalars,

A is a matrix and X and Y are vectors,

For group API, *x* and *y* arrays contain the pointers for all the input vectors. *A* array contains the pointers to all input matrices. The total number of vectors in *x* and *y* and matrices in *A* are given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For strided API, *x* and *y* arrays contain all the input vectors. *A* array contains the pointers to all input matrices. The total number of vectors in *x* and *y* and matrices in *A* are given by the *batch_size* parameter.

Group API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event gemv_batch(sycl::queue &queue,
        const onemkl::transpose *trans,
        const std::int64_t *m,
        const std::int64_t *n,
        const T *alpha,
        const T **a,
        const std::int64_t *lda,
        const T **x,
        const std::int64_t *incx,
        const T *beta,
        T **y,
        const std::int64_t *incy,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
}

```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event gemv_batch(sycl::queue &queue,
        const onemkl::transpose *trans,
        const std::int64_t *m,
        const std::int64_t *n,
        const T *alpha,
        const T **a,
        const std::int64_t *lda,
        const T **x,
        const std::int64_t *incx,
        const T *beta,
        T **y,
        const std::int64_t *incy,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Array of `group_count` `onemkl::transpose` values. `trans[i]` specifies the form of `op(A)` used in the matrix-vector product in group `i`. See *oneMKL defined datatypes* for more details.

m Array of `group_count` integers. `m[i]` specifies the number of rows of `op(A)` for every matrix in group `i`. All entries must be at least zero.

n Array of `group_count` integers. `n[i]` specifies the number of columns of `op(A)` for every matrix in group `i`. All entries must be at least zero.

alpha Array of `group_count` scalar elements. `alpha[i]` specifies the scaling factor for every matrix-vector product in group `i`.

a Array of pointers to input matrices `A` with size `total_batch_count`.

See *Matrix Storage* for more details.

lda Array of `group_count` integers. `lda[i]` specifies the leading dimension of `A` for every matrix in group `i`. All entries must be positive and at least `m` if column major layout is used or at least `n` if row major layout is used.

x Array of pointers to input vectors `X` with size `total_batch_count`.

See *Matrix Storage* for more details.

incx Array of `group_count` integers. `incx[i]` specifies the stride of `X` for every vector in group `i`. All entries must be positive.

beta Array of `group_count` scalar elements. `beta[i]` specifies the scaling factor for vector `Y` for every vector in group `i`.

y Array of pointers to input/output vectors `Y` with size `total_batch_count`.

See *Matrix Storage* for more details.

incy Array of `group_count` integers. `incy[i]` specifies the leading dimension of `Y` for every vector in group `i`. All entries must be positive and `incy[i]` must be at least `m[i]` if column major layout is used or at least `n[i]` if row major layout is used.

group_count Specifies the number of groups. Must be at least 0.

group_size Array of `group_count` integers. `group_size[i]` specifies the number of matrix-vector products in group `i`. All entries must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

y Overwritten by vector calculated by $(\text{alpha}[i] * \text{op}(A) * X + \text{beta}[i] * Y)$ for group `i`.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event gemv_batch(sycl::queue &queue,
        onemkl::transpose trans,
        std::int64_t m,
        std::int64_t n,
        T alpha,
        const T *a,
        std::int64_t lda,
        std::int64_t stridea,
        const T *x,
        std::int64_t incx,
        std::int64_t stridex,
        T beta,
        T *y,
        std::int64_t incy,
        std::int64_t stridey,
        std::int64_t batch_size,
        const std::vector<sycl::event> &dependencies = {})
}

```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event gemv_batch(sycl::queue &queue,
        onemkl::transpose trans,
        std::int64_t m,
        std::int64_t n,
        T alpha,
        const T *a,
        std::int64_t lda,
        std::int64_t stridea,
        const T *x,
        std::int64_t incx,
        std::int64_t stridex,
        T beta,
        T *y,
        std::int64_t incy,
        std::int64_t stridey,
        std::int64_t batch_size,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $\text{op}(A)$ the transposition operation applied to the matrices A . See *oneMKL defined datatypes* for more details.

m Number of rows of $\text{op}(A)$. Must be at least zero.

n Number of columns of $\text{op}(A)$. Must be at least zero.

alpha Scaling factor for the matrix-vector products.

a Pointer to the input matrices A with size $\text{stridea} * \text{batch_size}$.

lda The leading dimension of the matrices A . It must be positive and at least m if column major layout is used or at least n if row major layout is used.

stridea Stride between different A matrices.

x Pointer to the input vectors X with size $\text{stridex} * \text{batch_size}$.

incx Stride of the vector X . It must be positive.

stridex Stride between different consecutive X vectors, must be at least 0.

beta Scaling factor for the vector Y .

y Pointer to the input/output vectors Y with size $\text{stridey} * \text{batch_size}$.

incy Stride between two consecutive elements of the y vectors.

stridey Stride between two consecutive Y vectors. Must be at least $(1 + (\text{len}-1)*\text{abs}(\text{incy}))$ where len is m if the matrix A is non transpose or n otherwise.

batch_size Specifies the number of matrix-vector operations to perform.

Output Parameters

y Output overwritten by batch_size matrix-vector product operations of the form $\text{alpha} * \text{op}(A) * X + \text{beta} * Y$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

syrk_batch

Computes a group of `syrk` operations.

Description

The `syrk_batch` routines are batched versions of `syrk`, performing multiple `syrk` operations in a single call. Each `syrk` operation perform a rank-k update with general matrices.

`syrk_batch` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

syrk_batch (Buffer Version)

Description

The buffer version of `syrk_batch` supports only the strided API.

The strided API operation is defined as:

```

for i = 0 ... batch_size - 1
  A and C are matrices at offset i * stridea, i * stridec in a and c.
  C := alpha * op(A) * op(A)^T + beta * C
end for

```

where:

$op(X)$ is one of $op(X) = X$, or $op(X) = X^T$, or $op(X) = X^H$,

α and β are scalars,

A and C are matrices,

$op(A)$ is $n \times k$ and C is $n \times n$.

The `a` and `c` buffers contain all the input matrices. The stride between matrices is given by the `stride` parameter. The total number of matrices in `a` and `c` buffers is given by the `batch_size` parameter.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
  void syrk_batch(sycl::queue &queue,
                 onemkl::uplo upper_lower,
                 onemkl::transpose trans,
                 std::int64_t n,
                 std::int64_t k,
                 T alpha,

```

(continues on next page)

(continued from previous page)

```

sycl::buffer<T,1> &a,
std::int64_t lda,
std::int64_t stridea,
T beta,
sycl::buffer<T,1> &c,
std::int64_t ldc,
std::int64_t stridec,
std::int64_t batch_size)
}

```

```

namespace oneapi::mkl::blas::row_major {
void syrk_batch(sycl::queue &queue,
onemkl::uplo upper_lower,
onemkl::transpose trans,
std::int64_t n,
std::int64_t k,
T alpha,
sycl::buffer<T,1> &a,
std::int64_t lda,
std::int64_t stridea,
T beta,
sycl::buffer<T,1> &c,
std::int64_t ldc,
std::int64_t stridec,
std::int64_t batch_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether data in C is stored in its upper or lower triangle. For more details, see *oneMKL defined datatypes*.

trans Specifies op(A) the transposition operation applied to the matrix A. Conjugation is never performed, even if trans = transpose::conjtrans. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of C. Must be at least zero.

k Number of columns of op(A). Must be at least zero.

alpha Scaling factor for the rank-k update.

a Buffer holding the input matrices A with size stridea * batch_size.

lda The leading dimension of the matrices A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least n.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least n.

stridea Stride between different A matrices.

beta Scaling factor for the matrices C.

c Buffer holding input/output matrices C with size `stridedc * batch_size`.

ldc The leading dimension of the matrices C. It must be positive and at least `n`.

stridedc Stride between different C matrices. Must be at least `ldc * n`.

batch_size Specifies the number of rank-k update operations to perform.

Output Parameters

c Output buffer, overwritten by `batch_size` rank-k update operations of the form $\alpha * \text{op}(A) * \text{op}(A)^T + \beta * C$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

syrk_batch (USM Version)

Description

The USM version of `syrk_batch` supports the group API and strided API.

The group API operation is defined as:

```
idx = 0
for i = 0 ... group_count - 1
  for j = 0 ... group_size - 1
    A, B, and C are matrices in a[idx] and c[idx]
    C := alpha[i] * op(A) * op(A)^T + beta[i] * C
    idx = idx + 1
  end for
end for
```

The strided API operation is defined as

```
for i = 0 ... batch_size - 1
  A, B and C are matrices at offset i * stridea, i * stridedc in a and c.
  C := alpha * op(A) * op(A)^T + beta * C
end for
```

where:

$\text{op}(X)$ is one of $\text{op}(X) = X$, or $\text{op}(X) = X^T$, or $\text{op}(X) = X^H$,

α and β are scalars,

A and C are matrices,

$op(A)$ is $n \times k$ and C is $n \times n$.

For group API, a and c arrays contain the pointers for all the input matrices. The total number of matrices in a and c are given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For strided API, a and c arrays contain all the input matrices. The total number of matrices in a and c are given by the `batch_size` parameter.

Group API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event syr_k_batch(sycl::queue &queue,
        const uplo *upper_lower,
        const transpose *trans,
        const std::int64_t *n,
        const std::int64_t *k,
        const T *alpha,
        const T **a,
        const std::int64_t *lda,
        const T *beta,
        T **c,
        const std::int64_t *ldc,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event syr_k_batch(sycl::queue &queue,
        const uplo *upper_lower,
        const transpose *trans,
        const std::int64_t *n,
        const std::int64_t *k,
        const T *alpha,
        const T **a,
        const std::int64_t *lda,
        const T *beta,
        T **c,
        const std::int64_t *ldc,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Array of `group_count` `onemkl::upper_lower` values. `upper_lower[i]` specifies whether data in C for every matrix in group `i` is in upper or lower triangle.

trans Array of `group_count` `onemkl::transpose` values. `trans[i]` specifies the form of `op(A)` used in the rank-`k` update in group `i`. See *oneMKL defined datatypes* for more details.

n Array of `group_count` integers. `n[i]` specifies the number of rows and columns of C for every matrix in group `i`. All entries must be at least zero.

k Array of `group_count` integers. `k[i]` specifies the number of columns of `op(A)` for every matrix in group `i`. All entries must be at least zero.

alpha Array of `group_count` scalar elements. `alpha[i]` specifies the scaling factor for every rank-`k` update in group `i`.

a Array of pointers to input matrices A with size `total_batch_count`.
See *Matrix Storage* for more details.

lda Array of `group_count` integers. `lda[i]` specifies the leading dimension of A for every matrix in group `i`. All entries must be positive.

	A not transposed	A transposed
Column major	<code>lda[i]</code> must be at least <code>n[i]</code> .	<code>lda[i]</code> must be at least <code>k[i]</code> .
Row major	<code>lda[i]</code> must be at least <code>k[i]</code> .	<code>lda[i]</code> must be at least <code>n[i]</code> .

beta Array of `group_count` scalar elements. `beta[i]` specifies the scaling factor for matrix C for every matrix in group `i`.

c Array of pointers to input/output matrices C with size `total_batch_count`.
See *Matrix Storage* for more details.

ldc Array of `group_count` integers. `ldc[i]` specifies the leading dimension of C for every matrix in group `i`. All entries must be positive and `ldc[i]` must be at least `n[i]`.

group_count Specifies the number of groups. Must be at least 0.

group_size Array of `group_count` integers. `group_size[i]` specifies the number of rank-`k` update products in group `i`. All entries must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Overwritten by the `n[i]`-by-`n[i]` matrix calculated by $(\text{alpha}[i] * \text{op}(A) * \text{op}(A)^T + \text{beta}[i] * C)$ for group `i`.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event syr_k_batch(sycl::queue &queue,
        uplo upper_lower,
        transpose trans,
        std::int64_t n,
        std::int64_t k,
        T alpha,
        const T *a,
        std::int64_t lda,
        std::int64_t stride_a,
        T beta,
        T *c,
        std::int64_t ldc,
        std::int64_t stride_c,
        std::int64_t batch_size,
        const std::vector<sycl::event> &dependencies = {})
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event syr_k_batch(sycl::queue &queue,
        uplo upper_lower,
        transpose trans,
        std::int64_t n,
        std::int64_t k,
        T alpha,
        const T *a,
        std::int64_t lda,
        std::int64_t stride_a,
        T beta,
        T *c,
        std::int64_t ldc,
        std::int64_t stride_c,
        std::int64_t batch_size,
        const std::vector<sycl::event> &dependencies = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether data in C is stored in its upper or lower triangle. For more details, see *oneMKL defined datatypes*.

trans Specifies $\text{op}(A)$ the transposition operation applied to the matrices A. Conjugation is never performed, even if $\text{trans} = \text{transpose}::\text{conjtrans}$. See *oneMKL defined datatypes* for more details.

n Number of rows and columns of C. Must be at least zero.

k Number of columns of $\text{op}(A)$. Must be at least zero.

alpha Scaling factor for the rank-k updates.

a Pointer to input matrices A with size $\text{stridea} * \text{batch_size}$.

lda The leading dimension of the matrices A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least n.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least n.

stridea Stride between different A matrices.

beta Scaling factor for the matrices C.

c Pointer to input/output matrices C with size $\text{stridec} * \text{batch_size}$.

ldc The leading dimension of the matrices C. It must be positive and at least n.

stridec Stride between different C matrices.

batch_size Specifies the number of rank-k update operations to perform.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Output matrices, overwritten by batch_size rank-k update operations of the form $\text{alpha} * \text{op}(A) * \text{op}(A)^T + \text{beta} * C$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

trsm_batch

Computes a group of `trsm` operations.

Description

The `trsm_batch` routines are batched versions of `trsm`, performing multiple `trsm` operations in a single call. Each `trsm` solves an equation of the form $\text{op}(A) * X = \alpha * B$ or $X * \text{op}(A) = \alpha * B$.

`trsm_batch` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

trsm_batch (Buffer Version)

Description

The buffer version of `trsm_batch` supports only the strided API.

The strided API operation is defined as:

```

for i = 0 ... batch_size - 1
  A and B are matrices at offset i * stridea and i * strideb in a and b.
  if (left_right == onemkl::side::left) then
    compute X such that op(A) * X = alpha * B
  else
    compute X such that X * op(A) = alpha * B
  end if
  B := X
end for

```

where:

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A^T$, or $\text{op}(A) = A^H$,

α is a scalar,

A is a triangular matrix,

B and X are $m \times n$ general matrices,

A is either $m \times m$ or $n \times n$, depending on whether it multiplies X on the left or right. On return, the matrix B is overwritten by the solution matrix X .

The a and b buffers contain all the input matrices. The stride between matrices is given by the `stride` parameter. The total number of matrices in a and b buffers are given by the `batch_size` parameter.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void trsm_batch(sycl::queue &queue,
                   onemkl::side left_right,
                   onemkl::uplo upper_lower,
                   onemkl::transpose trans,
                   onemkl::diag unit_diag,
                   std::int64_t m,
                   std::int64_t n,
                   T alpha,
                   sycl::buffer<T,1> &a,
                   std::int64_t lda,
                   std::int64_t stridea,
                   sycl::buffer<T,1> &b,
                   std::int64_t ldb,
                   std::int64_t strideb,
                   std::int64_t batch_size)
}
```

```
namespace oneapi::mkl::blas::row_major {
    void trsm_batch(sycl::queue &queue,
                   onemkl::side left_right,
                   onemkl::uplo upper_lower,
                   onemkl::transpose trans,
                   onemkl::diag unit_diag,
                   std::int64_t m,
                   std::int64_t n,
                   T alpha,
                   sycl::buffer<T,1> &a,
                   std::int64_t lda,
                   std::int64_t stridea,
                   sycl::buffer<T,1> &b,
                   std::int64_t ldb,
                   std::int64_t strideb,
                   std::int64_t batch_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether the matrices A multiply X on the left (`side::left`) or on the right (`side::right`). See *oneMKL defined datatypes* for more details.

upper_lower Specifies whether the matrices A are upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to the matrices A. See *oneMKL defined datatypes* for more details.

unit_diag Specifies whether the matrices A are assumed to be unit triangular (all diagonal elements are 1). See *oneMKL defined datatypes* for more details.

m Number of rows of the B matrices. Must be at least zero.

n Number of columns of the B matrices. Must be at least zero.

alpha Scaling factor for the solutions.

a Buffer holding the input matrices A with size `stridea * batch_size`.

lda Leading dimension of the matrices A. Must be at least `m` if `left_right = side::left`, and at least `n` if `left_right = side::right`. Must be positive.

stridea Stride between different A matrices.

b Buffer holding the input matrices B with size `strideb * batch_size`.

ldb Leading dimension of the matrices B. It must be positive and at least `m` if column major layout is used to store matrices or at least `n` if row major layout is used to store matrices.

strideb Stride between different B matrices.

batch_size Specifies the number of triangular linear systems to solve.

Output Parameters

b Output buffer, overwritten by `batch_size` solution matrices X.

Notes

If `alpha = 0`, matrix B is set to zero and the matrices A and B do not need to be initialized before calling `trsm_batch`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

trsm_batch (USM Version)

Description

The USM version of `trsm_batch` supports the group API and strided API.

The group API operation is defined as:

```

idx = 0
for i = 0 ... group_count - 1
  for j = 0 ... group_size - 1
    A and B are matrices in a[idx] and b[idx]
    if (left_right == onemkl::side::left) then
      compute X such that op(A) * X = alpha[i] * B

```

(continues on next page)

(continued from previous page)

```

else
    compute X such that X * op(A) = alpha[i] * B
end if
B := X
idx = idx + 1
end for
end for

```

The strided API operation is defined as:

```

for i = 0 ... batch_size - 1
    A and B are matrices at offset i * stridea and i * strideb in a and b.
    if (left_right == onemkl::side::left) then
        compute X such that op(A) * X = alpha * B
    else
        compute X such that X * op(A) = alpha * B
    end if
    B := X
end for

where:

```

op(A) is one of op(A) = A, or op(A) = A^T, or op(A) = A^H,

alpha is a scalar,

A is a triangular matrix,

B and X are m x n general matrices,

A is either m x m or n x n, depending on whether it multiplies X on the left or right. On return, the matrix B is overwritten by the solution matrix X.

For group API, a and b arrays contain the pointers for all the input matrices. The total number of matrices in a and b are given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For strided API, a and b arrays contain all the input matrices. The total number of matrices in a and b are given by the batch_size parameter.

Group API

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event trsm_batch(sycl::queue &queue,
                          const onemkl::side *left_right,
                          const onemkl::uplo *upper_lower,
                          const onemkl::transpose *trans,
                          const onemkl::diag *unit_diag,
                          const std::int64_t *m,
                          const std::int64_t *n,

```

(continues on next page)

(continued from previous page)

```

        const T *alpha,
        const T **a,
        const std::int64_t *lda,
        T **b,
        const std::int64_t *ldb,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
    }

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event trsm_batch(sycl::queue &queue,
        const onemkl::side *left_right,
        const onemkl::uplo *upper_lower,
        const onemkl::transpose *trans,
        const onemkl::diag *unit_diag,
        const std::int64_t *m,
        const std::int64_t *n,
        const T *alpha,
        const T **a,
        const std::int64_t *lda,
        T **b,
        const std::int64_t *ldb,
        std::int64_t group_count,
        const std::int64_t *group_size,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Array of `group_count` `onemkl::side` values. `left_right[i]` specifies whether A multiplies X on the left (`side::left`) or on the right (`side::right`) for every `trsm` operation in group `i`. See *oneMKL defined datatypes* for more details.

upper_lower Array of `group_count` `onemkl::uplo` values. `upper_lower[i]` specifies whether A is upper or lower triangular for every matrix in group `i`. See *oneMKL defined datatypes* for more details.

trans Array of `group_count` `onemkl::transpose` values. `trans[i]` specifies the form of `op(A)` used for every `trsm` operation in group `i`. See *oneMKL defined datatypes* for more details.

unit_diag Array of `group_count` `onemkl::diag` values. `unit_diag[i]` specifies whether A is assumed to be unit triangular (all diagonal elements are 1) for every matrix in group `i`. See *oneMKL defined datatypes* for more details.

m Array of `group_count` integers. `m[i]` specifies the number of rows of B for every matrix in group `i`. All entries must be at least zero.

n Array of `group_count` integers. `n[i]` specifies the number of columns of B for every matrix in group `i`. All entries must be at least zero.

alpha Array of `group_count` scalar elements. `alpha[i]` specifies the scaling factor in group `i`.

a Array of pointers to input matrices A with size `total_batch_count`. See *Matrix Storage* for more details.

lda Array of `group_count` integers. `lda[i]` specifies the leading dimension of A for every matrix in group `i`. All entries must be at least `m` if `left_right` is `side::left`, and at least `n` if `left_right` is `side::right`. All entries must be positive.

b Array of pointers to input matrices B with size `total_batch_count`. See *Matrix Storage* for more details.

ldb Array of `group_count` integers. `ldb[i]` specifies the leading dimension of B for every matrix in group `i`. All entries must be positive and at least `m` and positive if column major layout is used to store matrices or at least `n` if row major layout is used to store matrices.

group_count Specifies the number of groups. Must be at least 0.

group_size Array of `group_count` integers. `group_size[i]` specifies the number of `trsm` operations in group `i`. All entries must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

b Output buffer, overwritten by the `total_batch_count` solution matrices X.

Notes

If `alpha = 0`, matrix B is set to zero and the matrices A and B do not need to be initialized before calling `trsm_batch`.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event trsm_batch(sycl::queue &queue,
                        onemkl::side left_right,
                        onemkl::uplo upper_lower,
                        onemkl::transpose trans,
                        onemkl::diag unit_diag,
                        std::int64_t m,
                        std::int64_t n,
                        T alpha,
                        const T *a,
                        std::int64_t lda,
                        std::int64_t stridea,
                        T *b,
                        std::int64_t ldb,
                        std::int64_t strideb,
                        std::int64_t batch_size,
                        const std::vector<sycl::event> &dependencies = {})
}
```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event trsm_batch(sycl::queue &queue,
                          onemkl::side left_right,
                          onemkl::uplo upper_lower,
                          onemkl::transpose trans,
                          onemkl::diag unit_diag,
                          std::int64_t m,
                          std::int64_t n,
                          T alpha,
                          const T *a,
                          std::int64_t lda,
                          std::int64_t stridea,
                          T *b,
                          std::int64_t ldb,
                          std::int64_t strideb,
                          std::int64_t batch_size,
                          const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

left_right Specifies whether the matrices A multiply X on the left (`side::left`) or on the right (`side::right`). See *oneMKL defined datatypes* for more details.

upper_lower Specifies whether the matrices A are upper or lower triangular. See *oneMKL defined datatypes* for more details.

trans Specifies $op(A)$, the transposition operation applied to the matrices A. See *oneMKL defined datatypes* for more details.

unit_diag Specifies whether the matrices A are assumed to be unit triangular (all diagonal elements are 1). See *oneMKL defined datatypes* for more details.

m Number of rows of the B matrices. Must be at least zero.

n Number of columns of the B matrices. Must be at least zero.

alpha Scaling factor for the solutions.

a Pointer to input matrices A with size `stridea * batch_size`.

lda Leading dimension of the matrices A. Must be at least m if `left_right = side::left`, and at least n if `left_right = side::right`. Must be positive.

stridea Stride between different A matrices.

b Pointer to input matrices B with size `strideb * batch_size`.

ldb Leading dimension of the matrices B. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.

strideb Stride between different B matrices.

batch_size Specifies the number of triangular linear systems to solve.

Output Parameters

b Output matrices, overwritten by `batch_size` solution matrices **X**.

Notes

If `alpha = 0`, matrix **B** is set to zero and the matrices **A** and **B** do not need to be initialized before calling `trsm_batch`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

gemmt

Computes a matrix-matrix product with general matrices, but updates only the upper or lower triangular part of the result matrix.

Description

The `gemmt` routines compute a scalar-matrix-matrix product and add the result to the upper or lower part of a scalar-matrix product, with general matrices. The operation is defined as:

$$C \leftarrow \alpha * op(A) * op(B) + \beta * C$$

where:

`op(X)` is one of `op(X) = X`, or `op(X) = XT`, or `op(X) = XH`,

`alpha` and `beta` are scalars

A, **B**, and **C** are matrices

`op(A)` is `n x k`, `op(B)` is `k x n`, and **C** is `n x n`.

`gemmt` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

gemmt (Buffer Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void gemmt(sycl::queue &queue,
               onemkl::uplo upper_lower,
               onemkl::transpose transa,
               onemkl::transpose transb,
               std::int64_t n,
               std::int64_t k,
               T alpha,
               sycl::buffer<T,1> &a,
               std::int64_t lda,
               sycl::buffer<T,1> &b,

               std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether C's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

transa Specifies $\text{op}(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

transb Specifies $\text{op}(B)$, the transposition operation applied to B. See *oneMKL defined datatypes* for more details.

n Number of rows of $\text{op}(A)$, columns of $\text{op}(B)$, and columns and rows of C. Must be at least zero.

k Number of columns of $\text{op}(A)$ and rows of $\text{op}(B)$. Must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Buffer holding the input matrix A.

	A not transposed	A transposed
Column major	A is an n-by-k matrix so the array a must have size at least $\text{lda} * k$.	A is a k-by-n matrix so the array a must have size at least $\text{lda} * n$
Row major	A is an n-by-k matrix so the array a must have size at least $\text{lda} * n$.	A is an k-by-n matrix so the array a must have size at least $\text{lda} * k$.

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least n.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least n.

b Buffer holding the input matrix B.

	B not transposed	B transposed
Column major	B is an k-by-n matrix so the array b must have size at least $\text{ldb} * n$.	B is an n-by-k matrix so the array b must have size at least $\text{ldb} * k$
Row major	B is an k-by-n matrix so the array b must have size at least $\text{ldb} * k$.	B is an n-by-k matrix so the array b must have size at least $\text{ldb} * n$.

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least k.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least k.

beta Scaling factor for matrix C.

c Buffer holding the input/output matrix C. Must have size at least $\text{ldc} * n$. See *Matrix Storage* for more details.

ldc Leading dimension of C. Must be positive and at least m.

Output Parameters

c Output buffer, overwritten by the upper or lower triangular part of $\alpha * \text{op}(A) * \text{op}(B) + \beta * C$.

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `gemmt`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

gemmt (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event gemmt(sycl::queue &queue,
                    onemkl::uplo upper_lower,
                    onemkl::transpose transa,
                    onemkl::transpose transb,
                    std::int64_t n,
                    std::int64_t k,

Input Parameters

queue The queue where the routine should be executed.

upper_lower Specifies whether C's data is stored in its upper or lower triangle. See *oneMKL defined datatypes* for more details.

transa Specifies op(A), the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

transb Specifies op(B), the transposition operation applied to B. See *oneMKL defined datatypes* for more details.

n Number of columns of op(A), columns of op(B), and columns of C. Must be at least zero.

k Number of columns of op(A) and rows of op(B). Must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Pointer to input matrix A.

	A not transposed	A transposed
Column major	A is an n-by-k matrix so the array a must have size at least lda*k.	A is an k-by-n matrix so the array a must have size at least lda*n
Row major	A is an n-by-k matrix so the array a must have size at least lda*n.	A is an k-by-n matrix so the array a must have size at least lda*k

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least n.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least n.

b Pointer to input matrix B.

	B not transposed	B transposed
Column major	B is an k-by-n matrix so the array b must have size at least ldb*n.	B is an n-by-k matrix so the array b must have size at least ldb*k
Row major	B is an k-by-n matrix so the array b must have size at least ldb*k.	B is an n-by-k matrix so the array b must have size at least ldb*n

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least k.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least k.

beta Scaling factor for matrix C.

c Pointer to input/output matrix C. Must have size at least ldc * n. See *Matrix Storage* for more details.

ldc Leading dimension of C. Must be positive and at least m.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Pointer to the output matrix, overwritten by the upper or lower triangular part of $\alpha * \text{op}(A) * \text{op}(B) + \text{beta} * C$.

Notes

If $\text{beta} = 0$, matrix C does not need to be initialized before calling gemmt.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

gemm_bias

Computes a matrix-matrix product using general integer matrices with bias.

Description

The `gemm_bias` routines compute a scalar-matrix-matrix product and add the result to a scalar-matrix product, using general integer matrices with biases/offsets. The operation is defined as:

$$C \leftarrow \alpha * (\text{op}(A) - A_offset) * (\text{op}(B) - B_offset) + \beta * C + C_offset$$

where:

`op(X)` is one of `op(X) = X`, or `op(X) = XT`, or `op(X) = XH`,

`alpha` and `beta` are scalars,

`A_offset` is an `m`-by-`k` matrix with every element equal to the value `ao`,

`B_offset` is a `k`-by-`n` matrix with every element equal to the value `bo`,

`C_offset` is an `m`-by-`n` matrix defined by the `co` buffer as described below,

`A`, `B`, and `C` are matrices,

`op(A)` is `m` x `k`, `op(B)` is `k` x `n`, and `C` is `m` x `n`.

`gemm_bias` supports the following precisions.

Ta	Tb
<code>std::uint8_t</code>	<code>std::uint8_t</code>
<code>std::int8_t</code>	<code>std::uint8_t</code>
<code>std::uint8_t</code>	<code>std::int8_t</code>
<code>std::int8_t</code>	<code>std::int8_t</code>

`gemm_bias` (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void gemm_bias(sycl::queue &queue,
                  onemkl::transpose transa,
                  onemkl::transpose transb,
                  onemkl::offset offset_type,
                  std::int64_t m,
                  std::int64_t n,
                  std::int64_t k,
                  float alpha,
                  sycl::buffer<Ta,1> &a,
                  std::int64_t lda,
                  Ta ao,
                  sycl::buffer<Tb,1> &b,
                  std::int64_t ldb,
                  Tb bo,
                  float beta,
                  sycl::buffer<std::int32_t,1> &c,
                  std::int64_t ldc,
                  sycl::buffer<std::int32_t,1> &co)
}

```

```

namespace oneapi::mkl::blas::row_major {
    void gemm_bias(sycl::queue &queue,
                  onemkl::transpose transa,
                  onemkl::transpose transb,
                  onemkl::offset offset_type,
                  std::int64_t m,
                  std::int64_t n,
                  std::int64_t k,
                  float alpha,
                  sycl::buffer<Ta,1> &a,
                  std::int64_t lda,
                  Ta ao,
                  sycl::buffer<Tb,1> &b,
                  std::int64_t ldb,
                  Tb bo,
                  float beta,
                  sycl::buffer<std::int32_t,1> &c,
                  std::int64_t ldc,
                  sycl::buffer<std::int32_t,1> &co)
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies op(A), the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

transb Specifies op(B), the transposition operation applied to B. See *oneMKL defined datatypes* for more details.

offset_type Specifies the form of C_offset used in the matrix multiplication. See *oneMKL defined datatypes* for more details.

m Number of rows of op(A) and C. Must be at least zero.

n Number of columns of op(B) and C. Must be at least zero.

k Number of columns of op(A) and rows of op(B). Must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a The buffer holding the input matrix A.

	A not transposed	A transposed
Column major	A is an m-by-k matrix so the array a must have size at least lda*k.	A is an k-by-m matrix so the array a must have size at least lda*m
Row major	A is an m-by-k matrix so the array a must have size at least lda*m.	A is an k-by-m matrix so the array a must have size at least lda*k

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least m.	lda must be at least k.
Row major	lda must be at least k.	lda must be at least m.

- a0** Specifies the scalar offset value for matrix A.
- b** Buffer holding the input matrix B.

	B not transposed	B transposed
Column major	B is an k-by-n matrix so the array b must have size at least $ldb*n$.	B is an n-by-k matrix so the array b must have size at least $ldb*k$
Row major	B is an k-by-n matrix so the array b must have size at least $ldb*k$.	B is an n-by-k matrix so the array b must have size at least $ldb*n$

See *Matrix Storage* for more details.

- ldb** The leading dimension of B. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least k.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least k.

- bo** Specifies the scalar offset value for matrix B.
- beta** Scaling factor for matrix C.
- c** Buffer holding the input/output matrix C. It must have a size of at least $ldc*n$ if column major layout is used to store matrices or at least $ldc*m$ if row major layout is used to store matrices . See *Matrix Storage* for more details.
- ldc** The leading dimension of C. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.
- co** Buffer holding the offset values for matrix C.
 - If `offset_type = offset::fix`, the co array must have size at least 1.
 - If `offset_type = offset::col`, the co array must have size at least $\max(1,m)$.
 - If `offset_type = offset::row`, the co array must have size at least $\max(1,n)$.

Output Parameters

- c** Output buffer, overwritten by $\alpha * (\text{op}(A) - A_offset) * (\text{op}(B) - B_offset) + \beta * C + C_offset$.

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `gemv_bias`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

        Tb bo,
        float beta,
        std::int32_t *c,
        std::int64_t ldc,
        const std::int32_t *co,
        const std::vector<sycl::event> &dependencies = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies $\text{op}(A)$, the transposition operation applied to A. See *oneMKL defined datatypes* for more details.

transb Specifies $\text{op}(B)$, the transposition operation applied to B. See *oneMKL defined datatypes* for more details.

offset_type Specifies the form of `C_offset` used in the matrix multiplication. See *oneMKL defined datatypes* for more details.

m Number of rows of $\text{op}(A)$ and C. Must be at least zero.

n Number of columns of $\text{op}(B)$ and C. Must be at least zero.

k Number of columns of $\text{op}(A)$ and rows of $\text{op}(B)$. Must be at least zero.

alpha Scaling factor for the matrix-matrix product.

a Pointer to input matrix A.

	A not transposed	A transposed
Column major	A is an m -by- k matrix so the array a must have size at least $lda*k$.	A is an k -by- m matrix so the array a must have size at least $lda*m$
Row major	A is an m -by- k matrix so the array a must have size at least $lda*m$.	A is an k -by- m matrix so the array a must have size at least $lda*k$

See *Matrix Storage* for more details.

lda The leading dimension of A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least m .	lda must be at least k .
Row major	lda must be at least k .	lda must be at least m .

ao Specifies the scalar offset value for matrix A.

b Pointer to input matrix B.

	B not transposed	B transposed
Column major	B is an k -by- n matrix so the array b must have size at least $ldb*n$.	B is an n -by- k matrix so the array b must have size at least $ldb*k$
Row major	B is an k -by- n matrix so the array b must have size at least $ldb*k$.	B is an n -by- k matrix so the array b must have size at least $ldb*n$

See *Matrix Storage* for more details.

ldb The leading dimension of B. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least k .	ldb must be at least n .
Row major	ldb must be at least n .	ldb must be at least k .

bo Specifies the scalar offset value for matrix B.

beta Scaling factor for matrix C.

- c** Pointer to input/output matrix C. It must have a size of at least $ldc*n$ if column major layout is used to store matrices or at least $ldc*m$ if row major layout is used to store matrices. See *Matrix Storage* for more details.
- ldc** The leading dimension of C. It must be positive and at least m if column major layout is used to store matrices or at least n if row major layout is used to store matrices.
- co** Pointer to offset values for matrix C.
- If `offset_type = offset::fix`, the `co` array must have size at least 1.
- If `offset_type = offset::col`, the `co` array must have size at least $\max(1, m)$.
- If `offset_type = offset::row`, the `co` array must have size at least $\max(1, n)$.
- dependencies** List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

- c** Pointer to the output matrix, overwritten by $\alpha * (\text{op}(A) - A_offset) * (\text{op}(B) - B_offset) + \beta * C + C_offset$.

Notes

If $\beta = 0$, matrix C does not need to be initialized before calling `gemv_bias`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Parent topic: *BLAS-like Extensions*

imatcopy

Computes an in-place scaled matrix transpose or copy operation using a general dense matrix.

Description

The `imatcopy` routine performs an in-place scaled matrix copy or transposition.

The operation is defined as:

$$C \leftarrow \alpha * op(C)$$

where:

`op(X)` is one of `op(X) = X`, or `op(X) = XT`, or `op(X) = XH`,

`alpha` is a scalar,

`C` is a matrix to be transformed in place,

and `C` is `m x n` on input.

`imatcopy` supports the following precisions:

T
float
double
std::complex<float>
std::complex<double>

imatcopy (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void imatcopy(sycl::queue &queue,
                 oneapi::mkl::transpose trans,
                 std::int64_t m,
                 std::int64_t n,
                 T alpha,
                 sycl::buffer<T, 1> &matrix_in_out,
                 std::int64_t ld_in,
                 std::int64_t ld_out);
}
```

```
namespace oneapi::mkl::blas::row_major {
    void imatcopy(sycl::queue &queue,
                 oneapi::mkl::transpose trans,
                 std::int64_t m,
                 std::int64_t n,
                 T alpha,
                 sycl::buffer<T, 1> &matrix_in_out,
                 std::int64_t ld_in,
                 std::int64_t ld_out);
}
```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(C)$, the transposition operation applied to the matrix C . See *oneMKL defined datatypes* for more details.

m Number of rows of C on input. Must be at least zero.

n Number of columns of C on input. Must be at least zero.

alpha Scaling factor for the matrix transposition or copy.

matrix_in_out Buffer holding the input/output matrix C . Must have size as follows:

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>trans = transpose::conjtrans</code>
Column major	Size of array <code>matrix_in_out</code> must be at least $\max(\text{ld_in}, \text{ld_out}) * n$	Size of array <code>matrix_in_out</code> must be at least $\max(\text{ld_in}^{**}n, \text{ld_out}^{**}m)$
Row major	Size of array <code>matrix_in_out</code> must be at least $\max(\text{ld_in}, \text{ld_out}) * m$	Size of array <code>matrix_in_out</code> must be at least $\max(\text{ld_in}^{**}m, \text{ld_out}^{**}n)$

ld_in The leading dimension of the matrix C on input. It must be positive, and must be at least m if column major layout is used, and at least n if row-major layout is used.

ld_out The leading dimension of the matrix C on output. It must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>trans = transpose::conjtrans</code>
Column major	<code>ld_out</code> must be at least m .	<code>ld_out</code> must be at least n .
Row major	<code>ld_out</code> must be at least n .	<code>ld_out</code> must be at least m .

Output Parameters

matrix_in_out Output buffer, overwritten by $\alpha * op(C)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

imatcopy (USM Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event imatcopy(sycl::queue &queue,
        oneapi::mkl::transpose trans,
        std::int64_t m,
        std::int64_t n,
        T alpha,
        T *matrix_in_out,
        std::int64_t ld_in,
        std::int64_t ld_out,
        const std::vector<sycl::event> &dependencies = {});
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event imatcopy(sycl::queue &queue,
        oneapi::mkl::transpose trans,
        std::int64_t m,
        std::int64_t n,
        T alpha,
        T *matrix_in_out,
        std::int64_t ld_in,
        std::int64_t ld_out,
        const std::vector<sycl::event> &dependencies = {});
}
```

Input Parameters

queue The queue where the routine will be executed.

trans Specifies op(C), the transposition operation applied to the matrix C. See *oneMKL defined datatypes* for more details.

m Number of rows for the matrix C on input. Must be at least zero.

n Number of columns for the matrix C on input. Must be at least zero.

alpha Scaling factor for the matrix transpose or copy operation.

matrix_in_out

Pointer to input/output matrix C. Must have size as follows:

	trans = transpose::nontrans	trans = transpose::trans Or trans = transpose::conjtrans
Column major	Size of array matrix_in_out must be at least $\max(\text{ld_in}, \text{ld_out}) * n$	Size of array matrix_in_out must be at least $\max(\text{ld_in} * n, \text{ld_out} * m)$
Row major	Size of array matrix_in_out must be at least $\max(\text{ld_in}, \text{ld_out}) * m$	Size of array matrix_in_out must be at least $\max(\text{ld_in} * m, \text{ld_out} * n)$

ld_in Leading dimension of the matrix C on input. If matrices are stored using column major layout, ld_in must be at least m. If matrices are stored using row major layout, ld_in must be at least n. Must be positive.

ld_out Leading dimension of the matrix C on output. Must be positive.

	<code>trans</code> <code>transpose::nontrans</code>	=	<code>trans = transpose::trans</code> Or <code>trans = transpose::conjtrans</code>
Column major	<code>ld_out</code> must be at least <code>m</code> .		<code>ld_out</code> must be at least <code>n</code> .
Row major	<code>ld_out</code> must be at least <code>n</code> .		<code>ld_out</code> must be at least <code>m</code> .

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

matrix_in_out Pointer to output matrix C overwritten by $\alpha * op(C)$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

omatcopy

Computes an out-of-place scaled matrix transpose or copy operation using a general dense matrix.

Description

The `omatcopy` routine performs an out-of-place scaled matrix copy or transposition.

The operation is defined as:

$$B \leftarrow \alpha * op(A)$$

where:

`op(X)` is one of `op(X) = X`, or `op(X) = XT`, or `op(X) = XH`,

`alpha` is a scalar,

A and B are matrices,

A is m x n matrix,

B is $m \times n$ matrix if `op` is non-transpose and an $n \times m$ matrix otherwise.,
`omatcopy` supports the following precisions:

T
float
double
std::complex<float>
std::complex<double>

omatcopy (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void omatcopy(sycl::queue &queue,
                 oneapi::mkl::transpose trans,
                 std::int64_t m,
                 std::int64_t n,
                 T alpha,
                 sycl::buffer<T, 1> &a,
                 std::int64_t lda,
                 sycl::buffer<T, 1> &b,
                 std::int64_t ldb);
}
```

```
namespace oneapi::mkl::blas::row_major {
    void omatcopy(sycl::queue &queue,
                 oneapi::mkl::transpose trans,
                 std::int64_t m,
                 std::int64_t n,
                 T alpha,
                 sycl::buffer<T, 1> &a,
                 std::int64_t lda,
                 sycl::buffer<T, 1> &b,
                 std::int64_t ldb);
}
```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(A)$, the transposition operation applied to the matrix A. See *oneMKL defined datatypes* for more details.

m Number of rows for the matrix A. Must be at least zero.

n Number of columns for the matrix A. Must be at least zero.

alpha Scaling factor for the matrix transposition or copy.

a Buffer holding the input matrix A. Must have size at least $lda * n$ for column-major and at least $lda * m$ for row-major.

lda Leading dimension of the matrix A. If matrices are stored using column major layout, lda must be at least m. If matrices are stored using row major layout, lda must be at least n. Must be positive.

b Buffer holding the output matrix B.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>trans = transpose::conjtrans</code>
Column major	B is m x n matrix. Size of array b must be at least <code>ldb * n</code>	B is n x m matrix. Size of array b must be at least <code>ldb * m</code>
Row major	B is m x n matrix. Size of array b must be at least <code>ldb * m</code>	B is n x m matrix. Size of array b must be at least <code>ldb * n</code>

ldb The leading dimension of the matrix B. Must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>trans = transpose::conjtrans</code>
Column major	ldb must be at least m.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least m.

Output Parameters

b Output buffer, overwritten by $\alpha * \text{op}(A)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

        T *b,
        std::int64_t ldb,
        const std::vector<sycl::event> &dependencies = {});
}

```

Input Parameters

queue The queue where the routine will be executed.

trans Specifies $op(A)$, the transposition operation applied to the matrix A. See *oneMKL defined datatypes* for more details.

m Number of rows for the matrix A. Must be at least zero.

n Number of columns for the matrix A. Must be at least zero.

alpha Scaling factor for the matrix transposition or copy.

a Pointer to input matrix A. Must have size at least $lda * n$ for column-major and at least $lda * m$ for row-major.

lda Leading dimension of the matrix A. If matrices are stored using column major layout, lda must be at least m . If matrices are stored using row major layout, lda must be at least n . Must be positive.

b Pointer to output matrix B.

	trans = transpose::nontrans	trans = transpose::trans or trans = transpose::conjtrans
Column major	B is $m \times n$ matrix. Size of array b must be at least $ldb * n$	B is $n \times m$ matrix. Size of array b must be at least $ldb * m$
Row major	B is $m \times n$ matrix. Size of array b must be at least $ldb * m$	B is $n \times m$ matrix. Size of array b must be at least $ldb * n$

ldb Leading dimension of the matrix B. Must be positive.

	trans = transpose::nontrans	trans = transpose::trans or trans = transpose::conjtrans
Column major	Must be at least m	Must be at least n
Row major	Must be at least n	Must be at least m

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

b Pointer to output matrix B overwritten by $\alpha * op(A)$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

omatcopy2

Computes two-strided scaling and out-of-place transposition or copying of general dense matrices.

Description

The `omatcopy2` routine performs a two-strided scaling and out-of-place transposition or copy of matrices. For complex matrices the transpose operation can be a conjugate transpose.

Normally, matrices in the BLAS or LAPACK are specified by a single stride index. For instance, in the column-major order, $A(2, 1)$ is stored in memory one element away from $A(1, 1)$, but $A(1, 2)$ is a leading dimension away. The leading dimension in this case is at least the number of rows of the source matrix. If a matrix has two strides, then both $A(2, 1)$ and $A(1, 2)$ may be an arbitrary distance from $A(1, 1)$.

The operation is defined as:

$$B \leftarrow \alpha * op(A)$$

where:

$op(X)$ is one of $op(X) = X$, or $op(X) = X^T$, or $op(X) = X^H$,

α is a scalar,

A and B are matrices,

A is $m \times n$ matrix,

B is $m \times n$ matrix if op is non-transpose and an $n \times m$ matrix otherwise.,

`omatcopy2` supports the following precisions:

T
float
double
std::complex<float>
std::complex<double>

omatcopy2 (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void omatcopy2(sycl::queue &queue,
                  oneapi::mkl::transpose trans,
                  std::int64_t m,
                  std::int64_t n,
                  T alpha,
                  sycl::buffer<T, 1> &a,
                  std::int64_t lda,
                  std::int64_t stridea,
                  sycl::buffer<T, 1> &b,
                  std::int64_t ldb,
                  std::int64_t strideb);
}
```

```
namespace oneapi::mkl::blas::row_major {
    void omatcopy2(sycl::queue &queue,
                  oneapi::mkl::transpose trans,
                  std::int64_t m,
                  std::int64_t n,
                  T alpha,
                  sycl::buffer<T, 1> &a,
                  std::int64_t lda,
                  std::int64_t stridea,
                  sycl::buffer<T, 1> &b,
                  std::int64_t ldb,
                  std::int64_t strideb);
}
```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(A)$, the transposition operation applied to the matrix A . See *oneMKL defined datatypes* for more details.

m Number of rows for the matrix A . Must be at least zero.

n Number of columns for the matrix A . Must be at least zero.

alpha Scaling factor for the matrix transposition or copy.

a Buffer holding the input matrix A . Must have size at least $lda * n$ for column major ordering and at least $lda * m$ for row major ordering.

lda Leading dimension of the matrix A. If matrices are stored using column major layout, `lda` is the number of elements in the array between adjacent columns of the matrix, and must be at least $\text{stridea} * (m-1) + 1$. If using row major layout, `lda` is the number of elements between adjacent rows of the matrix and must be at least $\text{stridea} * (n-1) + 1$.

stridea The second stride of the matrix A. For column major layout, `stridea` is the number of elements in the array between adjacent rows of the matrix. For row major layout `stridea` is the number of elements between adjacent columns of the matrix. In both cases `stridea` must be at least 1.

b Buffer holding the output matrix B.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>trans = transpose::conjtrans</code>
Column major	B is $m \times n$ matrix. Size of buffer <code>b</code> must be at least $\text{ldb} * n$	B is $n \times m$ matrix. Size of buffer <code>b</code> must be at least $\text{ldb} * m$
Row major	B is $m \times n$ matrix. Size of buffer <code>b</code> must be at least $\text{ldb} * m$	B is $n \times m$ matrix. Size of buffer <code>b</code> must be at least $\text{ldb} * n$

ldb The leading dimension of the matrix B. Must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>trans = transpose::conjtrans</code>
Column major	<code>ldb</code> must be at least $\text{strideb} * (m-1) + 1$.	<code>ldb</code> must be at least $\text{strideb} * (n-1) + 1$.
Row major	<code>ldb</code> must be at least $\text{strideb} * (n-1) + 1$.	<code>ldb</code> must be at least $\text{strideb} * (m-1) + 1$.

strideb The second stride of the matrix B. For column major layout, `strideb` is the number of elements in the array between adjacent rows of the matrix. For row major layout, `strideb` is the number of elements between adjacent columns of the matrix. In both cases `strideb` must be at least 1.

Output Parameters

b Output buffer, overwritten by $\alpha * \text{op}(A)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

omatcopy2 (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event omatcopy2(sycl::queue &queue,
        oneapi::mkl::transpose trans,
        std::int64_t m,
        std::int64_t n,
        T alpha,
        const T *a,
        std::int64_t lda,
        std::int64_t stridea,
        T *b,
        std::int64_t ldb,
        std::int64_t strideb,
        const std::vector<sycl::event> &dependencies = {});
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event omatcopy2(sycl::queue &queue,
        oneapi::mkl::transpose trans,
        std::int64_t m,
        std::int64_t n,
        T alpha,
        const T *a,
        std::int64_t lda,
        std::int64_t stridea,
        T *b,
        std::int64_t ldb,
        std::int64_t strideb,
        const std::vector<sycl::event> &dependencies = {});
}

```

Input Parameters

queue The queue where the routine will be executed.

trans Specifies $op(A)$, the transposition operation applied to matrix A. See *oneMKL defined datatypes* for more details.

m Number of rows for the matrix A. Must be at least zero.

n Number of columns for the matrix A. Must be at least zero.

alpha Scaling factor for the matrix transposition or copy.

a Pointer to input matrix A. Must have size at least $lda * n$ for column-major and at least $lda * m$ for row-major.

lda Leading dimension of the matrix A. If matrices are stored using column major layout, lda is the number of elements in the array between adjacent columns of the matrix, and must be at least $stridea * (m-1) + 1$. If using row major layout, lda is the number of elements between adjacent rows of the matrix and must be at least $stridea * (n-1) + 1$.

stridea The second stride of the matrix A. For column major layout, $stridea$ is the number of elements in the array between adjacent rows of the matrix. For row major layout $stridea$ is the number of elements between adjacent

columns of the matrix. In both cases `stridea` must be at least 1.

b Pointer to output matrix B.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>trans = transpose::conjtrans</code>
Column major	B is $m \times n$ matrix. Size of array <code>b</code> must be at least <code>ldb * n</code>	B is $n \times m$ matrix. Size of array <code>b</code> must be at least <code>ldb * m</code>
Row major	B is $m \times n$ matrix. Size of array <code>b</code> must be at least <code>ldb * m</code>	B is $n \times m$ matrix. Size of array <code>b</code> must be at least <code>ldb * n</code>

ldb The leading dimension of the matrix B. Must be positive.

	<code>trans = transpose::nontrans</code>	<code>trans = transpose::trans</code> or <code>trans = transpose::conjtrans</code>
Column major	<code>ldb</code> must be at least <code>strideb * (m-1) + 1</code> .	<code>ldb</code> must be at least <code>strideb * (n-1) + 1</code> .
Row major	<code>ldb</code> must be at least <code>strideb * (n-1) + 1</code> .	<code>ldb</code> must be at least <code>strideb * (m-1) + 1</code> .

strideb The second stride of the matrix B. For column major layout, `strideb` is the number of elements in the array between adjacent rows of the matrix. For row major layout, `strideb` is the number of elements between adjacent columns of the matrix. In both cases `strideb` must be at least 1.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

b Pointer to output matrix B overwritten by `alpha * op(A)`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

Parent topic: *BLAS-like Extensions*

omatadd

Computes a sum of two general dense matrices, with optional transposes.

Description

The `omatadd` routine performs an out-of-place scaled matrix addition with optional transposes in the arguments. The operation is defined as:

$$C \leftarrow \alpha * op(A) + \beta * op(B)$$

where:

`op(X)` is one of `op(X) = X`, or `op(X) = XT`, or `op(X) = XH`

`alpha` and `beta` are scalars,

`A` and `B` are input matrices while `C` is an output matrix,

`C` is `m x n`,

`A` is `m x n` if the `op(A)` is not transposed or `n by m` if it is,

and `B` is `m x n` if the `op(B)` is not transposed or `n by m` if it is.

In general, `A`, `B`, and `C` should not overlap in memory, with the exception of the following in-place operations:

- `A` and `C` may point to the same memory if `op(A)` is non-transpose and `lda = ldc`;
- `B` and `C` may point to the same memory if `op(B)` is non-transpose and `ldb = ldc`.

`omatadd` supports the following precisions:

T
float
double
std::complex<float>
std::complex<double>

omatadd (Buffer Version)

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void omatadd(sycl::queue &queue,
                oneapi::mkl::transpose transa,
                oneapi::mkl::transpose transb,
                std::int64_t m,
                std::int64_t n,
                T alpha,
                sycl::buffer<T, 1> &a,
                std::int64_t lda,
                T beta,
                sycl::buffer<T, 1> &b,
                std::int64_t ldb,
```

(continues on next page)

(continued from previous page)

        sycl::buffer<T, 1> &b,
        std::int64_t ldb,
        sycl::buffer<T, 1> &c,
        std::int64_t ldc)
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies op(A), the transposition operation applied to the matrix A. See *oneMKL defined datatypes* for more details.

transb Specifies op(B), the transposition operation applied to the matrix B. See *oneMKL defined datatypes* for more details.

m Number of rows for the result matrix C. Must be at least zero.

n Number of columns for the result matrix C. Must be at least zero.

alpha Scaling factor for the matrix A.

a Buffer holding the input matrix A.

	transa = transpose::nontrans	transa = transpose::trans Or transa = transpose::conjtrans
Column major	A is m x n matrix. Size of array a must be at least lda * n	A is n x m matrix. Size of array a must be at least lda * m
Row major	A is m x n matrix. Size of array a must be at least lda * m	A is n x m matrix. Size of array a must be at least lda * n

lda The leading dimension of the matrix A. It must be positive.

	transa = transpose::nontrans	transa = transpose::trans Or transa = transpose::conjtrans
Column major	lda must be at least m.	lda must be at least n.
Row major	lda must be at least n.	lda must be at least m.

beta Scaling factor for the matrix B.

b Buffer holding the input matrix B. Must have size at least:

	<code>transb = transpose::nontrans</code>	<code>transb = transpose::trans</code> or <code>transb = transpose::conjtrans</code>
Column major	B is $m \times n$ matrix. Size of array b must be at least $ldb * n$	B is $n \times m$ matrix. Size of array b must be at least $ldb * m$
Row major	B is $m \times n$ matrix. Size of array b must be at least $ldb * m$	B is $n \times m$ matrix. Size of array b must be at least $ldb * n$

ldb The leading dimension of the B matrix. It must be positive.

	<code>transb = transpose::nontrans</code>	=	<code>transb = transpose::trans</code> or <code>transb = transpose::conjtrans</code>
Column major	ldb must be at least m.		ldb must be at least n.
Row major	ldb must be at least n.		ldb must be at least m.

c Buffer holding the output matrix C.

Column major	C is $m \times n$ matrix. Size of array c must be at least $ldc * n$
Row major	C is $m \times n$ matrix. Size of array c must be at least $ldc * m$

ldc Leading dimension of the C matrices. If matrices are stored using column major layout, ldc must be at least m. If matrices are stored using row major layout, ldc must be at least n. Must be positive.

Output Parameters

c Output buffer overwritten by $\alpha * \text{op}(A) + \beta * \text{op}(B)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

omatadd (USM Version)

Syntax

```

namespace oneapi::mkl::blas::column_major {
    sycl::event omatadd(sycl::queue &queue,
                       oneapi::mkl::transpose transa,
                       oneapi::mkl::transpose transb,
                       std::int64_t m,
                       std::int64_t n,
                       T alpha,
                       const T *a,
                       std::int64_t lda,
                       T beta,
                       const T *b,
                       std::int64_t ldb,
                       T *c,
                       std::int64_t ldc,
                       const std::vector<sycl::event> &dependencies = {});
}

```

```

namespace oneapi::mkl::blas::row_major {
    sycl::event omatadd(sycl::queue &queue,
                       oneapi::mkl::transpose transa,
                       oneapi::mkl::transpose transb,
                       std::int64_t m,

}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies op(A), the transposition operation applied to the matrix A. See *oneMKL defined datatypes* for more details.

transb Specifies op(B), the transposition operation applied to the matrix B. See *oneMKL defined datatypes* for more details.

m Number of rows for the result matrix C. Must be at least zero.

n Number of columns for the result matrix C. Must be at least zero.

alpha Scaling factor for the matrix A.

a Array holding the input matrix A.

	<code>transa = transpose::nontrans</code>	<code>transa = transpose::trans</code> Or <code>transa = transpose::conjtrans</code>
Column major	A is $m \times n$ matrix. Size of array a must be at least $lda * n$	A is $n \times m$ matrix. Size of array a must be at least $lda * m$
Row major	A is $m \times n$ matrix. Size of array a must be at least $lda * m$	A is $n \times m$ matrix. Size of array a must be at least $lda * n$

lda The leading dimension of the matrix A. It must be positive.

	<code>transa = transpose::nontrans</code>	<code>transa = transpose::trans</code> Or <code>transa = transpose::conjtrans</code>
Column major	lda must be at least m.	lda must be at least n.
Row major	lda must be at least n.	lda must be at least m.

beta Scaling factor for the matrices B.

b Array holding the input matrices B.

	<code>transb = transpose::nontrans</code>	<code>transb = transpose::trans</code> Or <code>transb = transpose::conjtrans</code>
Column major	B is $m \times n$ matrix. Size of array b must be at least $ldb * n$	B is $n \times m$ matrix. Size of array b must be at least $ldb * m$
Row major	B is $m \times n$ matrix. Size of array b must be at least $ldb * m$	B is $n \times m$ matrix. Size of array b must be at least $ldb * n$

ldb The leading dimension of the B matrix. It must be positive.

	<code>transb = transpose::nontrans</code>	<code>transb = transpose::trans</code> Or <code>transb = transpose::conjtrans</code>
Column major	ldb must be at least m.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least m.

c Array holding the output matrix C.

Column major	C is $m \times n$ matrix. Size of array c must be at least $ldc * n$
Row major	C is $m \times n$ matrix. Size of array c must be at least $ldc * m$

ldc Leading dimension of the C matrix. If matrices are stored using column major layout, ldc must be at least m. If matrices are stored using row major layout, ldc must be at least n. Must be positive.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Output array, overwritten by $\alpha * \text{op}(A) + \beta * \text{op}(B)$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

imatcopy_batch

Computes a group of in-place scaled matrix transpose or copy operations using general dense matrices.

Description

The `imatcopy_batch` routines perform a series of in-place scaled matrix copies or transpositions. They are batched versions of *imatcopy*, but the `imatcopy_batch` routines perform their operations with groups of matrices. Each group contains matrices with the same parameters.

There is a *strided API*, in which the matrices in a batch are a set distance away from each other in memory and in which all matrices share the same parameters (for example matrix size), and a more flexible *group API* where each group of matrices has the same parameters but the user may provide multiple groups that have different parameters. The group API argument structure is better suited to USM pointers than to `sycl::buffer` arguments, so we only specify it for USM inputs. The strided API works with both USM and buffer memory.

	strided API	group API
Buffer memory	supported	not supported
USM pointers	supported	supported

`imatcopy_batch` supports the following precisions:

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

imatcopy_batch (Buffer Version)

Description

The buffer version of `imatcopy_batch` supports only the strided API.

The operation for the strided API is defined as:

```

for i = 0 ... batch_size - 1
    C is a matrix at offset i * stride in matrix_array_in_out
    C := alpha * op(C)
end for

```

where:

`op(X)` is one of `op(X) = X`, or `op(X) = XT`, or `op(X) = XH`,

`alpha` is a scalar,

`C` is a matrix to be transformed in place,

and `C` is `m x n`.

The `matrix_array_in_out` buffer contains all the input matrices. The stride between matrices is given by the `stride` parameter. The total number of matrices in `matrix_array_in_out` is given by the `batch_size` parameter.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void imatcopy_batch(sycl::queue &queue,
                       oneapi::mkl::transpose trans,
                       std::int64_t m,
                       std::int64_t n,
                       T alpha,
                       sycl::buffer<T, 1> &matrix_array_in_out,
                       std::int64_t ld_in,
                       std::int64_t ld_out,
                       std::int64_t stride,
                       std::int64_t batch_size);
}

```

```

namespace oneapi::mkl::blas::row_major {
    void imatcopy_batch(sycl::queue &queue,
                       oneapi::mkl::transpose trans,
                       std::int64_t m,
                       std::int64_t n,
                       T alpha,
                       sycl::buffer<T, 1> &matrix_array_in_out,
                       std::int64_t ld_in,
                       std::int64_t ld_out,
                       std::int64_t stride,
                       std::int64_t batch_size);
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $\text{op}(C)$, the transposition operation applied to the matrices C . See *oneMKL defined datatypes* for more details.

m Number of rows of each matrix C on input. Must be at least zero.

n Number of columns of each matrix C on input. Must be at least zero.

alpha Scaling factor for the matrix transpositions or copies.

matrix_array_in_out Buffer holding the input matrices C with size $\text{stride} * \text{batch_size}$.

ld_in The leading dimension of the matrices C on input. It must be positive, and must be at least m if column major layout is used, and at least n if row-major layout is used.

ld_out The leading dimension of the matrices C on output. It must be positive.

	C not transposed	C transposed
Column major	ld_out must be at least m.	ld_out must be at least n.
Row major	ld_out must be at least n.	ld_out must be at least m.

stride Stride between different C matrices.

	C not transposed	C transposed
Column major	stride must be at least $\max(\text{ld_in} * m, \text{ld_out} * m)$.	stride must be at least $\max(\text{ld_in} * m, \text{ld_out} * n)$.
Row major	stride must be at least $\max(\text{ld_in} * n, \text{ld_out} * n)$.	stride must be at least $\max(\text{ld_in} * n, \text{ld_out} * m)$.

batch_size Specifies the number of matrix transposition or copy operations to perform.

Output Parameters

matrix_array_in_out Output buffer, overwritten by batch_size matrix copy or transposition operations of the form $\alpha * \text{op}(C)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

imatcopy_batch (USM Version)

Description

The USM version of `imatcopy_batch` supports the group API and the strided API.

The operation for the group API is defined as:

```

idx = 0
for i = 0 ... group_count - 1
    m,n, alpha, ld_in, ld_out and group_size at position i in their respective arrays
    for j = 0 ... group_size - 1
        C is a matrix at position idx in matrix_array_in_out
        C := alpha * op(C)
        idx := idx + 1
    end for
end for
end for

```

The operation for the strided API is defined as:

```

for i = 0 ... batch_size - 1
    C is a matrix at offset i * stride in matrix_array_in_out
    C := alpha * op(C)
end for

```

where:

$op(X)$ is one of $op(X) = X$, or $op(X) = X^T$, or $op(X) = X^H$,

α is a scalar,

C is a matrix to be transformed in place,

and C is $m \times n$.

For the group API, the matrices are given by arrays of pointers. C represents a matrix stored at the address pointed to by `matrix_array_in_out`. The number of entries in `matrix_array_in_out` is given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For the strided API, the single array C contains all the matrices to be transformed in place. The locations of the individual matrices within the buffer or array are given by stride lengths, while the number of matrices is given by the `batch_size` parameter.

Group API

Syntax

```

namespace oneapi::mkl::blas::column_major {
    event imatcopy_batch(sycl::queue &queue,
                        const oneapi::mkl::transpose *trans_array,
                        const std::int64_t *m_array,
                        const std::int64_t *n_array,
                        const T *alpha_array,
                        T **matrix_array_in_out,

```

(continues on next page)

(continued from previous page)

```

    const std::int64_t *ld_in_array,
    const std::int64_t *ld_out_array,
    std::int64_t group_count,
    const std::int64_t *groupsize,
    const std::vector<sycl::event> &dependencies = {});
}

```

```

namespace oneapi::mkl::blas::row_major {
    event imatcopy_batch(sycl::queue &queue,
        const oneapi::mkl::transpose *trans_array,
        const std::int64_t *m_array,
        const std::int64_t *n_array,
        const T *alpha_array,
        T **matrix_array_in_out,
        const std::int64_t *ld_in_array,
        const std::int64_t *ld_out_array,
        std::int64_t group_count,
        const std::int64_t *groupsize,
        const std::vector<sycl::event> &dependencies = {});
}

```

Input Parameters

queue The queue where the routine should be executed.

trans_array Array of size `group_count`. Each element `i` in the array specifies `op(C)` the transposition operation applied to the matrices `C`.

m_array Array of size `group_count` of number of rows of `C` on input. Each must be at least 0.

n_array Array of size `group_count` of number of columns of `C` on input. Each must be at least 0.

alpha_array Array of size `group_count` containing scaling factors for the matrix transpositions or copies.

matrix_array_in_out Array of size `total_batch_count`, holding pointers to arrays used to store `C` matrices.

ld_in_array Array of size `group_count`. The leading dimension of the matrix input `C`. If matrices are stored using column major layout, `ld_in_array[i]` must be at least `m_array[i]`. If matrices are stored using row major layout, `ld_in_array[i]` must be at least `n_array[i]`. Must be positive.

ld_out_array Array of size `group_count`. The leading dimension of the output matrix `C`. Each entry `ld_out_array[i]` must be positive and at least:

- `m_array[i]` if column major layout is used and `C` is not transposed
- `m_array[i]` if row major layout is used and `C` is transposed
- `n_array[i]` otherwise

group_count Number of groups. Must be at least 0.

group_size Array of size `group_count`. The element `group_size[i]` is the number of matrices in the group `i`. Each element in `group_size` must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

matrix_array_in_out Output array of pointers to C matrices, overwritten by total_batch_count matrix transpose or copy operations of the form $\alpha * op(C)$.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event imatcopy_batch(sycl::queue &queue,
                             oneapi::mkl::transpose trans,
                             std::int64_t m,
                             std::int64_t n,
                             T alpha,
                             const T *matrix_array_in_out,
                             std::int64_t ld_in,
                             std::int64_t ld_out,
                             std::int64_t stride,
                             std::int64_t batch_size,
                             const std::vector<sycl::event> &dependencies = {});
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event imatcopy_batch(sycl::queue &queue,
                              oneapi::mkl::transpose trans,
                              std::int64_t m,
                              std::int64_t n,
                              T alpha,
                              const T *matrix_array_in_out,
                              std::int64_t ld_in,
                              std::int64_t ld_out,
                              std::int64_t stride,
                              std::int64_t batch_size,
                              const std::vector<sycl::event> &dependencies = {});
}
```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(C)$, the transposition operation applied to the matrices C.

m Number of rows for each matrix C on input. Must be at least 0.

n Number of columns for each matrix C on input. Must be at least 0.

alpha Scaling factor for the matrix transpose or copy operation.

matrix_array_in_out Array holding the matrices C. Must have size at least $stride * batch_size$.

ld_in Leading dimension of the C matrices on input. If matrices are stored using column major layout, `ld_in` must be at least `m`. If matrices are stored using row major layout, `ld_in` must be at least `n`. Must be positive.

ld_out Leading dimension of the C matrices on output. If matrices are stored using column major layout, `ld_out` must be at least `m` if C is not transposed or `n` if C is transposed. If matrices are stored using row major layout, `ld_out` must be at least `n` if C is not transposed or at least `m` if C is transposed. Must be positive.

stride Stride between different C matrices within `matrix_array_in_out`.

	C not transposed	C transposed
Column major	stride must be at least $\max(\text{ld_in} * m, \text{ld_out} * m)$.	stride must be at least $\max(\text{ld_in} * m, \text{ld_out} * n)$.
Row major	stride must be at least $\max(\text{ld_in} * n, \text{ld_out} * n)$.	stride must be at least $\max(\text{ld_in} * n, \text{ld_out} * m)$.

batch_size Specifies the number of matrices to transpose or copy.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

matrix_array_in_out Output array, overwritten by `batch_size` matrix transposition or copy operations of the form $\alpha * \text{op}(C)$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

Parent topic: *BLAS-like Extensions*

omatcopy_batch

Computes a group of out-of-place scaled matrix transpose or copy operations using general dense matrices.

Description

The `omatcopy_batch` routines perform a series of out-of-place scaled matrix copies or transpositions. They are batched versions of `omatcopy`, but the `omatcopy_batch` routines perform their operations with groups of matrices. Each group contains matrices with the same parameters.

There is a *strided API*, in which the matrices in a batch are a set distance away from each other in memory and in which all matrices share the same parameters (for example matrix size), and a more flexible *group API* where each group of matrices has the same parameters but the user may provide multiple groups that have different parameters. The group API argument structure is better suited to USM pointers than to `sycl::buffer` arguments, so we only specify it for USM inputs. The strided API works with both USM and buffer memory.

	strided API	group API
Buffer memory	supported	not supported
USM pointers	supported	supported

`omatcopy_batch` supports the following precisions:

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

`omatcopy_batch` (Buffer Version)

Description

The buffer version of `omatadd_batch` supports only the strided API.

The operation for the strided API is defined as:

```
for i = 0 ... batch_size - 1
  A and B are matrices at offset i * stridea in a and i * strideb in b
  B := alpha * op(A)
end for
```

where:

`op(X)` is one of `op(X) = X`, or `op(X) = XT`, or `op(X) = XH`,

`alpha` is a scalar,

`A` and `B` are input and output matrices,

`A` is `m x n`,

and `B` is `m x n` if the matrix is not transposed or `n by m` if it is.

The `a` buffer contains all the input matrices while the `b` buffer contains all the output matrices. The locations of the individual matrices within the buffer are given by the `stride_a` and `stride_b` parameters, while the total number of matrices in each buffer is given by the `batch_size` parameter.

Strided API

Syntax

```

namespace oneapi::mkl::blas::column_major {
    void omatcopy_batch(sycl::queue &queue,
                       oneapi::mkl::transpose trans,
                       std::int64_t m,
                       std::int64_t n,
                       T alpha,
                       sycl::buffer<T, 1> &a,
                       std::int64_t lda,
                       std::int64_t stride_a,
                       sycl::buffer<T, 1> &b,
                       std::int64_t ldb,
                       std::int64_t stride_b,
                       std::int64_t batch_size);
}

```

```

namespace oneapi::mkl::blas::row_major {
    void omatcopy_batch(sycl::queue &queue,
                       oneapi::mkl::transpose trans,
                       std::int64_t m,
                       std::int64_t n,
                       T alpha,
                       sycl::buffer<T, 1> &a,
                       std::int64_t lda,
                       std::int64_t stride_a,
                       sycl::buffer<T, 1> &b,
                       std::int64_t ldb,
                       std::int64_t stride_b,
                       std::int64_t batch_size);
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Specifies $op(A)$, the transposition operation applied to the matrices **A**. See *oneMKL defined datatypes* for more details.

m Number of rows for each matrix **A**. Must be at least zero.

n Number of columns for each matrix **A**. Must be at least zero.

alpha Scaling factor for the matrix transposition or copy operations.

a Buffer holding the input matrices **A** with size `stride_a * batch_size`.

lda The leading dimension of the matrices **A**. It must be positive, and must be at least **m** if column major layout is used, and at least **n** if row-major layout is used.

stride_a Stride between the different **A** matrices. If matrices are stored using column major layout, **stride_a** must be at least `lda*n`. If matrices are stored using row major layout, **stride_a** must be at least `lda*m`.

b Buffer holding the output matrices **B** with size `stride_b * batch_size`.

ldb The leading dimension of the matrices **B**. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least m.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least m.

stride_b Stride between different B matrices.

	B not transposed	B transposed
Column major	stride_b must be at least ldb x n.	stride_b must be at least ldb x m.
Row major	stride_b must be at least ldb x m.	stride_b must be at least ldb x n.

batch_size Specifies the number of matrix transposition or copy operations to perform.

Output Parameters

b Output buffer, overwritten by batch_size matrix copy or transposition operations of the form $\alpha * \text{op}(A)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

omatcopy_batch (USM Version)

Description

The USM version of `omatcopy_batch` supports the group API and the strided API.

The operation for the group API is defined as:

```

idx = 0
for i = 0 ... group_count - 1
  m, n, alpha, lda, ldb and group_size at position i in their respective arrays
  for j = 0 ... group_size - 1
    A and B are matrices at position idx in their respective arrays
    B := alpha * op(A)
    idx := idx + 1
  end for
end for
end for

```

The operation for the strided API is defined as:

```

for i = 0 ... batch_size - 1
  A and B are matrices at offset i * stridea in a and i * strideb in b
  B := alpha * op(A)
end for

```

where:

op(X) is one of op(X) = X, or op(X) = X^T, or op(X) = X^H,

alpha is a scalar,

A and B are input and output matrices,

A is m x n,

and B is m x n if the matrix is not transposed or n by m if it is.

For the group API, the matrices are given by arrays of pointers. A and B represent matrices stored at addresses pointed to by a_array and b_array respectively. The number of entries in a_array and b_array is given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For the strided API, the single input array contains all the input matrices, and the single output array contains all the output matrices. The locations of the individual matrices within the array are given by stride lengths, while the number of matrices is given by the batch_size parameter.

Group API

Syntax

```

namespace oneapi::mkl::blas::column_major {
  sycl::event omatcopy_batch(sycl::queue &queue,
    const oneapi::mkl::transpose *trans_array,
    const std::int64_t *m_array,
    const std::int64_t *n_array,
    const T *alpha_array,
    const T **a_array,
    const std::int64_t *lda_array,
    T **b_array,
    const std::int64_t *ldb_array,
    std::int64_t group_count,
    const std::int64_t *groupsize,
    const std::vector<sycl::event> &dependencies = {});
}

```

```

namespace oneapi::mkl::blas::row_major {
  sycl::event omatcopy_batch(sycl::queue &queue,
    const oneapi::mkl::transpose *trans_array,
    const std::int64_t *m_array,
    const std::int64_t *n_array,
    const T *alpha_array,
    const T **a_array,
    const std::int64_t *lda_array,
    T **b_array,

```

(continues on next page)

(continued from previous page)

```

    const std::int64_t *ldb_array,
    std::int64_t group_count,
    const std::int64_t *groupsize,
    const std::vector<sycl::event> &dependencies = {});
}

```

Input Parameters

queue The queue where the routine should be executed.

trans_array Array of size `group_count`. Each element `i` in the array specifies `op(A)` the transposition operation applied to the matrices `A`.

m_array Array of size `group_count` of number of rows of `A`. Each must be at least 0.

n_array Array of size `group_count` of number of columns of `A`. Each must be at least 0.

alpha_array Array of size `group_count` containing scaling factors for the matrix transpositions or copies.

a_array Array of size `total_batch_count`, holding pointers to arrays used to store `A` matrices.

lda_array Array of size `group_count` of leading dimension of the `A` matrices. If matrices are stored using column major layout, `lda_array[i]` must be at least `m_array[i]`. If matrices are stored using row major layout, `lda_array[i]` must be at least `n_array[i]`. Each must be positive.

b_array Array of size `total_batch_count` of pointers used to store `B` matrices. The array allocated for each `B` matrix of the group `i` must be of size at least:

	B not transposed	B transposed
Column major	<code>ldb_array[i] x n_array[i]</code>	<code>ldb_array[i] x m_array[i]</code>
Row major	<code>ldb_array[i] x m_array[i]</code>	<code>ldb_array[i] x n_array[i]</code>

ldb_array Array of size `group_count`. The leading dimension of the output matrix `B`. Each entry `ldb_array[i]` must be positive and at least:

	B not transposed	B transposed
Column major	<code>ldb[i]</code> must be at least <code>m_array[i]</code> .	<code>ldb[i]</code> must be at least <code>n_array[i]</code> .
Row major	<code>ldb[i]</code> must be at least <code>n_array[i]</code> .	<code>ldb[i]</code> must be at least <code>m_array[i]</code> .

group_count Number of groups. Must be at least 0.

group_size Array of size `group_count`. The element `group_size[i]` is the number of matrices in the group `i`. Each element in `group_size` must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

b_array Output array of pointers to B matrices, overwritten by total_batch_count matrix transpose or copy operations of the form $\alpha * \text{op}(A)$.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    event omatcopy_batch(queue &queue,
        transpose trans,
        std::int64_t m,
        std::int64_t n,
        T alpha,
        const T *a,
        std::int64_t lda,
        std::int64_t stride_a,
        T *b,
        std::int64_t ldb,
        std::int64_t stride_b,
        std::int64_t batch_size,
        const std::vector<sycl::event> &dependencies = {});
}
```

```
namespace oneapi::mkl::blas::row_major {
    event omatcopy_batch(queue &queue,
        transpose trans,
        std::int64_t m,
        std::int64_t n,
        T alpha,
        const T *a,
        std::int64_t lda,
        std::int64_t stride_a,
        T *b,
        std::int64_t ldb,
        std::int64_t stride_b,
        std::int64_t batch_size,
        const vector_class<event> &dependencies = {});
}
```

Input Parameters

queue The queue where the routine will be executed.

trans Specifies $\text{op}(A)$, the transposition operation applied to the matrices A .

m Number of rows for each matrix A . Must be at least 0.

n Number of columns for each matrix B . Must be at least 0.

alpha Scaling factor for the matrix transpose or copy operation.

a Array holding the matrices A . Must have size at least $\text{stride_a} \times \text{batch_size}$.

lda Leading dimension of the A matrices. If matrices are stored using column major layout, lda must be at least m . If matrices are stored using row major layout, lda must be at least n . Must be positive.

stride_a Stride between the different A matrices. If matrices are stored using column major layout, stride_a must be at least $\text{lda} \times n$. If matrices are stored using row major layout, stride_a must be at least $\text{lda} \times m$.

b Array holding the matrices B . Must have size at least $\text{stride_b} \times \text{batch_size}$.

ldb Leading dimension of the B matrices. Must be positive.

	B not transposed	B transposed
Column major	ldb must be at least m .	ldb must be at least n .
Row major	ldb must be at least n .	ldb must be at least m .

stride_b Stride between different B matrices.

	B not transposed	B transposed
Column major	stride_b must be at least $\text{ldb} \times n$.	stride_b must be at least $\text{ldb} \times m$.
Row major	stride_b must be at least $\text{ldb} \times m$.	stride_b must be at least $\text{ldb} \times n$.

batch_size Specifies the number of matrices to transpose or copy.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

b Output array, overwritten by batch_size matrix transposition or copy operations of the form $\text{alpha} \times \text{op}(A)$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

omatadd_batch

Computes a group of out-of-place scaled matrix additions using general dense matrices.

Description

The `omatadd_batch` routines perform a series of out-of-place scaled matrix additions. They are batched versions of *omatadd*, but the `omatadd_batch` routines perform their operations with groups of matrices. Each group contains matrices with the same parameters.

There is a *strided API*, in which the matrices in a batch are a set distance away from each other in memory and in which all matrices share the same parameters (for example matrix size), and a more flexible *group API* where each group of matrices has the same parameters but the user may provide multiple groups that have different parameters. The group API argument structure is better suited to USM pointers than to `sycl::buffer` arguments, so we only specify it for USM inputs. The strided API works with both USM and buffer memory.

	strided API	group API
Buffer memory	supported	not supported
USM pointers	supported	supported

`omatadd_batch` supports the following precisions:

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

omatadd_batch (Buffer Version)

Description

The buffer version of `omatcopy_batch` supports only the strided API.

The operation of `omatadd_batch` is defined as:

```
for i = 0 ... batch_size - 1
  A is a matrix at offset i * stridea in a
  B is a matrix at offset i * strideb in b
  C is a matrix at offset i * stridec in c
  C := alpha * op(A) + beta * op(B)
end for
```

where:

$\text{op}(X)$ is one of $\text{op}(X) = X$, or $\text{op}(X) = X^T$, or $\text{op}(X) = X^H$,

alpha and beta are scalars,

A and B are input matrices while C is an output matrix,

C is $m \times n$,

A is $m \times n$ if the `op(A)` is not transposed or n by m if it is,

and B is $m \times n$ if the `op(B)` is not transposed or n by m if it is.

The `a` and `b` buffers contain all the input matrices while the `c` buffer contains all the output matrices. The locations of the individual matrices within the buffer are given by the `stride_a`, `stride_b`, and `stride_c` parameters, while the total number of matrices in each buffer is given by the `batch_size` parameter.

In general, the `a`, `b`, and `c` buffers should not overlap in memory, with the exception of the following in-place operations:

- `a` and `c` may point to the same memory if `op(A)` is non-transpose and all the A matrices have the same parameters as all the respective C matrices;
- `b` and `c` may point to the same memory if `op(B)` is non-transpose and all the B matrices have the same parameters as all the respective C matrices.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    void omatadd_batch(sycl::queue &queue,
                      oneapi::mkl::transpose transa,
                      oneapi::mkl::transpose transb,
                      std::int64_t m,
                      std::int64_t n,
                      T alpha,
                      sycl::buffer<T, 1> &a,
                      std::int64_t lda,
                      std::int64_t stride_a,
                      T beta,
                      sycl::buffer<T, 1> &b,
                      std::int64_t ldb,
                      std::int64_t stride_b,
                      sycl::buffer<T, 1> &c,
                      std::int64_t ldc,
                      std::int64_t stride_c,
                      std::int64_t batch_size);
}
```

```
namespace oneapi::mkl::blas::row_major {

                      oneapi::mkl::transpose transa,
                      oneapi::mkl::transpose transb,
                      std::int64_t m,
                      std::int64_t n,
                      T alpha,
                      sycl::buffer<T, 1> &a,
                      std::int64_t lda,
                      std::int64_t stride_a,
                      T beta,
                      sycl::buffer<T, 1> &b,
```

(continues on next page)

(continued from previous page)

```

std::int64_t ldb,
std::int64_t stride_b,
sycl::buffer<T, 1> &c,
std::int64_t ldc,
std::int64_t stride_c,
std::int64_t batch_size);
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies $\text{op}(A)$, the transposition operation applied to the matrices A. See *oneMKL defined datatypes* for more details.

transb Specifies $\text{op}(B)$, the transposition operation applied to the matrices B. See *oneMKL defined datatypes* for more details.

m Number of rows for the result matrix C. Must be at least zero.

n Number of columns for the result matrix C. Must be at least zero.

alpha Scaling factor for the matrices A.

a Buffer holding the input matrices A. Must have size at least $\text{stride_a} * \text{batch_size}$.

lda The leading dimension of the matrices A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least m.	lda must be at least n.
Row major	lda must be at least n.	lda must be at least m.

stride_a Stride between the different A matrices within the buffer.

	A not transposed	A transposed
Column major	stride_a must be at least $\text{lda} * \text{n}$.	stride_a must be at least $\text{lda} * \text{m}$.
Row major	stride_a must be at least $\text{lda} * \text{m}$.	stride_a must be at least $\text{lda} * \text{n}$.

beta Scaling factor for the matrices B.

b Buffer holding the input matrices B. Must have size at least $\text{stride_b} * \text{batch_size}$.

ldb The leading dimension of the B matrices. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least m.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least m.

stride_b Stride between different B matrices.

	B not transposed	B transposed
Column major	stride_b must be at least $\text{ldb} * \text{n}$.	stride_b must be at least $\text{ldb} * \text{m}$.
Row major	stride_b must be at least $\text{ldb} * \text{m}$.	stride_b must be at least $\text{ldb} * \text{n}$.

c Buffer holding the output matrices C. Must have size at least `stride_c * batch_size`.

ldc Leading dimension of the C matrices. If matrices are stored using column major layout, ldc must be at least m. If matrices are stored using row major layout, ldc must be at least n. Must be positive.

stride_c Stride between the different C matrices. If matrices are stored using column major layout, `stride_c` must be at least `ldc*n`. If matrices are stored using row major layout, `stride_c` must be at least `ldc*m`.

batch_size Specifies the number of matrix transposition or copy operations to perform.

Output Parameters

c Output buffer, overwritten by `batch_size` matrix addition operations of the form $\alpha * \text{op}(A) + \beta * \text{op}(B)$. Must have size at least `stride_c*batch_size`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

omatadd_batch (USM Version)

Description

The USM version of `omatadd_batch` supports the group API and the strided API.

The operation for the group API is defined as:

```

idx = 0
for i = 0 ... group_count - 1
    m, n, alpha, beta, lda, ldb, ldc and group_size at position i in their respective
    ↪ arrays
    for j = 0 ... group_size - 1
        A, B and C are matrices at position idx in their respective arrays
        C := alpha * op(A) + beta * op(B)
        idx := idx + 1
    end for
end for
end for

```

The operation for the strided API is defined as:

```

for i = 0 ... batch_size - 1
    A is a matrix at offset i * stridea in a
    B is a matrix at offset i * strideb in b
    C is a matrix at offset i * stridec in c

```

(continues on next page)

(continued from previous page)

```
C := alpha * op(A) + beta * op(B)
end for
```

where:

op(X) is one of op(X) = X, or op(X) = X^T, or op(X) = X^H,

alpha and beta are scalars,

A and B are input matrices while C is an output matrix,

C is m x n,

A is m x n if the op(A) is not transposed or n by m if it is,

and B is m x n if the op(B) is not transposed or n by m if it is.

For the group API, the matrices are given by arrays of pointers. A, B, and C represent matrices stored at addresses pointed to by a_array, b_array, and c_array respectively. The number of entries in a_array, b_array, and c_array is given by:

$$total_batch_count = \sum_{i=0}^{group_count-1} group_size[i]$$

For the strided API, the a and b arrays contain all the input matrices while the c array contains all the output matrices. The locations of the individual matrices within the array are given by the stride_a, stride_b, and stride_c parameters, while the total number of matrices in each array is given by the batch_size parameter.

In general, the batches of matrices indicated by a, b, and c should not overlap in memory, with the exception of the the following in-place operations:

- a and c may point to the same memory if op(A) is non-transpose and all the A matrices have identical parameters as all the respective C matrices;
- b and c may point to the same memory if op(B) is non-transpose and all the the B matrices have identical parameters as all the respective C matrices.

Group API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event omatadd_batch(sycl::queue &queue,
                            const oneapi::mkl::transpose *transa_array,
                            const oneapi::mkl::transpose *transb_array,
                            const std::int64_t *m_array,
                            const std::int64_t *n_array,
                            const T *alpha_array,
                            const T **a_array,
                            const std::int64_t *lda_array,
                            const T *beta_array,
                            const T **b_array,
                            const std::int64_t *ldb_array,
                            const T **c_array,
                            const std::int64_t *ldc_array,
                            std::int64_t group_count,
```

(continues on next page)

(continued from previous page)

```

        const std::int64_t *n_array,
        const T *alpha_array,
        const T **a_array,
        const std::int64_t *lda_array,
        const T *beta_array,
        const T **b_array,
        const std::int64_t *ldb_array,
        const T **c_array,
        const std::int64_t *ldc_array,
        std::int64_t group_count,
        const std::int64_t *groupsize,
        const std::vector<sycl::event> &dependencies = {});
}

```

Input Parameters

queue The queue where the routine should be executed.

transa_array Array of size `group_count`. Each element `i` in the array specifies `op(A)` the transposition operation applied to the matrices A.

transb_array Array of size `group_count`. Each element `i` in the array specifies `op(B)` the transposition operation applied to the matrices B.

m_array Array of size `group_count` of number of rows of C. Each must be at least 0.

n_array Array of size `group_count` of number of columns of C. Each must be at least 0.

alpha_array Array of size `group_count` containing scaling factors for the matrices A.

a_array Array of size `total_batch_count`, holding pointers to arrays used to store A matrices. The array allocated for each A matrix of the group `i` must be of size at least:

	<code>transa[i]</code> <code>transpose::nontrans</code>	=	<code>transa[i] = transpose::trans</code> or <code>transa[i] = transpose::conjtrans</code>
Column major	<code>lda_array[i]</code> <code>n_array[i]</code>	*	<code>lda_array[i] * m_array[i]</code>
Row major	<code>lda_array[i]</code> <code>m_array[i]</code>	*	<code>lda_array[i] * n_array[i]</code>

lda_array Array of size `group_count` of leading dimension of the A matrices. All must be positive and satisfy:

	transa[i] = transpose::nontrans	transa[i] = transpose::trans or transa = transpose::conjtrans
Column major	lda_array[i] must be at least m_array[i].	lda_array[i] must be at least n_array[i].
Row major	lda_array[i] must be at least n_array[i].	lda_array[i] must be at least m_array[i].

beta_array Array of size group_count containing scaling factors for the matrices B.

b_array Array of size total_batch_count of pointers used to store the B matrices. The array allocated for each B matrix of the group i must be of size at least:

	transb[i] = transpose::nontrans	transb[i] = transpose::trans or transb[i] = transpose::conjtrans
Column major	ldb_array[i] * n_array[i]	ldb_array[i] * m_array[i]
Row major	ldb_array[i] * m_array[i]	ldb_array[i] * n_array[i]

ldb_array Array of size group_count. The leading dimension of B matrices. All must be positive and satisfy:

	transb[i] = transpose::nontrans	transb[i] = transpose::trans or transb[i] = transpose::conjtrans
Column major	ldb_array[i] must be at least m_array[i].	ldb_array[i] must be at least n_array[i].
Row major	ldb_array[i] must be at least n_array[i].	ldb_array[i] must be at least m_array[i].

c_array Array of size total_batch_count of pointers used to store the C output matrices. The array allocated for each C matrix of the group i must be of size at least:

Column major	ldc_array[i] * n_array[i]
Row major	ldc_array[i] * m_array[i]

ldc_array Array of size group_count. The leading dimension of the C matrices. If matrices are stored using column major layout, ldc_array[i] must be at least m_array[i]. If matrices are stored using row major layout, ldc_array[i] must be at least n_array[i]. All entries must be positive.

group_count Number of groups. Must be at least 0.

group_size Array of size group_count. The element group_size[i] is the number of matrices in the group i. Each element in group_size must be at least 0.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c_array Output array of pointers to C matrices, overwritten by total_batch_count matrix addition operations of the form $\alpha * \text{op}(A) + \beta * \text{op}(B)$.

Return Values

Output event to wait on to ensure computation is complete.

Strided API

Syntax

```
namespace oneapi::mkl::blas::column_major {
    sycl::event omatadd_batch(sycl::queue &queue,
                            oneapi::mkl::transpose transa,
                            oneapi::mkl::transpose transb,
                            std::int64_t m,
                            std::int64_t n,
                            T alpha,
                            const T *a,
                            std::int64_t lda,
                            std::int64_t stride_a,
                            T beta,
                            T *b,
                            std::int64_t ldb,
                            std::int64_t stride_b,
                            T *c,
                            std::int64_t ldc,
                            std::int64_t stride_c,
                            std::int64_t batch_size,
                            const std::vector<sycl::event> &dependencies = {});
}
```

```
namespace oneapi::mkl::blas::row_major {
    sycl::event omatadd_batch(sycl::queue &queue,
                              oneapi::mkl::transpose transa,
                              oneapi::mkl::transpose transb,
                              std::int64_t m,
                              std::int64_t n,
                              T alpha,
                              const T *a,
                              std::int64_t lda,
                              std::int64_t stride_a,
                              T beta,
                              T *b,
                              std::int64_t ldb,
                              std::int64_t stride_b,
                              T *c,
                              std::int64_t ldc,
                              std::int64_t stride_c,
                              std::int64_t batch_size,
```

(continues on next page)

(continued from previous page)

```

}
    const std::vector<sycl::event> &dependencies = {});
}

```

Input Parameters

queue The queue where the routine should be executed.

transa Specifies $op(A)$, the transposition operation applied to the matrices A. See *oneMKL defined datatypes* for more details.

transb Specifies $op(B)$, the transposition operation applied to the matrices B. See *oneMKL defined datatypes* for more details.

m Number of rows for the result matrix C. Must be at least zero.

n Number of columns for the result matrix C. Must be at least zero.

alpha Scaling factor for the matrices A.

a Array holding the input matrices A. Must have size at least $stride_a * batch_size$.

lda The leading dimension of the matrices A. It must be positive.

	A not transposed	A transposed
Column major	lda must be at least m.	lda must be at least n.
Row major	lda must be at least n.	lda must be at least m.

stride_a Stride between the different A matrices within the array.

	A not transposed	A transposed
Column major	stride_a must be at least $lda * n$.	stride_a must be at least $lda * m$.
Row major	stride_a must be at least $lda * m$.	stride_a must be at least $lda * n$.

beta Scaling factor for the matrices B.

b Array holding the input matrices B. Must have size at least $stride_b * batch_size$.

ldb The leading dimension of the B matrices. It must be positive.

	B not transposed	B transposed
Column major	ldb must be at least m.	ldb must be at least n.
Row major	ldb must be at least n.	ldb must be at least m.

stride_b Stride between different B matrices.

	B not transposed	B transposed
Column major	stride_b must be at least $ldb * n$.	stride_b must be at least $ldb * m$.
Row major	stride_b must be at least $ldb * m$.	stride_b must be at least $ldb * n$.

c Array holding the output matrices C. Must have size at least $stride_c * batch_size$.

ldc Leading dimension of the C matrices. If matrices are stored using column major layout, ldc must be at least m. If matrices are stored using row major layout, ldc must be at least n. Must be positive.

stride_c Stride between the different C matrices. If matrices are stored using column major layout, `stride_c` must be at least `ldc*n`. If matrices are stored using row major layout, `stride_c` must be at least `ldc*m`.

batch_size Specifies the number of matrix transposition or copy operations to perform.

dependencies List of events to wait for before starting computation, if any. If omitted, defaults to no dependencies.

Output Parameters

c Output array, overwritten by `batch_size` matrix addition operations of the form $\alpha * \text{op}(A) + \beta * \text{op}(B)$. Must have size at least `stride_c*batch_size`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::invalid_argument

oneapi::mkl::unsupported_device

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

LAPACK Routines

oneMKL provides a DPC++ interface to select routines from the Linear Algebra PACKage (LAPACK), as well as several LAPACK-like extension routines.

LAPACK Linear Equation Routines

LAPACK Linear Equation routines are used for factoring a matrix, solving a system of linear equations, solving linear least squares problems, and inverting a matrix. The following table lists the LAPACK Linear Equation routine groups.

Routines	Scratchpad Size Routines	Description
<i>geqrf</i>	<i>geqrf_scratchpad_size</i>	Computes the QR factorization of a general m -by- n matrix.
<i>gerqf</i>	<i>gerqf_scratchpad_size</i>	Computes the RQ factorization of a general m -by- n matrix.
<i>getrf</i>	<i>getrf_scratchpad_size</i>	Computes the LU factorization of a general m -by- n matrix.
<i>getri</i>	<i>getri_scratchpad_size</i>	Computes the inverse of an LU-factored general matrix.
<i>getrs</i>	<i>getrs_scratchpad_size</i>	Solves a system of linear equations with an LU-factored square coefficient matrix, with multiple right-hand sides.
<i>hetrf</i>	<i>hetrf_scratchpad_size</i>	Computes the Bunch-Kaufman factorization of a complex Hermitian matrix.
<i>orgqr</i>	<i>orgqr_scratchpad_size</i>	Generates the real orthogonal matrix Q of the QR factorization formed by <i>geqrf</i> .
<i>ormqr</i>	<i>ormqr_scratchpad_size</i>	Multiplies a real matrix by the orthogonal matrix Q of the QR factorization formed by <i>geqrf</i> .
<i>ormrq</i>	<i>ormrq_scratchpad_size</i>	Multiplies a real matrix by the orthogonal matrix Q of the RQ factorization formed by <i>gerqf</i> .
<i>potrf</i>	<i>potrf_scratchpad_size</i>	Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix.
<i>potri</i>	<i>potri_scratchpad_size</i>	Computes the inverse of a Cholesky-factored symmetric (Hermitian) positive-definite matrix.
<i>potrs</i>	<i>potrs_scratchpad_size</i>	Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite coefficient matrix, with multiple right-hand sides.
<i>sytrf</i>	<i>sytrf_scratchpad_size</i>	Computes the Bunch-Kaufman factorization of a symmetric matrix.
<i>trtrs</i>	<i>trtrs_scratchpad_size</i>	Solves a system of linear equations with a triangular coefficient matrix, with multiple right-hand sides.
<i>ungqr</i>	<i>ungqr_scratchpad_size</i>	Generates the complex unitary matrix Q of the QR factorization formed by <i>geqrf</i> .
<i>unmqr</i>	<i>unmqr_scratchpad_size</i>	Multiplies a complex matrix by the unitary matrix Q of the QR factorization formed by <i>geqrf</i> .
<i>unmrq</i>	<i>unmrq_scratchpad_size</i>	Multiplies a complex matrix by the unitary matrix Q of the RQ factorization formed by <i>gerqf</i> .

geqrf

Computes the QR factorization of a general $m \times n$ matrix.

Description

geqrf supports the following precisions:

T
float
double
std::complex<float>
std::complex<double>

The routine forms the QR factorization of a general $m \times n$ matrix A . No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

geqrf (Buffer Version)

Syntax

```

namespace oneapi::mkl::lapack {
    void geqrf(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, cl::sycl::buffer<T,
    ↪ 1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &scratchpad,
    ↪ std::int64_t scratchpad_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in A ($0 \leq n$).

a Buffer holding input matrix A . Must have size at least $lda \cdot n$.

lda The leading dimension of A ; at least $\max(1, m)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `geqrf_scratchpad_size` function.

Output Parameters

a Output buffer, overwritten by the factorization data as follows:

The elements on and above the diagonal of the array contain the $\min(m, n) \times n$ upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array tau, represent the orthogonal matrix Q as a product of $\min(m, n)$ elementary reflectors.

tau Output buffer, size at least $\max(1, \min(m, n))$. Contains scalars that define elementary reflectors for the matrix Q in its decomposition in a product of elementary reflectors.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

geqrf (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event geqrf(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, T *a,
↳std::int64_t lda, T *tau, T *scratchpad, std::int64_t scratchpad_size, const_
↳std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in A ($0 \leq n$).

a Pointer to memory holding input matrix A . Must have size at least $lda \cdot n$.

lda The leading dimension of A ; at least $\max(1, m)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `geqrf_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by the factorization data as follows:

The elements on and above the diagonal of the array contain the $\min(m, n) \times n$ upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array `tau`, represent the orthogonal matrix Q as a product of $\min(m, n)$ elementary reflectors.

tau Array, size at least $\max(1, \min(m, n))$. Contains scalars that define elementary reflectors for the matrix Q in its decomposition in a product of elementary reflectors.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the *i*-th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

geqrf_scratchpad_size

Computes size of scratchpad memory required for *geqrf* function.

Description

`geqrf_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *geqrf* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t geqrf_scratchpad_size(cl::sycl::queue &queue, std::int64_t m, std::int64_t
    ↪ n, std::int64_t lda)
}
```

Input Parameters

queue Device queue where calculations by *geqrf* function will be performed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

lda The leading dimension of a .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *geqrf* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

gerqf

Computes the RQ factorization of a general $m \times n$ matrix.

Description

gerqf supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine forms the RQ factorization of a general $m \times n$ matrix A . No pivoting is performed. The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation

gerqf (Buffer Version)

Syntax

```

namespace oneapi::mkl::lapack {
    void gerqf(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, cl::sycl::buffer<T> &a,
    ↪ std::int64_t lda, cl::sycl::buffer<T> &tau, cl::sycl::buffer<T> &scratchpad,
    ↪ std::int64_t scratchpad_size)
}

```

Input Parameters

queue Device queue where calculations will be performed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

a Buffer holding input matrix A . The second dimension of a must be at least $\max(1, n)$.

lda The leading dimension of a , at least $\max(1, m)$.

scratchpad Buffer holding scratchpad memory to be used by the routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by the *gerqf_scratchpad_size* function.

Output Parameters

a Output buffer, overwritten by the factorization data as follows:

If $m \leq n$, the upper triangle of the subarray $a(1:m, n-m+1:n)$ contains the $m \times m$ upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m - n)$ -th subdiagonal contain the $m \times n$ upper trapezoidal matrix R

In both cases, the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of $\min(m, n)$ elementary reflectors.

tau Array, size at least $\min(m, n)$.

Contains scalars that define elementary reflectors for the matrix Q in its decomposition in a product of elementary reflectors.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

gerqf (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event gerqf(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, T *a,
↳std::int64_t lda, T *tau, T *scratchpad, std::int64_t scratchpad_size, const_
↳std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue Device queue where calculations will be performed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

a Buffer holding input matrix A . The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`, at least $\max(1, m)$.

scratchpad Buffer holding scratchpad memory to be used by the routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by the `gerqf_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Output buffer, overwritten by the factorization data as follows:

If $m \leq n$, the upper triangle of the subarray `a(1:m, n-m+1:n)` contains the $m \times m$ upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m - n)$ -th subdiagonal contain the $m \times n$ upper trapezoidal matrix R

In both cases, the remaining elements, with the array `tau`, represent the orthogonal/unitary matrix Q as a product of $\min(m, n)$ elementary reflectors.

tau Array, size at least $\min(m, n)$.

Contains scalars that define elementary reflectors for the matrix Q in its decomposition in a product of elementary reflectors.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the *i*-th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

gerqf_scratchpad_size

Computes size of scratchpad memory required for *gerqf* function.

Description

`gerqf_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *gerqf* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

gerqf_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t gerqf_scratchpad_size(cl::sycl::queue &queue, std::int64_t m, std::int64_t
        n, std::int64_t lda)
}

```

Input Parameters

queue Device queue where calculations by the `gerqf` (buffer or USM version) function will be performed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

lda The leading dimension of a ; at least $\max(1, m)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *gerqf* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

getrf

Computes the LU factorization of a general $m \times n$ matrix.

Description

`getrf` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine computes the LU factorization of a general $m \times n$ matrix A as $A = PLU$,

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). The routine uses partial pivoting, with row interchanges.

getrf (BUFFER Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void getrf(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, cl::sycl::buffer<T,
↪ 1> &a, std::int64_t lda, cl::sycl::buffer<std::int64_t, 1> &ipiv, cl::sycl::buffer<T, 1>
↪ &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in A ($0 \leq n$).

a Buffer holding input matrix A . The buffer a contains the matrix A . The second dimension of a must be at least $\max(1, n)$.

lda The leading dimension of a .

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by *getrf_scratchpad_size* function.

Output Parameters

a Overwritten by L and U . The unit diagonal elements of L are not stored.

ipiv Array, size at least $\max(1, \min(m, n))$. Contains the pivot indices; for $1 \leq i \leq \min(m, n)$, row i was interchanged with row $\text{ipiv}(i)$.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

getrf (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event getrf(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, T *a,
    ↪ std::int64_t lda, std::int64_t *ipiv, T *scratchpad, std::int64_t scratchpad_size,
    ↪ const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in A ($0 \leq n$).

a Pointer to array holding input matrix A . The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `getrf_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by L and U . The unit diagonal elements of L are not stored.

ipiv Array, size at least $\max(1, \min(m, n))$. Contains the pivot indices; for $1 \leq i \leq \min(m, n)$, row i was interchanged with row `ipiv(i)`.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

getrf_scratchpad_size

Computes size of scratchpad memory required for *getrf* function.

Description

`getrf_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *getrf* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

getrf_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t getrf_scratchpad_size(cl::sycl::queue &queue, std::int64_t m, std::int64_t
    ↪ n, std::int64_t lda)
}

```

Input Parameters

queue Device queue where calculations by *getrf* function will be performed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in A ($0 \leq n$).

lda The leading dimension of a ($n \leq lda$).

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *getrf* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

getri

Computes the inverse of an LU-factored general matrix determined by *getrf*.

Description

getri supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine computes the inverse A^{-1} of a general matrix A . Before calling this routine, call *getrf* to factorize A .

getri (BUFFER Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void getri(cl::sycl::queue &queue, std::int64_t n, cl::sycl::buffer<T,1> &a,
    ↪std::int64_t lda, cl::sycl::buffer<std::int64_t,1> &ipiv, cl::sycl::buffer<T,1> &
    ↪scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

n The order of the matrix A ($0 \leq n$).

a The buffer a as returned by *getrf*. Must be of size at least $lda \cdot \max(1, n)$.

lda The leading dimension of a ($n \leq lda$).

ipiv The buffer as returned by *getrf*. The dimension of $ipiv$ must be at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by *getri_scratchpad_size* function.

Output Parameters

a Overwritten by the $n \times n$ matrix A .

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

getri (USM Version)

Syntax

```

namespace oneapi::mkl::lapack {
    cl::sycl::event getri(cl::sycl::queue &queue, std::int64_t n, T *a, std::int64_t lda,
↳std::int64_t *ipiv, T *scratchpad, std::int64_t scratchpad_size, const std::vector
↳<cl::sycl::event> &events = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

n The order of the matrix A ($0 \leq n$).

a The array as returned by *getrf*. Must be of size at least $lda \cdot \max(1, n)$.

lda The leading dimension of a ($n \leq lda$).

ipiv The array as returned by *getrf*. The dimension of *ipiv* must be at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by *getri_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by the $n \times n$ matrix A .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

getri_scratchpad_size

Computes size of scratchpad memory required for *getri* function.

Description

`getri_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *getri* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

getri_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t getri_scratchpad_size(cl::sycl::queue &queue, std::int64_t n, std::int64_t
    ↪ t lda)
}
```

Input Parameters

queue Device queue where calculations by *getri* function will be performed.

n The order of the matrix A ($0 \leq n$).

lda The leading dimension of a ($n \leq lda$).

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *getri* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

getrs

Solves a system of linear equations with an LU-factored square coefficient matrix, with multiple right-hand sides.

Description

getrs supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine solves for X the following systems of linear equations:

$AX = B$	if <code>trans=oneapi::mkl::transpose::nontrans</code>
$A^T X = B$	if <code>trans=oneapi::mkl::transpose::trans</code>
$A^H X = B$	if <code>trans=oneapi::mkl::transpose::conjtrans</code>

Before calling this routine, you must call *getrf* to compute the LU factorization of A .

getrs (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void getsrs(cl::sycl::queue &queue, oneapi::mkl::transpose trans, std::int64_t n,
    ↪ std::int64_t nrhs, cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer
    ↪ <std::int64_t,1> &ipiv, cl::sycl::buffer<T,1> &b, std::int64_t ldb, cl::sycl::buffer<T,
    ↪ 1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

trans Indicates the form of the equations:

If `trans=oneapi::mkl::transpose::nontrans`, then $AX = B$ is solved for X .

If `trans=oneapi::mkl::transpose::trans`, then $A^T X = B$ is solved for X .

If `trans=oneapi::mkl::transpose::conjtrans`, then $A^H X = B$ is solved for X .

n The order of the matrix A and the number of rows in matrix B ($0 \leq n$).

nrhs The number of right-hand sides ($0 \leq \text{nrhs}$).

a Buffer containing the factorization of the matrix A , as returned by *getrf*. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`.

ipiv Array, size at least $\max(1, n)$. The `ipiv` array, as returned by *getrf*.

b The array `b` contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of `b` must be at least $\max(1, \text{nrhs})$.

ldb The leading dimension of `b`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by *getrs_scratchpad_size* function.

Output Parameters

b The buffer `b` is overwritten by the solution matrix X .

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info=-i`, the i -th parameter had an illegal value.

If `info=i`, the i -th diagonal element of U is zero, and the solve could not be completed.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

getrs (USM Version)

Syntax

```

namespace oneapi::mkl::lapack {
    cl::sycl::event getsrs(cl::sycl::queue &queue, oneapi::mkl::transpose trans, std::int64_t
    ↪ n, std::int64_t nrhs, T *a, std::int64_t lda, std::int64_t *ipiv, T *b, std::int64_t
    ↪ ldb, T *scratchpad, std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &
    ↪ events = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

trans Indicates the form of the equations:

If `trans=oneapi::mkl::transpose::nontrans`, then $AX = B$ is solved for X .

If `trans=oneapi::mkl::transpose::trans`, then $A^T X = B$ is solved for X .

If `trans=oneapi::mkl::transpose::conjtrans`, then $A^H X = B$ is solved for X .

n The order of the matrix A and the number of rows in matrix B ($0 \leq n$).

nrhs The number of right-hand sides ($0 \leq nrhs$).

a Pointer to array containing the factorization of the matrix A , as returned by *getrf*. The second dimension of **a** must be at least $\max(1, n)$.

lda The leading dimension of **a**.

ipiv Array, size at least $\max(1, n)$. The **ipiv** array, as returned by *getrf*.

b The array **b** contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of **b** must be at least $\max(1, nrhs)$.

ldb The leading dimension of **b**.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type **T**. Size should not be less than the value returned by *gets_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

b The array **b** is overwritten by the solution matrix X .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the i -th parameter had an illegal value.

If `info=i`, the i -th diagonal element of U is zero, and the solve could not be completed.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

getrs_scratchpad_size

Computes size of scratchpad memory required for *getrs* function.

Description

`getrs_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *getrs* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

getrs_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t getrs_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::transpose_
↳trans, std::int64_t n, std::int64_t nrhs, std::int64_t lda, std::int64_t ldb)
}

```

Input Parameters

queue Device queue where calculations by *getrs* function will be performed.

trans Indicates the form of the equations:

If `trans=oneapi::mkl::transpose::nontrans`, then $AX = B$ is solved for X .

If `trans=oneapi::mkl::transpose::trans`, then $A^T X = B$ is solved for X .

If `trans=oneapi::mkl::transpose::conjtrans`, then $A^H X = B$ is solved for X .

n The order of the matrix A ($0 \leq n$) and the number of rows in matrix B ($0 \leq n$).

nrhs The number of right-hand sides ($0 \leq nrhs$).

lda The leading dimension of a.

ldb The leading dimension of b.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *getrs* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

hetrf

Computes the Bunch-Kaufman factorization of a complex Hermitian matrix.

Description

hetrf supports the following precisions.

T
std::complex<float>
std::complex<double>

The routine computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

- if `upper_lower=uplo::upper`, $A = UDU^H$
- if `upper_lower=uplo::lower`, $A = LDL^H$

where A is the input matrix, U and L are products of permutation and triangular matrices with unit diagonal (upper triangular for U and lower triangular for L), and D is a Hermitian block-diagonal matrix with 1×1 and 2×2 diagonal blocks. U and L have 2×2 unit diagonal blocks corresponding to the 2×2 blocks of D .

hetrf (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void hetrf(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<int_64,1> &ipiv,
    ↪ cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If `upper_lower=uplo::upper`, the buffer `a` stores the upper triangular part of the matrix A , and A is factored as UDU^H .

If `upper_lower=uplo::lower`, the buffer `a` stores the lower triangular part of the matrix A , and A is factored as LDL^H .

n The order of matrix A ($0 \leq n$).

a The buffer `a`, size $\max(1, \text{lda} \cdot n)$. The buffer `a` contains either the upper or the lower triangular part of the matrix A (see `upper_lower`). The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`.

scratchpad Buffer holding scratchpad memory to be used by the routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `hetrf_scratchpad_size` function.

Output Parameters

a The upper or lower triangular part of a is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

ipiv Buffer, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $\text{ipiv}(i) = k > 0$, then d_{ii} is a 1×1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If `upper_lower=oneapi::mkl::uplo::upper` and $\text{ipiv}(i) = \text{ipiv}(i - 1) = -m < 0$, then D has a 2×2 block in rows/columns i and $i-1$, and $(i - 1)$ -th row and column of A was interchanged with the m -th row and column.

If `upper_lower=oneapi::mkl::uplo::lower` and $\text{ipiv}(i) = \text{ipiv}(i + 1) = -m < 0$, then D has a 2×2 block in rows/columns i and $i + 1$, and $(i + 1)$ -th row and column of A was interchanged with the m -th row and column.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

hetrf (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event hetrf(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
↳std::int64_t n, T *a, std::int64_t lda, int_64 *ipiv, T *scratchpad, std::int64_t
↳scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If **upper_lower=uplo::upper**, the array a stores the upper triangular part of the matrix A , and A is factored as UDU^H .

If **upper_lower=uplo::lower**, the array a stores the lower triangular part of the matrix A , and A is factored as LDL^H .

n The order of matrix A ($0 \leq n$).

a The pointer to A , size $\max(1, \text{lda} \cdot n)$, containing either the upper or the lower triangular part of the matrix A (see **upper_lower**). The second dimension of a must be at least $\max(1, n)$.

lda The leading dimension of a .

scratchpad Pointer to scratchpad memory to be used by the routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by *hetrf_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a The upper or lower triangular part of a is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

ipiv Pointer to array of size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $\text{ipiv}(i) = k > 0$, then d_{ii} is a 1×1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If **upper_lower=oneapi::mkl::uplo::upper** and $\text{ipiv}(i) = \text{ipiv}(i - 1) = -m < 0$, then D has a 2×2 block in rows/columns i and $i - 1$, and $(i - 1)$ -th row and column of A was interchanged with the m -th row and column.

If **upper_lower=oneapi::mkl::uplo::lower** and $\text{ipiv}(i) = \text{ipiv}(i + 1) = -m < 0$, then D has a 2×2 block in rows/columns i and $i + 1$, and $(i + 1)$ -th row and column of A was interchanged with the m -th row and column.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

hetrf_scratchpad_size

Computes size of scratchpad memory required for `hetrf` function.

Description

`hetrf_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to `hetrf` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

hetrf_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t hetrf_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
    ↪lower, std::int64_t n, std::int64_t lda)
}
```

Input Parameters

queue Device queue where calculations by `hetrf` function will be performed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If `upper_lower=uplo::upper`, the buffer `a` stores the upper triangular part of the matrix A , and A is factored as UDU^H .

If `upper_lower=uplo::lower`, the buffer `a` stores the lower triangular part of the matrix A , and A is factored as LDL^H .

n The order of the matrix A ($0 \leq n$).

lda The leading dimension of *a*.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type *T* the scratchpad memory to be passed to *hetrf* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

orgqr

Generates the real orthogonal matrix *Q* of the QR factorization formed by *geqrf*.

Description

orgqr supports the following precisions.

T
float
double

The routine generates the whole or part of $m \times m$ orthogonal matrix *Q* of the QR factorization formed by the routine *geqrf*.

Usually *Q* is determined from the QR factorization of an *m* by *p* matrix *A* with $m \geq p$. To compute the whole matrix *Q*, use:

```
oneapi::mkl::lapack::orgqr(queue, m, m, p, a, lda, tau, scratchpad, scratchpad_size)
```

To compute the leading *p* columns of *Q* (which form an orthonormal basis in the space spanned by the columns of *A*):

```
oneapi::mkl::lapack::orgqr(queue, m, p, p, a, lda, tau, scratchpad, scratchpad_size)
```

To compute the matrix Q^k of the QR factorization of leading *k* columns of the matrix *A*:

```
oneapi::mkl::lapack::orgqr(queue, m, m, k, a, lda, tau, scratchpad, scratchpad_size)
```

To compute the leading *k* columns of Q^k (which form an orthonormal basis in the space spanned by leading *k* columns of the matrix *A*):

```
oneapi::mkl::lapack::orgqr(queue, m, k, k, a, lda, tau, scratchpad, scratchpad_size)
```

orgqr (Buffer Version)

Syntax

```

namespace oneapi::mkl::lapack {
    void orgqr(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, std::int64_t k,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &tau,
    ↪ cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n \leq m$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a The buffer a as returned by *geqrf*.

lda The leading dimension of a ($lda \leq m$).

tau The buffer τ as returned by *geqrf*.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by *orgqr_scratchpad_size* function.

Output Parameters

a Overwritten by n leading columns of the $m \times m$ orthogonal matrix Q .

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The *info* code of the problem can be obtained by *info()* method of exception object:

If $info = -i$, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

orgqr (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event orgqr(cl::sycl::queue &queue, std::int64_t m, std::int64_t n,
↳std::int64_t k, T *a, std::int64_t lda, T *tau, T *scratchpad, std::int64_t scratchpad_
↳size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n \leq m$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a The pointer to a as returned by `geqrf`.

lda The leading dimension of a ($lda \leq m$).

tau The pointer to τ as returned by `geqrf`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `orgqr_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by n leading columns of the $m \times m$ orthogonal matrix Q .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

orgqr_scratchpad_size

Computes size of scratchpad memory required for *orgqr* function.

Description

`orgqr_scratchpad_size` supports the following precisions.

T
float
double

Computes the number of elements of type T the scratchpad memory to be passed to *orgqr* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

orgqr_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t orgqr_scratchpad_size(cl::sycl::queue &queue, std::int64_t m, std::int64_t
        ↪ n, std::int64_t k, std::int64_t lda)
    }
}
```

Input Parameters

queue Device queue where calculations by *orgqr* function will be performed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n \leq m$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

lda The leading dimension of a .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to `orgqr` function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

ormqr

Multiplies a real matrix by the orthogonal matrix Q of the QR factorization formed by `geqrf`.

Description

ormqr supports the following precisions.

T
float
double

The routine multiplies a rectangular real $m \times n$ matrix C by Q or Q^T , where Q is the complex unitary matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)^T H(2)^T \dots H(k)^T$ as returned by the RQ factorization routine `gerqf`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products QC , $Q^T C$, CQ , or CQ^T (overwriting the result over C).

ormqr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void ormqr(cl::sycl::queue &queue, oneapi::mkl::side side, oneapi::mkl::transpose_
↳ trans, std::int64_t m, std::int64_t n, std::int64_t k, cl::sycl::buffer<T,1> &a,
↳ std::int64_t lda, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &c, std::int64_t_
↳ ldc, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

side If `side = oneapi::mkl::side::left`, Q or Q^T is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^T is applied to C from the right.

trans If `trans = oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans = oneapi::mkl::transpose::trans`, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q

If `side = oneapi::mkl::side::left`, $0 \leq k \leq m$

If `side = oneapi::mkl::side::right`, $0 \leq k \leq n$

a The buffer `a` as returned by *geqrf*. The second dimension of `a` must be at least $\max(1, k)$.

lda The leading dimension of `a`.

tau The buffer `tau` as returned by *geqrf*.

c The buffer `c` contains the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by the *ormqr_scratchpad_size* function.

Output Parameters

c Overwritten by the product QC , Q^TC , CQ , or CQ^T (as specified by `side` and `trans`).

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

ormqr (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event ormqr(cl::sycl::queue &queue, oneapi::mkl::side side,
    ↪ oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, std::int64_t k, T *a,
    ↪ std::int64_t lda, T *tau, T *c, std::int64_t ldc, T *scratchpad, std::int64_t
    ↪ scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

side If `side = oneapi::mkl::side::left`, Q or Q^T is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^T is applied to C from the right.

trans If `trans = oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans = oneapi::mkl::transpose::trans`, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q

If `side = oneapi::mkl::side::left`, $0 \leq k \leq m$

If `side = oneapi::mkl::side::right`, $0 \leq k \leq n$

a The pointer to `a` as returned by `geqrf`. The second dimension of `a` must be at least $\max(1, k)$.

lda The leading dimension of `a`.

tau The pointer to `tau` as returned by `geqrf`.

c The pointer `c` points to the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by the `ormqr_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

c Overwritten by the product QC , $Q^T C$, CQ , or CQ^T (as specified by `side` and `trans`).

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the *i*-th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

ormqr_scratchpad_size

Computes size of scratchpad memory required for *ormqr* function.

Description

`ormqr_scratchpad_size` supports the following precisions.

T
float
double

Computes the number of elements of type T the scratchpad memory to be passed to *ormqr* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

ormqr_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t ormqr_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::side side,
        ↪ oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, std::int64_t k,
        ↪ std::int64_t lda, std::int64_t ldc, std::int64_t &scratchpad_size)
    }

```

Input Parameters

queue Device queue where calculations by *ormqr* function will be performed.

side If side=oneapi::mkl::side::left, Q or Q^T is applied to C from the left.

If side=oneapi::mkl::side::right, Q or Q^T is applied to C from the right.

trans If trans=oneapi::mkl::transpose::nontrans, the routine multiplies C by Q .

If trans=oneapi::mkl::transpose::trans, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n \leq m$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

lda The leading dimension of a.

ldc The leading dimension of c.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *ormqr* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

ormrq

Multiplies a real matrix by the orthogonal matrix Q of the RQ factorization formed by *gerqf*.

Description

`ormrq` supports the following precisions.

T
float
double

The routine multiplies a rectangular real $m \times n$ matrix C by Q or Q^T , where Q is the complex unitary matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)^T H(2)^T \dots H(k)^T$ as returned by the RQ factorization routine *gerqf*.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products QC , $Q^T C$, CQ , or CQ^T (overwriting the result over C).

ormrq (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void ormrq(cl::sycl::queue &queue, oneapi::mkl::side side, oneapi::mkl::transpose_
    ↪ trans, std::int64_t m, std::int64_t n, std::int64_t k, cl::sycl::buffer<T,1> &a,
    ↪ std::int64_t lda, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &c, std::int64_t_
    ↪ ldc, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

side If `side = oneapi::mkl::side::left`, Q or Q^T is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^T is applied to C from the right.

trans If `trans = oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans = oneapi::mkl::transpose::trans`, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q

If `side = oneapi::mkl::side::left`, $0 \leq k \leq m$

If `side = oneapi::mkl::side::right`, $0 \leq k \leq n$

a The buffer `a` as returned by *gerqf*. The second dimension of `a` must be at least $\max(1, k)$.

lda The leading dimension of `a`.

tau The buffer `tau` as returned by *gerqf*.

c The buffer `c` contains the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the *ormrq_scratchpad_size* function.

Output Parameters

c Overwritten by the product QC , $Q^T C$, CQ , or CQ^T (as specified by *side* and *trans*).

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The *info* code of the problem can be obtained by *info()* method of exception object:

If *info* = $-i$, the *i*-th parameter had an illegal value.

If *info* equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

ormrq (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event ormrq(cl::sycl::queue &queue, oneapi::mkl::side side,
    ↪ oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, std::int64_t k, T *a,
    ↪ std::int64_t lda, T *tau, T *c, std::int64_t ldc, T *scratchpad, std::int64_t
    ↪ scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

side If `side = oneapi::mkl::side::left`, Q or Q^T is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^T is applied to C from the right.

trans If `trans = oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans = oneapi::mkl::transpose::trans`, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q

If `side = oneapi::mkl::side::left`, $0 \leq k \leq m$

If `side = oneapi::mkl::side::right`, $0 \leq k \leq n$

a The pointer to `a` as returned by *gerqf*. The second dimension of `a` must be at least $\max(1, k)$.

lda The leading dimension of `a`.

tau The pointer to `tau` as returned by *gerqf*.

c The pointer `c` points to the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by the *ormrq_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

c Overwritten by the product QC , $Q^T C$, CQ , or CQ^T (as specified by `side` and `trans`).

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

ormrq_scratchpad_size

Computes size of scratchpad memory required for `ormrq` function.

Description

`ormrq_scratchpad_size` supports the following precisions.

T
float
double

Computes the number of elements of type T the scratchpad memory to be passed to `ormrq` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

ormrq_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t ormrq_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::side side,
        ↪ oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, std::int64_t k,
        ↪ std::int64_t lda, std::int64_t ldc);
}
```

Input Parameters

queue Device queue where calculations by the `ormrq` function will be performed.

side If `side = oneapi::mkl::side::left`, Q or Q^T is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^T is applied to C from the right.

trans If `trans=oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans=oneapi::mkl::transpose::trans`, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n \leq m$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

lda The leading dimension of a.

ldc The leading dimension of c.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *ormrq* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix.

Description

potrf supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A :

$A = U^T U$ for real data, $A = U^H U$ for complex data	if <code>upper_lower=oneapi::mkl::uplo::upper</code>
$A = LL^T$ for real data, $A = LL^H$ for complex data	if <code>upper_lower=oneapi::mkl::uplo::lower</code>

where L is a lower triangular matrix and U is upper triangular.

potrf (Buffer Version)

Syntax

```

namespace oneapi::mkl::lapack {
    void potrf(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &scratchpad,
    ↪ std::int64_t scratchpad_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If `upper_lower=oneapi::mkl::uplo::upper`, the array `a` stores the upper triangular part of the matrix A , and the strictly lower triangular part of the matrix is not referenced.

If `upper_lower=oneapi::mkl::uplo::lower`, the array `a` stores the lower triangular part of the matrix A , and the strictly upper triangular part of the matrix is not referenced.

n Specifies the order of the matrix A ($0 \leq n$).

a Buffer holding input matrix A . The buffer `a` contains either the upper or the lower triangular part of the matrix A (see `upper_lower`). The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `potrf_scratchpad_size` function.

Output Parameters

a The buffer `a` is overwritten by the Cholesky factor U or L , as specified by `upper_lower`.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If $\text{info} = i$, and $\text{detail}()$ returns 0, then the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

If info equals to value passed as scratchpad size, and $\text{detail}()$ returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by $\text{detail}()$ method of exception object.

potrf (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event potrf(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
    ↪ std::int64_t n, T *a, std::int64_t lda, T *scratchpad, std::int64_t scratchpad_size,
    ↪ const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If $\text{upper_lower}=\text{oneapi::mkl::uplo::upper}$, the array a stores the upper triangular part of the matrix A , and the strictly lower triangular part of the matrix is not referenced.

If $\text{upper_lower}=\text{oneapi::mkl::uplo::lower}$, the array a stores the lower triangular part of the matrix A , and the strictly upper triangular part of the matrix is not referenced.

n Specifies the order of the matrix A ($0 \leq n$).

a Pointer to input matrix A . The array a contains either the upper or the lower triangular part of the matrix A (see upper_lower). The second dimension of a must be at least $\max(1, n)$.

lda The leading dimension of a .

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by $\text{potrf_scratchpad_size}$ function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a The memory pointer to by pointer a is overwritten by the Cholesky factor U or L , as specified by upper_lower .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, and `detail()` returns 0, then the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

potrf_scratchpad_size

Computes size of scratchpad memory required for *potrf* function.

Description

`potrf_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *potrf* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

potrf_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t potrf_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
↳lower, std::int64_t n, std::int64_t lda)
}

```

Input Parameters

queue Device queue where calculations by *potrf* function will be performed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If `upper_lower = oneapi::mkl::uplo::upper`, the array `a` stores the upper triangular part of the matrix A , and the strictly lower triangular part of the matrix is not referenced.

If `upper_lower = oneapi::mkl::uplo::lower`, the array `a` stores the lower triangular part of the matrix A , and the strictly upper triangular part of the matrix is not referenced.

n Specifies the order of the matrix A ($0 \leq n$).

lda The leading dimension of `a`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type `T` the scratchpad memory to be passed to *potrf* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

potri

Computes the inverse of a symmetric (Hermitian) positive-definite matrix using the Cholesky factorization.

Description

`potri` supports the following precisions.

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

The routine computes the inverse A^{-1} of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A . Before calling this routine, call `potrf` to factorize A .

potri (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void potri(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &scratchpad,
    ↪ std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates how the input matrix A has been factored:

If `upper_lower = oneapi::mkl::uplo::upper`, the upper triangle of A is stored.

If `upper_lower = oneapi::mkl::uplo::lower`, the lower triangle of A is stored.

n Specifies the order of the matrix A ($0 \leq n$).

a Contains the factorization of the matrix A , as returned by `potrf`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `potri_scratchpad_size` function.

Output Parameters

a Overwritten by the upper or lower triangle of the inverse of A . Specified by `upper_lower`.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, the i -th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

If `info` equals to value passed as `scratchpad_size`, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

potri (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event potri(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
    ↪ std::int64_t n, T *a, std::int64_t lda, T *scratchpad, std::int64_t scratchpad_size,
    ↪ const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates how the input matrix A has been factored:

If `upper_lower = oneapi::mkl::uplo::upper`, the upper triangle of A is stored.

If `upper_lower = oneapi::mkl::uplo::lower`, the lower triangle of A is stored.

n Specifies the order of the matrix A ($0 \leq n$).

a Contains the factorization of the matrix A , as returned by `potrf`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `potri_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by the upper or lower triangle of the inverse of A . Specified by `upper_lower`.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, the i -th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: [LAPACK Linear Equation Routines](#)

potri_scratchpad_size

Computes size of scratchpad memory required for `potri` function.

Description

`potri_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to `potri` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

potri_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t potri_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
↳lower, std::int64_t n, std::int64_t lda)
}
```

Input Parameters

queue Device queue where calculations by *potri* function will be performed.

upper_lower Indicates how the input matrix *A* has been factored:

If `upper_lower = oneapi::mkl::uplo::upper`, the upper triangle of *A* is stored.

If `upper_lower = oneapi::mkl::uplo::lower`, the lower triangle of *A* is stored.

n Specifies the order of the matrix *A* ($0 \leq n$).

lda The leading dimension of *a*.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type *T* the scratchpad memory to be passed to *potri* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

potrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite coefficient matrix.

Description

potrs supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine solves for X the system of linear equations $AX = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$A = U^T U$ for real data, $A = U^H U$ for complex data	if upper_lower=oneapi::mkl::uplo::upper
$A = LL^T$ for real data, $A = LL^H$ for complex data	if upper_lower=oneapi::mkl::uplo::lower

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call *potrf* to compute the Cholesky factorization of A .

potrs (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void potrs(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ std::int64_t nrhs, cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &
    ↪ b, std::int64_t ldb, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates how the input matrix has been factored:

If upper_lower = oneapi::mkl::uplo::upper, the upper triangle U of A is stored, where $A = U^T$ for real data, $A = U^H U$ for complex data.

If upper_lower = oneapi::mkl::uplo::lower, the lower triangle L of A is stored, where $A = LL^T$ for real data, $A = LL^H$ for complex data.

n The order of matrix A ($0 \leq n$).

nrhs The number of right-hand sides ($0 \leq nrhs$).

a Buffer containing the factorization of the matrix A , as returned by *potrf*. The second dimension of **a** must be at least $\max(1, n)$.

lda The leading dimension of **a**.

b The array **b** contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of **b** must be at least $\max(1, nrhs)$.

ldb The leading dimension of **b**.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type **T**. Size should not be less than the value returned by *potrs_scratchpad_size* function.

Output Parameters

b Overwritten by the solution matrix *X*.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the *i*-th parameter had an illegal value.

If `info = i`, the *i*-th diagonal element of the Cholesky factor is zero, and the solve could not be completed.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

potrs (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event potrs(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
    ↪ std::int64_t n, std::int64_t nrhs, T *a, std::int64_t lda, T *b, std::int64_t ldb, T
    ↪ *scratchpad, std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events,
    ↪ = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates how the input matrix has been factored:

If `upper_lower = oneapi::mkl::uplo::upper`, the upper triangle U of A is stored, where $A = U^T U$ for real data, $A = U^H U$ for complex data.

If `upper_lower = oneapi::mkl::uplo::lower`, the lower triangle L of A is stored, where $A = L L^T$ for real data, $A = L L^H$ for complex data.

n The order of matrix A ($0 \leq n$).

nrhs The number of right-hand sides ($0 \leq nrhs$).

a Pointer to array containing the factorization of the matrix A , as returned by *potrf*. The second dimension of **a** must be at least $\max(1, n)$.

lda The leading dimension of **a**.

b The array **b** contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of **b** must be at least $\max(1, nrhs)$.

ldb The leading dimension of **b**.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by *potrs_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

b Overwritten by the solution matrix X .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, the i -th diagonal element of the Cholesky factor is zero, and the solve could not be completed.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

potrs_scratchpad_size

Computes size of scratchpad memory required for *potrs* function.

Description

`potrs_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *potrs* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

potrs_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t potrs_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
    ↪lower, std::int64_t n, std::int64_t nrhs, std::int64_t lda, std::int64_t ldb)
}
```

Input Parameters

queue Device queue where calculations by *potrs* function will be performed.

upper_lower Indicates how the input matrix has been factored:

If `upper_lower = oneapi::mkl::uplo::upper`, the upper triangle U of A is stored, where $A = U^T U$ for real data, $A = U^H U$ for complex data.

If `upper_lower = oneapi::mkl::uplo::lower`, the lower triangle L of A is stored, where $A = LL^T$ for real data, $A = LL^H$ for complex data.

n The order of matrix A ($0 \leq n$).

nrhs The number of right-hand sides ($0 \leq nrhs$).

lda The leading dimension of a.

ldb The leading dimension of b.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *potrs* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

sytrf

Computes the Bunch-Kaufman factorization of a symmetric matrix.

Description

sytrf supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine computes the factorization of a real/complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

- if `upper_lower=uplo::upper`, $A = UDU^T$
- if `upper_lower=uplo::lower`, $A = LDL^T$

where A is the input matrix, U and L are products of permutation and triangular matrices with unit diagonal (upper triangular for U and lower triangular for L), and D is a symmetric block-diagonal matrix with 1×1 and 2×2 diagonal blocks. U and L have 2×2 unit diagonal blocks corresponding to the 2×2 blocks of D .

sytrf (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void sytrf(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<int_64,1> &ipiv,
    ↪ cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If `upper_lower=uplo::upper`, the buffer `a` stores the upper triangular part of the matrix A , and A is factored as UDU^T .

If `upper_lower=uplo::lower`, the buffer `a` stores the lower triangular part of the matrix A , and A is factored as LDL^T .

n The order of matrix A ($0 \leq n$).

a The buffer `a`, size $\max(1, lda \cdot n)$. The buffer `a` contains either the upper or the lower triangular part of the matrix A (see `upper_lower`). The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `sytrf_scratchpad_size` function.

Output Parameters

a The upper or lower triangular part of `a` is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

ipiv Buffer, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If `ipiv(i) = k > 0`, then d_{ii} is a 1×1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If `upper_lower=oneapi::mkl::uplo::upper` and `ipiv(i) = ipiv(i - 1) = -m < 0`, then D has a 2×2 block in rows/columns i and $i-1$, and $(i - 1)$ -th row and column of A was interchanged with the m -th row and column.

If `upper_lower=oneapi::mkl::uplo::lower` and `ipiv(i) = ipiv(i + 1) = -m < 0`, then D has a 2×2 block in rows/columns i and $i + 1$, and $(i + 1)$ -th row and column of A was interchanged with the m -th row and column.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If $\text{info} = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

sytrf (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event sytrf(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
    ↪ std::int64_t n, T *a, std::int64_t lda, int_64 *ipiv, T *scratchpad, std::int64_t
    ↪ scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If `upper_lower=uplo::upper`, the array `a` stores the upper triangular part of the matrix A , and A is factored as UDU^T .

If `upper_lower=uplo::lower`, the array `a` stores the lower triangular part of the matrix A , and A is factored as LDL^T .

n The order of matrix A ($0 \leq n$).

a The pointer to A , size $\max(1, \text{lda} \cdot n)$, containing either the upper or the lower triangular part of the matrix A (see `upper_lower`). The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `sytrf_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a The upper or lower triangular part of `a` is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

ipiv Pointer to array of size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $\text{ipiv}(i) = k > 0$, then d_{ii} is a 1×1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If `upper_lower=oneapi::mkl::uplo::upper` and $\text{ipiv}(i) = \text{ipiv}(i - 1) = -m < 0$, then D has a 2×2 block in rows/columns i and $i - 1$, and $(i - 1)$ -th row and column of A was interchanged with the m -th row and column.

If `upper_lower=oneapi::mkl::uplo::lower` and $\text{ipiv}(i) = \text{ipiv}(i + 1) = -m < 0$, then D has a 2×2 block in rows/columns i and $i + 1$, and $(i + 1)$ -th row and column of A was interchanged with the m -th row and column.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

sytrf_scratchpad_size

Computes size of scratchpad memory required for *sytrf* function.

Description

`sytrf_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *sytrf* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

sytrf_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t sytrf_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
↳lower, std::int64_t n, std::int64_t lda)
}

```

Input Parameters

queue Device queue where calculations by *sytrf* function will be performed.

upper_lower Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If `upper_lower=uplo::upper`, the buffer `a` stores the upper triangular part of the matrix A , and A is factored as UDU^T .

If `upper_lower=uplo::lower`, the buffer `a` stores the lower triangular part of the matrix A , and A is factored as LDL^T .

n The order of the matrix A ($0 \leq n$).

lda The leading dimension of `a`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type `T` the scratchpad memory to be passed to *sytrf* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

trtrs

Solves a system of linear equations with a triangular coefficient matrix, with multiple right-hand sides.

Description

trtrs supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine solves for X the following systems of linear equations with a triangular matrix A , with multiple right-hand sides stored in B :

$AX = B$	if transa = transpose::nontrans,
$A^T X = B$	if transa = transpose::trans,
$A^H X = B$	if transa = transpose::conjtrans (for complex matrices only).

trtrs (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void trtrs(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
    ↪ oneapi::mkl::transpose transa, oneapi::mkl::diag unit_diag, std::int64_t n, std::int64_t
    ↪ nrhs, cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &b,
    ↪ std::int64_t ldb, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates whether A is upper or lower triangular:

If upper_lower = uplo::upper, then A is upper triangular.

If upper_lower = uplo::lower, then A is lower triangular.

transa If transa = transpose::nontrans, then $AX = B$ is solved for X .

If transa = transpose::trans, then $A^T X = B$ is solved for X .

If transa = transpose::conjtrans, then $A^H X = B$ is solved for X .

unit_diag If unit_diag = diag::nonunit, then A is not a unit triangular matrix.

If unit_diag = diag::unit, then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array a .

n The order of A ; the number of rows in B ; $n \geq 0$.

nrhs The number of right-hand sides; $nrhs \geq 0$.

a Buffer containing the matrix A . The second dimension of a must be at least $\max(1, n)$.

lda The leading dimension of a ; $lda \geq \max(1, n)$.

b Buffer containing the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of **b** at least $\max(1, \text{nrhs})$.

ldb The leading dimension of **b**; $\text{ldb} \geq \max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `trtrs_scratchpad_size` function.

Output Parameters

b Overwritten by the solution matrix X .

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

trtrs (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event trtrs(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
        ↪ oneapi::mkl::transpose transa, oneapi::mkl::diag unit_diag, std::int64_t n, std::int64_t
        ↪ nrhs, T *a, std::int64_t lda, T *b, std::int64_t ldb, T *scratchpad, std::int64_t
        ↪ scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Indicates whether A is upper or lower triangular:

If `upper_lower = uplo::upper`, then A is upper triangular.

If `upper_lower = uplo::lower`, then A is lower triangular.

transa If `transa = transpose::nontrans`, then $AX = B$ is solved for X .

If `transa = transpose::trans`, then $A^T X = B$ is solved for X .

If `transa = transpose::conjtrans`, then $A^H X = B$ is solved for X .

unit_diag If `unit_diag = diag::nonunit`, then A is not a unit triangular matrix.

If `unit_diag = diag::unit`, then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array `a`.

n The order of A ; the number of rows in B ; $n \geq 0$.

nrhs The number of right-hand sides; $\text{nrhs} \geq 0$.

a Array containing the matrix A . The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`; $\text{lda} \geq \max(1, n)$.

b Array containing the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of `b` at least $\max(1, \text{nrhs})$.

ldb The leading dimension of `b`; $\text{ldb} \geq \max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `trtrs_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

b Overwritten by the solution matrix X .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If $\text{info} = -i$, the i -th parameter had an illegal value.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

trtrs_scratchpad_size

Computes size of scratchpad memory required for `trtrs` function.

Description

`trtrs_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to `trtrs` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

trtrs_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t trtrs_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
        ↪lower, oneapi::mkl::transpose trans, oneapi::mkl::diag diag, std::int64_t n,
        ↪std::int64_t nrhs, std::int64_t lda, std::int64_t ldb)
    }
}
```

Input Parameters

queue Device queue where calculations by `trtrs` function will be performed.

upper_lower Indicates whether A is upper or lower triangular:

If `upper_lower = uplo::upper`, then A is upper triangular.

If `upper_lower = uplo::lower`, then A is lower triangular.

trans Indicates the form of the equations:

If `trans=oneapi::mkl::transpose::nontrans`, then $AX = B$ is solved for X .

If `trans=oneapi::mkl::transpose::trans`, then $A^T X = B$ is solved for X .

If `trans=oneapi::mkl::transpose::conjtrans`, then $A^H X = B$ is solved for X .

diag If `diag = oneapi::mkl::diag::nonunit`, then A is not a unit triangular matrix.

If `unit_diag = diag::unit`, then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array `a`.

n The order of A ; the number of rows in B ; $n \geq 0$.

nrhs The number of right-hand sides ($0 \leq \text{nrhs}$).

lda The leading dimension of `a`; `lda` $\geq \max(1, n)$.

ldb The leading dimension of `b`; `ldb` $\geq \max(1, n)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Return Value

The number of elements of type `T` the scratchpad memory to be passed to `trtrs` function should be able to hold.

Parent topic: [LAPACK Linear Equation Routines](#)

ungqr

Generates the complex unitary matrix Q of the QR factorization formed by `geqrf`.

Description

`ungqr` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

The routine generates the whole or part of $m \times m$ unitary matrix Q of the QR factorization formed by the routines `geqrf`.

Usually Q is determined from the QR factorization of an $m \times p$ matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
oneapi::mkl::lapack::ungqr(queue, m, m, p, a, lda, tau, scratchpad, scratchpad_size)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
oneapi::mkl::lapack::ungqr(queue, m, p, p, a, lda, tau, scratchpad, scratchpad_size)
```

To compute the matrix Q^k of the QR factorization of the leading k columns of the matrix A :

```
oneapi::mkl::lapack::ungqr(queue, m, m, k, a, lda, tau, scratchpad, scratchpad_size)
```

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by the leading k columns of the matrix A):

```
oneapi::mkl::lapack::ungqr(queue, m, k, k, a, lda, tau, scratchpad, scratchpad_size)
```

ungqr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void ungqr(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, std::int64_t k,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &tau,
    ↪ cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a The buffer a as returned by *geqrf*.

lda The leading dimension of a ($lda \leq m$).

tau The buffer τ as returned by *geqrf*.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by *ungqr_scratchpad_size* function.

Output Parameters

a Overwritten by n leading columns of the $m \times m$ orthogonal matrix Q .

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

ungqr (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event ungqr(cl::sycl::queue &queue, std::int64_t m, std::int64_t n,
↳ std::int64_t k, T *a, std::int64_t lda, T *tau, T *scratchpad, std::int64_t scratchpad_
↳ size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a The pointer to a as returned by `geqrf`.

lda The leading dimension of a ($lda \leq m$).

tau The pointer to τ as returned by `geqrf`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `ungqr_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by n leading columns of the $m \times m$ orthogonal matrix Q .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

ungqr_scratchpad_size

Computes size of scratchpad memory required for *ungqr* function.

Description

`ungqr_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to *ungqr* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

ungqr_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t ungqr_scratchpad_size(cl::sycl::queue &queue, std::int64_t m, std::int64_t
        ↪ n, std::int64_t k, std::int64_t lda)
    }

```

Input Parameters

queue Device queue where calculations by *ungqr* function will be performed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns the matrix A ($0 \leq n \leq m$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

lda The leading dimension of a .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *ungqr* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

unmqr

Multiplies a complex matrix by the unitary matrix Q of the QR factorization formed by *geqrf*.

Description

`unmqr` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

The routine multiplies a rectangular complex $m \times n$ matrix C by Q or Q^H , where Q is the complex unitary matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)^H H(2)^H \dots H(k)^H$ as returned by the RQ factorization routine *gerqf*.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products QC , $Q^H C$, CQ , or CQ^H (overwriting the result over C).

unmqr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void unmqr(cl::sycl::queue &queue, oneapi::mkl::side side, oneapi::mkl::transpose_
    ↪ trans, std::int64_t m, std::int64_t n, std::int64_t k, cl::sycl::buffer<T,1> &a,
    ↪ std::int64_t lda, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &c, std::int64_t_
    ↪ ldc, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

side If `side = oneapi::mkl::side::left`, Q or Q^H is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^H is applied to C from the right.

trans If `trans = oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans = oneapi::mkl::transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q

If `side = oneapi::mkl::side::left`, $0 \leq k \leq m$

If `side = oneapi::mkl::side::right`, $0 \leq k \leq n$

a The buffer `a` as returned by *gerqf*. The second dimension of `a` must be at least $\max(1, k)$.

lda The leading dimension of `a`.

tau The buffer `tau` as returned by *gerqf*.

c The buffer `c` contains the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the `unmqr_scratchpad_size` function.

Output Parameters

c Overwritten by the product QC , $Q^H C$, CQ , or CQ^H (as specified by `side` and `trans`).

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

unmqr (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event unmqr(cl::sycl::queue &queue, oneapi::mkl::side side,
        ↪ oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, std::int64_t k, T *a,
        ↪ std::int64_t lda, T *tau, T *c, std::int64_t ldc, T *scratchpad, std::int64_t
        ↪ scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

side If `side = oneapi::mkl::side::left`, Q or Q^H is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^H is applied to C from the right.

trans If `trans = oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans = oneapi::mkl::transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q

If `side = oneapi::mkl::side::left`, $0 \leq k \leq m$

If `side = oneapi::mkl::side::right`, $0 \leq k \leq n$

a The pointer to `a` as returned by *geqrf*. The second dimension of `a` must be at least $\max(1, k)$.

lda The leading dimension of `a`.

tau The pointer to `tau` as returned by *geqrf*.

c The pointer `c` points to the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by *unmqr_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

c Overwritten by the product QC , $Q^H C$, CQ , or CQ^H (as specified by `side` and `trans`).

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

unmqr_scratchpad_size

Computes size of scratchpad memory required for `unmqr` function.

Description

`unmqr_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to `unmqr` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

unmqr_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t unmqr_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::side side,
        ↪ oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, std::int64_t k,
        ↪ std::int64_t lda, std::int64_t ldc, std::int64_t &scratchpad_size)
}

```

Input Parameters

queue Device queue where calculations by `unmqr` function will be performed.

side If `side=oneapi::mkl::side::left`, Q or Q^H is applied to C from the left.

If `side=oneapi::mkl::side::right`, Q or Q^H is applied to C from the right.

trans If `trans=oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans=oneapi::mkl::transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns the matrix C ($0 \leq n \leq m$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

lda The leading dimension of a.

ldc The leading dimension of c.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *unmrq* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

unmrq

Multiplies a complex matrix by the unitary matrix Q of the RQ factorization formed by *gerqf*.

Description

unmrq supports the following precisions.

T
std::complex<float>
std::complex<double>

The routine multiplies a rectangular complex $m \times n$ matrix C by Q or Q^H , where Q is the complex unitary matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)^H H(2)^H \dots H(k)^H$ as returned by the RQ factorization routine *gerqf*.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products QC , $Q^H C$, CQ , or CQ^H (overwriting the result over C).

unmrq (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void unmrq(cl::sycl::queue &queue, oneapi::mkl::side side, oneapi::mkl::transpose_
    ↪ trans, std::int64_t m, std::int64_t n, std::int64_t k, cl::sycl::buffer<T,1> &a,
    ↪ std::int64_t lda, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &c, std::int64_t_
    ↪ ldc, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

side If `side = oneapi::mkl::side::left`, Q or Q^H is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^H is applied to C from the right.

trans If `trans = oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans = oneapi::mkl::transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q

If `side = oneapi::mkl::side::left`, $0 \leq k \leq m$

If `side = oneapi::mkl::side::right`, $0 \leq k \leq n$

a The buffer `a` as returned by *gerqf*. The second dimension of `a` must be at least $\max(1, k)$.

lda The leading dimension of `a`.

tau The buffer `tau` as returned by *gerqf*.

c The buffer `c` contains the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by *unmrq_scratchpad_size* function.

Output Parameters

c Overwritten by the product QC , $Q^H C$, CQ , or CQ^H (as specified by `side` and `trans`).

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

unmrq (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event unmrq(cl::sycl::queue &queue, oneapi::mkl::side side,
    ↪ oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, std::int64_t k, T *a,
    ↪ std::int64_t lda, T *tau, T *c, std::int64_t ldc, T *scratchpad, std::int64_t
    ↪ scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

side If `side = oneapi::mkl::side::left`, Q or Q^H is applied to C from the left.

If `side = oneapi::mkl::side::right`, Q or Q^H is applied to C from the right.

trans If `trans = oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans = oneapi::mkl::transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n$).

k The number of elementary reflectors whose product defines the matrix Q

If `side = oneapi::mkl::side::left`, $0 \leq k \leq m$

If `side = oneapi::mkl::side::right`, $0 \leq k \leq n$

a The pointer to `a` as returned by `gerqf`. The second dimension of `a` must be at least $\max(1, k)$.

lda The leading dimension of `a`.

tau The pointer to `tau` as returned by `gerqf`.

c The pointer `c` points to the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `unmrq_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

c Overwritten by the product QC , $Q^H C$, CQ , or CQ^H (as specified by `side` and `trans`).

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the *i*-th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Linear Equation Routines*

unmrq_scratchpad_size

Computes size of scratchpad memory required for *unmrq* function.

Description

`unmrq_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to *unmrq* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

unmrq_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t unmrq_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::side side,
        ↪ oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, std::int64_t k,
        ↪ std::int64_t lda, std::int64_t ldc)
}

```

Input Parameters

queue Device queue where calculations by the unmrq function will be performed.

side If `side = oneapi::mkl::side::left`, Q or Q^T is applied to C from the left. If `side = oneapi::mkl::side::right`, Q or Q^T is applied to C from the right.

trans If `trans=oneapi::mkl::transpose::nontrans`, the routine multiplies C by Q .

If `trans=oneapi::mkl::transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($0 \leq m$).

n The number of columns in the matrix C ($0 \leq n \leq m$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

lda The leading dimension of a .

ldc The leading dimension of c .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *unmrq* function should be able to hold.

Parent topic: *LAPACK Linear Equation Routines*

LAPACK Singular Value and Eigenvalue Problem Routines

LAPACK Singular Value and Eigenvalue Problem routines are used for singular value and eigenvalue problems, and for performing a number of related computational tasks. The following table lists the LAPACK Singular Value and Eigenvalue Problem routine groups.

Routines	Scratchpad Size Routines	Description
<i>gebrd</i>	<i>gebrd_scratchpad_size</i>	Reduces a general matrix to bidiagonal form.
<i>gesvd</i>	<i>gesvd_scratchpad_size</i>	Computes the singular value decomposition of a general rectangular matrix.
<i>heevd</i>	<i>heevd_scratchpad_size</i>	Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.
<i>hegvd</i>	<i>hegvd_scratchpad_size</i>	Computes all eigenvalues and, optionally, all eigenvectors of a complex generalized Hermitian definite eigenproblem using divide and conquer algorithm.
<i>hetrd</i>	<i>hetrd_scratchpad_size</i>	Reduces a complex Hermitian matrix to tridiagonal form.
<i>orgbr</i>	<i>orgbr_scratchpad_size</i>	Generates the real orthogonal matrix Q or P^T determined by <i>gebrd</i> .
<i>orgtr</i>	<i>orgtr_scratchpad_size</i>	Generates the real orthogonal matrix Q determined by <i>sytrd</i> .
<i>ormtr</i>	<i>ormtr_scratchpad_size</i>	Multiplies a real matrix by the orthogonal matrix Q determined by <i>sytrd</i> .
<i>syevd</i>	<i>syevd_scratchpad_size</i>	Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric matrix using divide and conquer algorithm.
<i>sygvd</i>	<i>sygvd_scratchpad_size</i>	Computes all eigenvalues and, optionally, all eigenvectors of a real generalized symmetric definite eigenproblem using divide and conquer algorithm.
<i>sytrd</i>	<i>sytrd_scratchpad_size</i>	Reduces a real symmetric matrix to tridiagonal form.
<i>ungbr</i>	<i>ungbr_scratchpad_size</i>	Generates the complex unitary matrix Q or P^T determined by <i>gebrd</i> .
<i>ungtr</i>	<i>ungtr_scratchpad_size</i>	Generates the complex unitary matrix Q determined by <i>hetrd</i> .
<i>unmtr</i>	<i>unmtr_scratchpad_size</i>	Multiplies a complex matrix by the unitary matrix Q determined by <i>hetrd</i> .

gebrd

Reduces a general matrix to bidiagonal form.

Description

gebrd supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

The routine reduces a general $m \times n$ matrix A to a bidiagonal matrix B by an orthogonal (unitary) transformation.

If $m \geq n$, the reduction is given by $A = QBP^H = \begin{pmatrix} B_1 \\ 0 \end{pmatrix} P^H = Q_1 B_1 P_1^H$

where B_1 is an $n \times n$ upper diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; Q_1 consists of the first n columns of Q .

If $m < n$, the reduction is given by

$$A = QBP^H = Q \begin{pmatrix} B_1 \\ 0 \end{pmatrix} P^H = Q_1 B_1 P_1^H,$$

where B_1 is an $m \times m$ lower diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; P_1 consists of the first m columns of P .

The routine does not form the matrices Q and P explicitly, but represents them as products of elementary reflectors. Routines are provided to work with the matrices Q and P in this representation:

If the matrix A is real,

- to compute Q and P explicitly, call *orgbr*.

If the matrix A is complex,

- to compute Q and P explicitly, call *ungbr*

gebrd (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void gebrd(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, cl::sycl::buffer<T,
    ↪1> &a, std::int64_t lda, cl::sycl::buffer<realT,1> &d, cl::sycl::buffer<realT,1> &e,
    ↪cl::sycl::buffer<T,1> &tauq, cl::sycl::buffer<T,1> &taup, cl::sycl::buffer<T,1> &
    ↪scratchpad, std::int64_t scratchpad_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

a The buffer a , size $(lda, *)$. The buffer a contains the matrix A . The second dimension of a must be at least $\max(1, m)$.

lda The leading dimension of a .

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by *gebrd_scratchpad_size* function.

Output Parameters

a If $m \geq n$, the diagonal and first super-diagonal of a are overwritten by the upper bidiagonal matrix B . The elements below the diagonal, with the buffer τ_{uq} , represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the buffer τ_{up} , represent the orthogonal matrix P as a product of elementary reflectors.

If $m < n$, the diagonal and first sub-diagonal of a are overwritten by the lower bidiagonal matrix B . The elements below the first subdiagonal, with the buffer τ_{uq} , represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the buffer τ_{up} , represent the orthogonal matrix P as a product of elementary reflectors.

d Buffer, size at least $\max(1, \min(m, n))$. Contains the diagonal elements of B .

e Buffer, size at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of B .

tauq Buffer, size at least $\max(1, \min(m, n))$. The scalar factors of the elementary reflectors which represent the orthogonal or unitary matrix Q .

taup Buffer, size at least $\max(1, \min(m, n))$. The scalar factors of the elementary reflectors which represent the orthogonal or unitary matrix P .

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the `i`-th parameter had an illegal value.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

gebrd (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event gebrd(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, T *a,
↳std::int64_t lda, RealT *d, RealT *e, T *tauq, T *taup, T *scratchpad, std::int64_t
↳scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

a Pointer to matrix A . The second dimension of `a` must be at least $\max(1, m)$.

lda The leading dimension of `a`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `gebrd_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a If $m \geq n$, the diagonal and first super-diagonal of a are overwritten by the upper bidiagonal matrix B . The elements below the diagonal, with the array `tauq`, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array `taup`, represent the orthogonal matrix P as a product of elementary reflectors.

If $m < n$, the diagonal and first sub-diagonal of a are overwritten by the lower bidiagonal matrix B . The elements below the first subdiagonal, with the array `tauq`, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array `taup`, represent the orthogonal matrix P as a product of elementary reflectors.

d Pointer to memory of size at least $\max(1, \min(m, n))$. Contains the diagonal elements of B .

e Pointer to memory of size at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of B .

tauq Pointer to memory of size at least $\max(1, \min(m, n))$. The scalar factors of the elementary reflectors which represent the orthogonal or unitary matrix Q .

taup Pointer to memory of size at least $\max(1, \min(m, n))$. The scalar factors of the elementary reflectors which represent the orthogonal or unitary matrix P .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

gebrd_scratchpad_size

Computes size of scratchpad memory required for *gebrd* function.

Description

`gebrd_scratchpad_size` supports the following precisions.

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to `gebrd` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t gebrd_scratchpad_size(cl::sycl::queue &queue, std::int64_t m, std::int64_t
    ↪ n, std::int64_t lda)
}
```

Input Parameters

queue Device queue where calculations by `gebrd` function will be performed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

lda The leading dimension of a .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *gesvd* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

gesvd

Computes the singular value decomposition of a general rectangular matrix.

Description

gesvd supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

gesvd (Buffer Version)

Description

The routine computes the singular value decomposition (SVD) of a real/complex $m \times n$ matrix A , optionally computing the left and/or right singular vectors. The SVD is written as

$$A = U\Sigma V^T \text{ for real routines}$$

$$A = U\Sigma V^H \text{ for complex routines}$$

where Σ is an $m \times n$ diagonal matrix, U is an $m \times m$ orthogonal/unitary matrix, and V is an $n \times n$ orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m, n)$ columns of U and V are the left and right singular vectors of A .

Syntax

```
namespace oneapi::mkl::lapack {
    void gesvd(cl::sycl::queue &queue, oneapi::mkl::job jobv, oneapi::mkl::job jobvt,
    ↪ std::int64_t m, std::int64_t n, cl::sycl::buffer<T,1> &a, std::int64_t lda,
    ↪ cl::sycl::buffer<realT,1> &s, cl::sycl::buffer<T,1> &u, std::int64_t ldu,
    ↪ cl::sycl::buffer<T,1> &vt, std::int64_t ldvt, cl::sycl::buffer<T,1> &scratchpad,
    ↪ std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

jobu Must be `job::allvec`, `job::somevec`, `job::overwritevec`, or `job::novec`. Specifies options for computing all or part of the matrix U .

If `jobu = job::allvec`, all m columns of U are returned in the buffer `u`;

if `jobu = job::somevec`, the first $\min(m, n)$ columns of U (the left singular vectors) are returned in the buffer `u`;

if `jobu = job::overwritevec`, the first $\min(m, n)$ columns of U (the left singular vectors) are overwritten on the buffer `a`;

if `jobu = job::novec`, no columns of U (no left singular vectors) are computed.

jobvt Must be `job::allvec`, `job::somevec`, `job::overwritevec`, or `job::novec`. Specifies options for computing all or part of the matrix V^T/V^H .

If `jobvt = job::allvec`, all n columns of V^T/V^H are returned in the buffer `vt`;

if `jobvt = job::somevec`, the first $\min(m, n)$ columns of V^T/V^H (the left singular vectors) are returned in the buffer `vt`;

if `jobvt = job::overwritevec`, the first $\min(m, n)$ columns of V^T/V^H (the left singular vectors) are overwritten on the buffer `a`;

if `jobvt = job::novec`, no columns of V^T/V^H (no left singular vectors) are computed.

`jobvt` and `jobu` cannot both be `job::overwritevec`.

m The number of rows in the matrix A ($0 \leq m$).

a The buffer `a`, size $(lda, *)$. The buffer `a` contains the matrix A . The second dimension of `a` must be at least $\max(1, m)$.

lda The leading dimension of `a`.

ldu The leading dimension of `u`.

ldvt The leading dimension of `vt`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `gesvd_scratchpad_size` function.

Output Parameters

a On exit,

If `jobu = job::overwritevec`, `a` is overwritten with the first $\min(m, n)$ columns of U (the left singular vectors stored columnwise);

If `jobvt = job::overwritevec`, `a` is overwritten with the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored rowwise);

If `jobu` \neq `job::overwritevec` and `jobvt` \neq `job::overwritevec`, the contents of `a` are destroyed.

s Buffer containing the singular values, size at least $\max(1, \min(m, n))$. Contains the singular values of A sorted so that $s(i) \geq s(i + 1)$.

u Buffer containing U ; the second dimension of `u` must be at least $\max(1, m)$ if `jobu = job::allvec`, and at least $\max(1, \min(m, n))$ if `jobu = job::somevec`.

If `jobu = job::allvec`, `u` contains the $m \times m$ orthogonal/unitary matrix U .

If `jobu = job::somevec`, `u` contains the first $\min(m, n)$ columns of U (the left singular vectors stored column-wise).

If `jobu = job::novec` or `job::overwritevec`, `u` is not referenced.

vt Buffer containing V^T ; the second dimension of `vt` must be at least $\max(1, n)$.

If `jobvt = job::allvec`, `vt` contains the $n \times n$ orthogonal/unitary matrix V^T/V^H .

If `jobvt = job::somevec`, `vt` contains the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored row-wise).

If `jobvt = job::novec` or `job::overwritevec`, `vt` is not referenced.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the i -th parameter had an illegal value.

If `info=i`, then if `bdsqr` did not converge, i specifies how many superdiagonals of the intermediate bidiagonal form B did not converge to zero, and `scratchpad(2:min(m,n))` contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in `s` (not necessarily sorted). B satisfies $A = UBVT^T$, so it has the same singular values as A , and singular vectors related by U and V^T .

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

gesvd (USM Version)

Description

The routine computes the singular value decomposition (SVD) of a real/complex $m \times n$ matrix A , optionally computing the left and/or right singular vectors. The SVD is written as

$A = U\Sigma V^T$ for real routines

$A = U\Sigma V^H$ for complex routines

where Σ is an $m \times n$ diagonal matrix, U is an $m \times m$ orthogonal/unitary matrix, and V is an $n \times n$ orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m, n)$ columns of U and V are the left and right singular vectors of A .

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event gesvd(cl::sycl::queue &queue, oneapi::mkl::job jobu, oneapi::mkl::job_
    ↪ jobvt, std::int64_t m, std::int64_t n, T *a, std::int64_t lda, RealT *s, T *u,
    ↪ std::int64_t ldu, T *vt, std::int64_t ldvt, T *scratchpad, std::int64_t scratchpad_
    ↪ size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

jobu Must be `job::allvec`, `job::somevec`, `job::overwritevec`, or `job::novec`. Specifies options for computing all or part of the matrix U .

If `jobu = job::allvec`, all m columns of U are returned in the array `u`;

if `jobu = job::somevec`, the first $\min(m, n)$ columns of U (the left singular vectors) are returned in the array `u`;

if `jobu = job::overwritevec`, the first $\min(m, n)$ columns of U (the left singular vectors) are overwritten on the array `u`;

if `jobu = job::novec`, no columns of U (no left singular vectors) are computed.

jobvt Must be `job::allvec`, `job::somevec`, `job::overwritevec`, or `job::novec`. Specifies options for computing all or part of the matrix V^T/V^H .

If `jobvt = job::allvec`, all n columns of V^T/V^H are returned in the array `vt`;

if `jobvt = job::somevec`, the first $\min(m, n)$ columns of V^T/V^H (the left singular vectors) are returned in the array `vt`;

if `jobvt = job::overwritevec`, the first $\min(m, n)$ columns of V^T/V^H (the left singular vectors) are overwritten on the array `vt`;

if `jobvt = job::novec`, no columns of V^T/V^H (no left singular vectors) are computed.

`jobvt` and `jobu` cannot both be `job::overwritevec`.

m The number of rows in the matrix A ($0 \leq m$).

a Pointer to array `a`, size `(lda, *)`, containing the matrix A . The second dimension of `a` must be at least $\max(1, m)$.

lda The leading dimension of `a`.

ldu The leading dimension of `u`.

ldvt The leading dimension of `vt`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `gesvd_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a On exit,

If `jobu = job::overwritevec`, `a` is overwritten with the first $\min(m, n)$ columns of U (the left singular vectors stored columnwise);

If `jobvt = job::overwritevec`, `a` is overwritten with the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored rowwise);

If `jobu` \neq `job::overwritevec` and `jobvt` \neq `job::overwritevec`, the contents of `a` are destroyed.

s Array containing the singular values, size at least $\max(1, \min(m, n))$. Contains the singular values of A sorted so that $s(i) \geq s(i + 1)$.

u Array containing U ; the second dimension of `u` must be at least $\max(1, m)$ if `jobu = job::allvec`, and at least $\max(1, \min(m, n))$ if `jobu = job::somevec`.

If `jobu = job::allvec`, `u` contains the $m \times m$ orthogonal/unitary matrix U .

If `jobu = job::somevec`, `u` contains the first $\min(m, n)$ columns of U (the left singular vectors stored columnwise).

If `jobu = job::novec` or `job::overwritevec`, `u` is not referenced.

vt Array containing V^T ; the second dimension of `vt` must be at least $\max(1, n)$.

If `jobvt = job::allvec`, `vt` contains the $n \times n$ orthogonal/unitary matrix V^T/V^H .

If `jobvt = job::somevec`, `vt` contains the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored row-wise).

If `jobvt = job::novec` or `job::overwritevec`, `vt` is not referenced.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the i -th parameter had an illegal value.

If `info=i`, then if `bdsqr` did not converge, i specifies how many superdiagonals of the intermediate bidiagonal form B did not converge to zero, and `scratchpad(2:min(m,n))` contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in `s` (not necessarily sorted). B satisfies $A = UBV^T$, so it has the same singular values as A , and singular vectors related by U and V^T .

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

gesvd_scratchpad_size

Computes size of scratchpad memory required for `gesvd` function.

Description

`gesvd_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to `gesvd` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

gesvd_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t gesvd_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::job jobu,
    ↪ oneapi::mkl::job jobvt, std::int64_t m, std::int64_t n, std::int64_t lda, std::int64_t_
    ↪ ldu, std::int64_t ldvt)
}
```

Input Parameters

queue Device queue where calculations by `gesvd` function will be performed.

jobu Must be `job::allvec`, `job::somevec`, `job::overwritevec`, or `job::novect`. Specifies options for computing all or part of the matrix U .

If `jobu = job::allvec`, all m columns of U are returned in the buffer `u`;

if `jobu = job::somevec`, the first $\min(m, n)$ columns of U (the left singular vectors) are returned in the buffer `v`;

if `jobu = job::overwritevec`, the first $\min(m, n)$ columns of U (the left singular vectors) are overwritten on the buffer `a`;

if `jobu = job::novec`, no columns of U (no left singular vectors) are computed.

jobvt Must be `job::allvec`, `job::somevec`, `job::overwritevec`, or `job::novec`. Specifies options for computing all or part of the matrix V^T/V^H .

If `jobvt = job::allvec`, all n columns of V^T/V^H are returned in the buffer `vt`;

if `jobvt = job::somevec`, the first $\min(m, n)$ columns of V^T/V^H (the left singular vectors) are returned in the buffer `vt`;

if `jobvt = job::overwritevec`, the first $\min(m, n)$ columns of V^T/V^H (the left singular vectors) are overwritten on the buffer `a`;

if `jobvt = job::novec`, no columns of V^T/V^H (no left singular vectors) are computed.

m The number of rows in the matrix A ($0 \leq m$).

n The number of columns in the matrix A ($0 \leq n$).

lda The leading dimension of `a`.

ldu The leading dimension of `u`.

ldvt The leading dimension of `vt`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type `T` the scratchpad memory to be passed to *gesvd* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

heevd

Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.

Description

heevd supports the following precisions.

T
std::complex<float>
std::complex<double>

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A . In other words, it can compute the spectral factorization of A as: $A = Z\Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$Az_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

heevd (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void heevd(cl::sycl::queue &queue, oneapi::mkl::job jobz, oneapi::mkl::uplo upper_
    ↪lower, std::int64_t n, butter<T,1> &a, std::int64_t lda, cl::sycl::buffer<realT,1> &w,
    ↪cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

jobz Must be `job::novec` or `job::vec`.

If `jobz = job::novec`, then only eigenvalues are computed.

If `jobz = job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = job::upper`, a stores the upper triangular part of A .

If `upper_lower = job::lower`, a stores the lower triangular part of A .

n The order of the matrix A ($0 \leq n$).

a The buffer `a`, size `(lda, *)`. The buffer `a` contains the matrix A . The second dimension of `a` must be at least `max(1, n)`.

lda The leading dimension of `a`. Must be at least `max(1, n)`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `heevd_scratchpad_size` function.

Output Parameters

- a** If `jobz = job::vec`, then on exit this buffer is overwritten by the unitary matrix Z which contains the eigenvectors of A .
- w** Buffer, size at least n . Contains the eigenvalues of the matrix A in ascending order.
- scratchpad** Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the i -th parameter had an illegal value.

If `info=i`, and `jobz = oneapi::mkl::job::novec`, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If `info=i`, and `jobz = oneapi::mkl::job::vec`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n + 1)$ through $mod(info, n + 1)$.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

heevd (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event heevd(cl::sycl::queue &queue, oneapi::mkl::job jobz, oneapi::mkl::uplo_
    ↪ upper_lower, std::int64_t n, butter<T,1> &a, std::int64_t lda, RealT *w, T *scratchpad,
    ↪ std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

jobz Must be `job::novec` or `job::vec`.

If `jobz = job::novec`, then only eigenvalues are computed.

If `jobz = job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = job::upper`, a stores the upper triangular part of A .

If `upper_lower = job::lower`, a stores the lower triangular part of A .

n The order of the matrix A ($0 \leq n$).

a Pointer to array containing A , size $(lda, *)$. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`. Must be at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `heevd_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a If `jobz = job::vec`, then on exit this array is overwritten by the unitary matrix Z which contains the eigenvectors of A .

w Pointer to array of size at least n . Contains the eigenvalues of the matrix A in ascending order.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info=-i`, the i -th parameter had an illegal value.

If `info=i`, and `jobz = oneapi::mkl::job::novec`, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If `info=i`, and `jobz = oneapi::mkl::job::vec`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns `info/(n + 1)` through `mod(info, n + 1)`.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

heevd_scratchpad_size

Computes size of scratchpad memory required for *heevd* function.

Description

`heevd_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to *heevd* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

heevd_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t heevd_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::job jobz,
        ↪oneapi::mkl::uplo upper_lower, std::int64_t n, std::int64_t lda)
}

```

Input Parameters

queue Device queue where calculations by *heevd* function will be performed.

jobz Must be `job::novec` or `job::vec`.

If `jobz = job::novec`, then only eigenvalues are computed.

If `jobz = job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = job::upper`, a stores the upper triangular part of *A*.

If `upper_lower = job::lower`, a stores the lower triangular part of *A*.

n The order of the matrix *A* ($0 \leq n$).

lda The leading dimension of *a*.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *heevd* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

hegvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem using a divide and conquer method.

Description

hegvd supports the following precisions.

T
std::complex<float>
std::complex<double>

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$Ax = \lambda Bx, ABx = \lambda x, \text{ or } BAx = \lambda x.$$

Here A and B are assumed to be Hermitian and B is also positive definite.

It uses a divide and conquer algorithm.

hegvd (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void hegvd(cl::sycl::queue &queue, std::int64_t itype, oneapi::mkl::job jobz,
    ↪ oneapi::mkl::uplo upper_lower, std::int64_t n, cl::sycl::buffer<T,1> &a, std::int64_t_
    ↪ lda, cl::sycl::buffer<T,1> &b, std::int64_t ldb, cl::sycl::buffer<realT,1> &w,
    ↪ cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

itype Must be 1 or 2 or 3. Specifies the problem type to be solved:

if `itype = 1`, the problem type is $Ax = \lambda Bx$;

if `itype = 2`, the problem type is $ABx = \lambda x$;

if `itype = 3`, the problem type is $BAx = \lambda x$.

jobz Must be `jobz::novec` or `jobz::vec`.

If `jobz = jobz::novec`, then only eigenvalues are computed.

If `jobz = jobz::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, `a` and `b` store the upper triangular part of A and B .

If `upper_lower = uplo::lower`, `a` and `b` stores the lower triangular part of A and B .

n The order of the matrices A and B ($0 \leq n$).

a Buffer, size `a(lda,*)` contains the upper or lower triangle of the Hermitian matrix A , as specified by `upper_lower`.

The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`; at least $\max(1, n)$.

b Buffer, size `b(ldb,*)` contains the upper or lower triangle of the Hermitian matrix B , as specified by `upper_lower`.

The second dimension of `b` must be at least $\max(1, n)$.

ldb The leading dimension of `b`; at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `hegvd_scratchpad_size` function.

Output Parameters

a On exit, if `jobz = jobz::vec`, then if `info = 0`, `a` contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:

if `itype = 1` or `itype = 2`, $Z^H B Z = I$;

if `itype = 3`, $Z^H B^{-1} Z = I$;

If `jobz = jobz::novec`, then on exit the upper triangle (if `upper_lower = uplo::upper`) or the lower triangle (if `upper_lower = uplo::lower`) of A , including the diagonal, is destroyed.

b On exit, if `info ≤ n`, the part of `b` containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^H U$ or $B = L L^H$.

w Buffer, size at least n . If `info = 0`, contains the eigenvalues of the matrix A in ascending order.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

For `info ≤ n`:

If `info = i`, and `jobz = oneapi::mkl::job::novec`, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero;

If `info = i`, and `jobz = oneapi::mkl::job::vec`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $\text{info}/(n + 1)$ through $\text{mod}(\text{info}, n + 1)$.

For `info > n`:

If `info = n + i`, for $1 ≤ i ≤ n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

hegvd (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event hegvd(cl::sycl::queue &queue, std::int64_t itype, oneapi::mkl::job_
↪ jobz, oneapi::mkl::uplo upper_lower, std::int64_t n, T *a, std::int64_t lda, T *b,
↪ std::int64_t ldb, RealT *w, T *scratchpad, std::int64_t scratchpad_size, const_
↪ std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

itype Must be 1 or 2 or 3. Specifies the problem type to be solved:

if `itype = 1`, the problem type is $Ax = \lambda Bx$;

if `itype = 2`, the problem type is $ABx = \lambda x$;

if `itype = 3`, the problem type is $BAx = \lambda x$.

jobz Must be `jobz::novec` or `jobz::vec`.

If `jobz = jobz::novec`, then only eigenvalues are computed.

If `jobz = jobz::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, `a` and `b` store the upper triangular part of A and B .

If `upper_lower = uplo::lower`, `a` and `b` stores the lower triangular part of A and B .

n The order of the matrices A and B ($0 \leq n$).

a Pointer to array of size `a(lda, *)` containing the upper or lower triangle of the Hermitian matrix A , as specified by `upper_lower`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`; at least $\max(1, n)$.

b Pointer to array of size `b(l db, *)` containing the upper or lower triangle of the Hermitian matrix B , as specified by `upper_lower`. The second dimension of `b` must be at least $\max(1, n)$.

ldb The leading dimension of `b`; at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `hegvd_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a On exit, if `jobz = jobz::vec`, then if `info = 0`, `a` contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:

if `itype = 1` or `itype = 2`, $Z^H B Z = I$;

if `itype = 3`, $Z^H B^{-1} Z = I$;

If `jobz = jobz::novec`, then on exit the upper triangle (if `upper_lower = uplo::upper`) or the lower triangle (if `upper_lower = uplo::lower`) of A , including the diagonal, is destroyed.

b On exit, if `info ≤ n`, the part of `b` containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^H U$ or $B = LL^H$.

w Pointer to array of size at least `n`. If `info = 0`, contains the eigenvalues of the matrix A in ascending order.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

For `info ≤ n`:

If `info = i`, and `jobz = oneapi::mkl::job::novec`, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero;

If `info = i`, and `jobz = oneapi::mkl::job::vec`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns `info/(n + 1)` through `mod(info, n + 1)`.

For `info > n`:

If `info = n + i`, for $1 ≤ i ≤ n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

If `info` equals to value passed as `scratchpad_size`, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

hegvd_scratchpad_size

Computes size of `scratchpad` memory required for *hegvd* function.

Description

`hegvd_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to `hegvd` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

hegvd_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t hegvd_scratchpad_size(cl::sycl::queue &queue, std::int64_t itype,
        ↪ oneapi::mkl::job jobz, oneapi::mkl::uplo upper_lower, std::int64_t n, std::int64_t lda,
        ↪ std::int64_t ldb)
}
```

Input Parameters

queue Device queue where calculations by `hegvd` function will be performed.

itype Must be 1 or 2 or 3. Specifies the problem type to be solved:

if `itype = 1`, the problem type is $Ax = \lambda Bx$;

if `itype = 2`, the problem type is $ABx = \lambda x$;

if `itype = 3`, the problem type is $B Ax = \lambda x$.

jobz Must be `job::novec` or `job::vec`.

If `jobz = job::novec`, then only eigenvalues are computed.

If `jobz = job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, a and b store the upper triangular part of A and B .

If `upper_lower = uplo::lower`, a and b store the lower triangular part of A and B .

n The order of the matrices A and B ($0 \leq n$).

lda The leading dimension of a. Currently `lda` is not referenced in this function.

ldb The leading dimension of b. Currently `ldb` is not referenced in this function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *hegvd* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

hetrd

Reduces a complex Hermitian matrix to tridiagonal form.

Description

hetrd supports the following precisions.

Routine name	T
<i>chetrd</i>	<code>std::complex<float></code>
<i>zhetrd</i>	<code>std::complex<double></code>

The routine reduces a complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = QTQ^H$. The unitary matrix Q is not formed explicitly but is represented as a product of $n - 1$ elementary reflectors. Routines are provided to work with Q in this representation.

hetrd (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void hetrd(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<realT,1> &d,
    ↪ cl::sycl::buffer<realT,1> &e, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &
    ↪ scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, `a` stores the upper triangular part of A .

If `upper_lower = uplo::lower`, `a` stores the lower triangular part of A .

n The order of the matrices A ($0 \leq n$).

a Buffer, size $(lda, *)$. The buffer `a` contains either the upper or lower triangle of the Hermitian matrix A , as specified by `upper_lower`.

The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`; at least $\max(1, n)$

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `hetrd_scratchpad_size` function.

Output Parameters

a On exit,

if `upper_lower = uplo::upper`, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the buffer `tau`, represent the orthogonal matrix Q as a product of elementary reflectors;

if `upper_lower = uplo::lower`, the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the buffer `tau`, represent the orthogonal matrix Q as a product of elementary reflectors.

d Buffer containing the diagonal elements of the matrix T . The dimension of `d` must be at least $\max(1, n)$.

e Buffer containing the off diagonal elements of the matrix T . The dimension of `e` must be at least $\max(1, n - 1)$.

tau Buffer, size at least $\max(1, n - 1)$. Stores $(n - 1)$ scalars that define elementary reflectors in decomposition of the unitary matrix Q in a product of $n - 1$ elementary reflectors.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If $\text{info} = -i$, the i -th parameter had an illegal value.

If info equals to value passed as `scratchpad_size`, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

hetrd (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event hetrd(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
↳std::int64_t n, T *a, std::int64_t lda, RealT *d, RealT *e, T *tau, T *scratchpad,
↳std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, `a` stores the upper triangular part of A .

If `upper_lower = uplo::lower`, `a` stores the lower triangular part of A .

n The order of the matrices A ($0 \leq n$).

a The pointer to matrix A , size $(\text{lda}, *)$. Contains either the upper or lower triangle of the Hermitian matrix A , as specified by `upper_lower`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`; at least $\max(1, n)$

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `hetrd_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a On exit,

if `upper_lower = uplo::upper`, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array `tau`, represent the orthogonal matrix Q as a product of elementary reflectors;

if `upper_lower = uplo::lower`, the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array `tau`, represent the orthogonal matrix Q as a product of elementary reflectors.

d Pointer to diagonal elements of the matrix T . The dimension of `d` must be at least $\max(1, n)$.

e Pointer to off diagonal elements of the matrix T . The dimension of `e` must be at least $\max(1, n - 1)$.

tau Pointer to array of size at least $\max(1, n - 1)$. Stores $(n - 1)$ scalars that define elementary reflectors in decomposition of the unitary matrix Q in a product of $n - 1$ elementary reflectors.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

hetrd_scratchpad_size

Computes size of scratchpad memory required for *hetrd* function.

Description

`hetrd_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to *hetrd* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

hetrd_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t hetrd_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
↳lower, std::int64_t n, std::int64_t lda)
}

```

Input Parameters

queue Device queue where calculations by *hetrd* function will be performed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, a stores the upper triangular part of *A* and *B*.

If `upper_lower = uplo::lower`, a stores the lower triangular part of *A*.

n The order of the matrices *A* and *B* ($0 \leq n$).

lda The leading dimension of *a*. Currently, *lda* is not referenced in this function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type *T* the scratchpad memory to be passed to *hetrd* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

orgbr

Generates the real orthogonal matrix *Q* or P^T determined by *gebrd*.

orgbr supports the following precisions.

T
float
double

Description

The routine generates the whole or part of the orthogonal matrices Q and P^T formed by the routines *gebrd*. All valid combinations of arguments are described in *Input parameters*. In most cases you need the following:

To compute the whole $m \times m$ matrix Q :

```
orgbr(queue, generate::q, m, m, n, a, ...)
```

(note that the array *a* must have at least m columns).

To form the n leading columns of Q if $m > n$:

```
orgbr(queue, generate::q, m, n, n, a, ...)
```

To compute the whole $n \times n$ matrix P^T :

```
orgbr(queue, generate::p, n, n, m, a, ...)
```

(note that the array *a* must have at least n rows).

To form the m leading rows of P^T if $m < n$:

```
orgbr(queue, generate::p, m, n, m, a, ...)
```

orgbr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void orgbr(cl::sycl::queue &queue, oneapi::mkl::generate gen, std::int64_t m,
    ↪ std::int64_t n, std::int64_t k, cl::sycl::buffer<T,1> &a, std::int64_t lda,
    ↪ cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_
    ↪ size)
}
```

Input Parameters

queue The queue where the routine should be executed.

gen Must be `generate::q` or `generate::p`.

If `gen = generate::q`, the routine generates the matrix Q .

If `gen = generate::p`, the routine generates the matrix P^T .

m The number of rows in the matrix Q or P^T to be returned ($0 \leq m$).

If `gen = generate::q`, $m \leq n \leq \min(m, k)$.

If `gen = generate::p`, $n \leq m \leq \min(n, k)$.

n The number of rows in the matrix Q or P^T to be returned ($0 \leq n$). See *m* for constraints.

k If `gen = generate::q`, the number of columns in the original $m \times k$ matrix reduced by *gebrd*.

If `gen = generate::p`, the number of rows in the original $k \times n$ matrix reduced by *gebrd*.

a The buffer *a* as returned by *gebrd*.

lda The leading dimension of *a*.

tau Buffer, size $\min(m, k)$ if *gen* = *generate::q*, size $\min(n, k)$ if *gen* = *generate::p*. Scalar factor of the elementary reflectors, as returned by *gebrd* in the array *tauq* or *taup*.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type *T*. Size should not be less than the value returned by *orgbr_scratchpad_size* function.

Output Parameters

a Overwritten by *n* leading columns of the $m \times m$ orthogonal matrix *Q* or P^T (or the leading rows or columns thereof) as specified by *gen*, *m*, and *n*.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The *info* code of the problem can be obtained by *info()* method of exception object:

If *info* = $-i$, the *i*-th parameter had an illegal value.

If *info* equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

orgbr (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event orgbr(cl::sycl::queue &queue, oneapi::mkl::generate gen, std::int64_t
    ↪m, std::int64_t n, std::int64_t k, T *a, std::int64_t lda, T *tau, T *scratchpad,
    ↪std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

gen Must be `generate::q` or `generate::p`.

If `gen = generate::q`, the routine generates the matrix Q .

If `gen = generate::p`, the routine generates the matrix P^T .

m The number of rows in the matrix Q or P^T to be returned ($0 \leq m$).

If `gen = generate::q`, $m \leq n \leq \min(m, k)$.

If `gen = generate::p`, $n \leq m \leq \min(n, k)$.

n The number of rows in the matrix Q or P^T to be returned ($0 \leq n$). See `m` for constraints.

k If `gen = generate::q`, the number of columns in the original $m \times k$ matrix reduced by *gebrd*.

If `gen = generate::p`, the number of rows in the original $k \times n$ matrix reduced by *gebrd*.

a Pointer to array `a` as returned by *gebrd*.

lda The leading dimension of `a`.

tau Pointer to array of size $\min(m, k)$ if `gen = generate::q`, size $\min(n, k)$ if `gen = generate::p`. Scalar factor of the elementary reflectors, as returned by *gebrd* in the array `tauq` or `taup`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by *orgbr_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by `n` leading columns of the $m \times m$ orthogonal matrix Q or P^T (or the leading rows or columns thereof) as specified by `gen`, `m`, and `n`.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

orgbr_scratchpad_size

Computes size of scratchpad memory required for `orgbr` function.

`orgbr_scratchpad_size` supports the following precisions.

T
float
double

Description

Computes the number of elements of type T the scratchpad memory to be passed to `orgbr` function should be able to hold. Calls to this routine must specify the template parameter explicitly.

orgbr_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
  template <typename T>
  std::int64_t orgbr_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::generate gen,
  ↪ std::int64_t m, std::int64_t n, std::int64_t k, std::int64_t lda, std::int64_t &
  ↪ scratchpad_size)
}
```

Input Parameters

queue Device queue where calculations by `orgbr` function will be performed.

gen Must be `generate::q` or `generate::p`.

If `gen = generate::q`, the routine generates the matrix Q .

If `gen = generate::p`, the routine generates the matrix P^T .

m The number of rows in the matrix Q or P^T to be returned ($0 \leq m$).

If `gen = generate::q`, $m \leq n \leq \min(m, k)$.

If `gen = generate::p`, $n \leq m \leq \min(n, k)$.

n The number of rows in the matrix Q or P^T to be returned ($0 \leq n$). See `m` for constraints.

k If `gen = generate::q`, the number of columns in the original $m \times k$ matrix returned by *gebrd*.

If `gen = generate::p`, the number of rows in the original $k \times n$ matrix returned by *gebrd*.

lda The leading dimension of *a*.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type *T* the scratchpad memory to be passed to *orgbr* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

orgtr

Generates the real orthogonal matrix *Q* determined by *sytrd*.

Description

orgtr supports the following precisions.

T
float
double

The routine explicitly generates the $n \times n$ orthogonal matrix *Q* formed by *sytrd* when reducing a real symmetric matrix *A* to tridiagonal form: $A = QTQ^T$. Use this routine after a call to *sytrd*.

orgtr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void orgtr(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &tau,
    ↪ cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Must be `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to `sytrd`.

n The order of the matrix Q ($0 \leq n$).

a The buffer `a` as returned by `sytrd`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a` ($n \leq lda$).

tau The buffer `tau` as returned by `sytrd`. The dimension of `tau` must be at least $\max(1, n - 1)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `orgtr_scratchpad_size` function.

Output Parameters

a Overwritten by the orthogonal matrix Q .

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

orgtr (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event orgtr(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
        ↪ std::int64_t n, T *a, std::int64_t lda, T *tau, T *scratchpad, std::int64_t scratchpad_
        ↪ size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Must be `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to `sytrd`.

n The order of the matrix Q ($0 \leq n$).

a The pointer to `a` as returned by `sytrd`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a` ($n \leq lda$).

tau The pointer to `tau` as returned by `sytrd`. The dimension of `tau` must be at least $\max(1, n - 1)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `orgtr_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by the orthogonal matrix Q .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

orgtr_scratchpad_size

Computes size of scratchpad memory required for *orgtr* function.

Description

orgtr_scratchpad_size supports the following precisions.

T
float
double

Computes the number of elements of type T the scratchpad memory to be passed to *orgtr* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

orgtr_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t orgtr_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
    ↪lower, std::int64_t n, std::int64_t lda)
}
```

Input Parameters

queue Device queue where calculations by *orgtr* function will be performed.

upper_lower Must be `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to *sytrd*.

n The order of the matrix Q ($0 \leq n$).

lda The leading dimension of a ($n \leq lda$).

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *ormtr* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

ormtr

Multiplies a real matrix by the real orthogonal matrix Q determined by *sytrd*.

Description

ormtr supports the following precisions.

T
float
double

The routine multiplies a real matrix C by Q or Q^T , where Q is the orthogonal matrix Q formed by:ref:oneapi::mkl::lapack::sytrd when reducing a real symmetric matrix A to tridiagonal form: $A = QTQ^T$. Use this routine after a call to *sytrd*.

Depending on the parameters side and trans, the routine can form one of the matrix products QC , Q^TC , CQ , or CQ^T (overwriting the result on C).

ormtr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void ormtr(cl::sycl::queue &queue, oneapi::mkl::side side, oneapi::mkl::uplo upper_
    ↪lower, oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, cl::sycl::buffer
    ↪<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &c,
    ↪std::int64_t ldc, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

In the descriptions below, r denotes the order of Q :

$r = m$	if side = side::left
$r = n$	if side = side::right

queue The queue where the routine should be executed.

side Must be either side::left or side::right.

If side = side::left, Q or Q^T is applied to C from the left.

If side = side::right, Q or Q^T is applied to C from the right.

upper_lower Must be either uplo::upper or uplo::lower. Uses the same upper_lower as supplied to *sytrd*.

trans Must be either `transpose::nontrans` or `transpose::trans`.

If `trans = transpose::nontrans`, the routine multiplies C by Q .

If `trans = transpose::trans`, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($m \geq 0$).

n The number of columns in the matrix C ($n \geq 0$).

a The buffer `a` as returned by `sytrd`.

lda The leading dimension of `a` ($\max(1, r) \leq \text{lda}$).

tau The buffer `tau` as returned by `sytrd`. The dimension of `tau` must be at least $\max(1, r - 1)$.

c The buffer `c` contains the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c` ($\max(1, n) \leq \text{ldc}$).

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `ormtr_scratchpad_size` function.

Output Parameters

c Overwritten by the product QC , $Q^T C$, CC , or CC^T (as specified by `side` and `trans`).

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as `scratchpad_size`, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

ormtr (USM Version)

Syntax

```

namespace oneapi::mkl::lapack {
    cl::sycl::event ormtr(cl::sycl::queue &queue, oneapi::mkl::side side,
        ↪ oneapi::mkl::uplo upper_lower, oneapi::mkl::transpose trans, std::int64_t m,
        ↪ std::int64_t n, T *a, std::int64_t lda, T *tau, T *c, std::int64_t ldc, T *scratchpad,
        ↪ std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}

```

Input Parameters

In the descriptions below, r denotes the order of Q :

$r = m$	if <code>side = side::left</code>
$r = n$	if <code>side = side::right</code>

queue The queue where the routine should be executed.

side Must be either `side::left` or `side::right`.

If `side = side::left`, Q or Q^T is applied to C from the left.

If `side = side::right`, Q or Q^T is applied to C from the right.

upper_lower Must be either `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to *sytrd*.

trans Must be either `transpose::nontrans` or `transpose::trans`.

If `trans = transpose::nontrans`, the routine multiplies C by Q .

If `trans = transpose::trans`, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($m \geq 0$).

n The number of columns in the matrix C ($n \geq 0$).

a The pointer to a as returned by *sytrd*.

lda The leading dimension of a ($\max(1, r) \leq lda$).

tau The buffer `tau` as returned by *sytrd*. The dimension of `tau` must be at least $\max(1, r - 1)$.

c The pointer to memory containing the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c` ($\max(1, n) \leq ldc$).

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by *ormtr_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

c Overwritten by the product QC , $Q^T C$, CQ , or CQ^T (as specified by `side` and `trans`).

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the *i*-th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

ormtr_scratchpad_size

Computes size of scratchpad memory required for *ormtr* function.

Description

`ormtr_scratchpad_size` supports the following precisions.

T
float
double

Computes the number of elements of type T the scratchpad memory to be passed to *ormtr* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

ormtr_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t ormtr_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::side side,
        ↪ oneapi::mkl::uplo upper_lower, oneapi::mkl::transpose trans, std::int64_t m,
        ↪ std::int64_t n, std::int64_t lda, std::int64_t ldc)
    }

```

Input Parameters

In the descriptions below, r denotes the order of Q :

$r = m$	if side = side::left
$r = n$	if side = side::right

queue Device queue where calculations by *ormtr* function will be performed.

side Must be either side::left or side::right.

If side = side::left, Q or Q^T is applied to C from the left.

If side = side::right, Q or Q^T is applied to C from the right.

upper_lower Must be either uplo::upper or uplo::lower. Uses the same upper_lower as supplied to *sytrd*.

trans Must be either transpose::nontrans or transpose::trans.

If trans = transpose::nontrans, the routine multiplies C by Q .

If trans = transpose::trans, the routine multiplies C by Q^T .

m The number of rows in the matrix C ($m \geq 0$).

n The number of rows in the matrix C ($n \geq 0$).

lda The leading dimension of a ($\max(1, r) \leq lda$).

ldc The leading dimension of c ($\max(1, n) \leq ldc$).

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *ormtr* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

syevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric matrix using divide and conquer algorithm.

Description

syevd supports the following precisions.

T
float
double

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A . In other words, it can compute the spectral factorization of A as: $A = Z\Lambda Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$Az_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

syevd (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void syevd(cl::sycl::queue &queue, jobz jobz, oneapi::mkl::uplo upper_lower,
    ↪ std::int64_t n, cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &w,
    ↪ cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}

```

Input Parameters

queue The queue where the routine should be executed.

jobz Must be `job::novec` or `job::vec`.

If `jobz = job::novec`, then only eigenvalues are computed.

If `jobz = job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = job::upper`, a stores the upper triangular part of A .

If `upper_lower = job::lower`, a stores the lower triangular part of A .

n The order of the matrix A ($0 \leq n$).

a The buffer **a**, size $(lda, *)$. The buffer **a** contains the matrix A . The second dimension of **a** must be at least $\max(1, n)$.

lda The leading dimension of **a**. Must be at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by *syevd_scratchpad_size* function.

Output Parameters

a If `jobz = job::vec`, then on exit this buffer is overwritten by the orthogonal matrix Z which contains the eigenvectors of A .

w Buffer, size at least n . Contains the eigenvalues of the matrix A in ascending order.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, and `jobz = oneapi::mkl::job::novec`, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If `info = i`, and `jobz = oneapi::mkl::job::vec`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n + 1)$ through $\text{mod}(info, n + 1)$.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

syevd (USM Version)

Syntax

```

namespace oneapi::mkl::lapack {
    cl::sycl::event syevd(cl::sycl::queue &queue, jobz jobz, oneapi::mkl::uplo upper_lower,
        ↪ std::int64_t n, T *a, std::int64_t lda, T *w, T *scratchpad, std::int64_t scratchpad_
        ↪ size, const std::vector<cl::sycl::event> &events = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

jobz Must be `job::novec` or `job::vec`.

If `jobz = job::novec`, then only eigenvalues are computed.

If `jobz = job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = job::upper`, a stores the upper triangular part of A .

If `upper_lower = job::lower`, a stores the lower triangular part of A .

n The order of the matrix A ($0 \leq n$).

a Pointer to array containing A , size $(lda, *)$. The second dimension of a must be at least $\max(1, n)$.

lda The leading dimension of a . Must be at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `syevd_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a If `jobz = job::vec`, then on exit this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A .

w Pointer to array of size at least n . Contains the eigenvalues of the matrix A in ascending order.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, and `jobz = oneapi::mkl::job::novec`, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If `info = i`, and `jobz = oneapi::mkl::job::vec`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $\text{info}/(n + 1)$ through $\text{mod}(\text{info}, n + 1)$.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

syevd_scratchpad_size

Computes size of scratchpad memory required for *syevd* function.

Description

`syevd_scratchpad_size` supports the following precisions.

T
float
double

Computes the number of elements of type T the scratchpad memory to be passed to *syevd* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

syevd_scratchpad_size**Syntax**

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t syevd_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::job jobz,
        ↪ oneapi::mkl::uplo upper_lower, std::int64_t n, std::int64_t lda)
}

```

Input Parameters

queue Device queue where calculations by *syevd* function will be performed.

jobz Must be `job::novec` or `job::vec`.

If `jobz = job::novec`, then only eigenvalues are computed.

If `jobz = job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = job::upper`, a stores the upper triangular part of A .

If `upper_lower = job::lower`, a stores the lower triangular part of A .

n The order of the matrix A ($0 \leq n$).

lda The leading dimension of `a`. Currently `lda` is not referenced in this function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type `T` the scratchpad memory to be passed to *syevd* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

sygvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem using a divide and conquer method.

Description

`sygvd` supports the following precisions.

T
float
double

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$Ax = \lambda Bx, ABx = \lambda x, \text{ or } BAx = \lambda x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

It uses a divide and conquer algorithm.

sygvd (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void sygvd(cl::sycl::queue &queue, std::int64_t itype, oneapi::mkl::job jobz,
    ↪oneapi::mkl::uplo upper_lower, std::int64_t n, cl::sycl::buffer<T,1> &a, std::int64_t
    ↪lda, cl::sycl::buffer<T,1> &b, std::int64_t ldb, cl::sycl::buffer<T,1> &w,
    ↪cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

itype Must be 1 or 2 or 3. Specifies the problem type to be solved:

if $itype = 1$, the problem type is $Ax = \lambda Bx$;

if $itype = 2$, the problem type is $ABx = \lambda x$;

if $itype = 3$, the problem type is $BAx = \lambda x$.

jobz Must be `job::novec` or `job::vec`.

If $jobz = job::novec$, then only eigenvalues are computed.

If $jobz = job::vec$, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If $upper_lower = job::upper$, **a** and **b** store the upper triangular part of A and B .

If $upper_lower = job::lower$, **a** and **b** stores the lower triangular part of A and B .

n The order of the matrices A and B ($0 \leq n$).

a Buffer, size `a(lda, *)` contains the upper or lower triangle of the symmetric matrix A , as specified by `upper_lower`. The second dimension of **a** must be at least $\max(1, n)$.

lda The leading dimension of **a**; at least $\max(1, n)$.

b Buffer, size `b(ldb, *)` contains the upper or lower triangle of the symmetric matrix B , as specified by `upper_lower`. The second dimension of **b** must be at least $\max(1, n)$.

ldb The leading dimension of **b**; at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `sygvd_scratchpad_size` function.

Output Parameters

- a** On exit, if `jobz = job::vec`, then if `info = 0`, `a` contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:
- if `itype = 1` or `2`, $Z^T B Z = I$;
 - if `itype = 3`, $Z^T B^{-1} Z = I$;
- If `jobz = job::novec`, then on exit the upper triangle (if `upper_lower = uplo::upper`) or the lower triangle (if `upper_lower = uplo::lower`) of A , including the diagonal, is destroyed.
- b** On exit, if `info ≤ n`, the part of `b` containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^T U$ or $B = L L^T$.
- w** Buffer, size at least n . If `info = 0`, contains the eigenvalues of the matrix A in ascending order.
- scratchpad** Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

For `info ≤ n`:

If `info = i`, and `jobz = oneapi::mkl::job::novec`, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If `info = i`, and `jobz = oneapi::mkl::job::vec`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns `info/(n + 1)` through `mod(info, n + 1)`.

For `info > n`:

If `info = n + i`, for $1 ≤ i ≤ n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

sygvd (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event sygvd(cl::sycl::queue &queue, std::int64_t itype, oneapi::mkl::job_
    ↪ jobz, oneapi::mkl::uplo upper_lower, std::int64_t n, T *a, std::int64_t lda, T *b,
    ↪ std::int64_t ldb, T *w, T *scratchpad, std::int64_t scratchpad_size, const std::vector
    ↪ <cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

itype Must be 1 or 2 or 3. Specifies the problem type to be solved:

if `itype = 1`, the problem type is $Ax = \lambda Bx$;

if `itype = 2`, the problem type is $ABx = \lambda x$;

if `itype = 3`, the problem type is $BAx = \lambda x$.

jobz Must be `job::novec` or `job::vec`.

If `jobz = job::novec`, then only eigenvalues are computed.

If `jobz = job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = job::upper`, `a` and `b` store the upper triangular part of A and B .

If `upper_lower = job::lower`, `a` and `b` stores the lower triangular part of A and B .

n The order of the matrices A and B ($0 \leq n$).

a Pointer to array of size `a(lda, *)` containing the upper or lower triangle of the symmetric matrix A , as specified by `upper_lower`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`; at least $\max(1, n)$.

b Pointer to array of size `b(ldb, *)` contains the upper or lower triangle of the symmetric matrix B , as specified by `upper_lower`. The second dimension of `b` must be at least $\max(1, n)$.

ldb The leading dimension of `b`; at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `sygvd_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

- a** On exit, if `jobz = job::vec`, then if `info = 0`, `a` contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:
- if `itype = 1` or `2`, $Z^T B Z = I$;
 - if `itype = 3`, $Z^T B^{-1} Z = I$;
- If `jobz = job::novec`, then on exit the upper triangle (if `upper_lower = uplo::upper`) or the lower triangle (if `upper_lower = uplo::lower`) of A , including the diagonal, is destroyed.
- b** On exit, if `info ≤ n`, the part of `b` containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^T U$ or $B = L L^T$.
- w** Pointer to array of size at least `n`. If `info = 0`, contains the eigenvalues of the matrix A in ascending order.
- scratchpad** Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

For `info ≤ n`:

If `info = i`, and `jobz = oneapi::mkl::job::novec`, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If `info = i`, and `jobz = oneapi::mkl::job::vec`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns `info/(n + 1)` through `mod(info, n + 1)`.

For `info > n`:

If `info = n + i`, for $1 ≤ i ≤ n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

sygvd_scratchpad_size

Computes size of scratchpad memory required for *sygvd* function.

Description

sygvd_scratchpad_size supports the following precisions.

T
float
double

Computes the number of elements of type T the scratchpad memory to be passed to *sygvd* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

sygvd_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t sygvd_scratchpad_size(cl::sycl::queue &queue, std::int64_t itype,
        ↪ oneapi::mkl::job jobz, oneapi::mkl::uplo upper_lower, std::int64_t n, std::int64_t lda,
        ↪ std::int64_t ldb)
    }
}
```

Input Parameters

queue Device queue where calculations by *sygvd* function will be performed.

itype Must be 1 or 2 or 3. Specifies the problem type to be solved:

if *itype* = 1, the problem type is $Ax = \lambda Bx$;

if *itype* = 2, the problem type is $ABx = \lambda x$;

if *itype* = 3, the problem type is $BAx = \lambda x$.

jobz Must be `job::novec` or `job::vec`.

If *jobz* = `job::novec`, then only eigenvalues are computed.

If *jobz* = `job::vec`, then eigenvalues and eigenvectors are computed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If *upper_lower* = `job::upper`, *a* and *b* store the upper triangular part of *A* and *B*.

If *upper_lower* = `job::lower`, *a* and *b* stores the lower triangular part of *A* and *B*.

n The order of the matrices A and B ($0 \leq n$).

lda The leading dimension of a .

ldb The leading dimension of b .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *sygvd* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

sytrd

Reduces a real symmetric matrix to tridiagonal form.

Description

sytrd supports the following precisions.

T
float
double

The routine reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = QTQ^T$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n - 1$ elementary reflectors. Routines are provided for working with Q in this representation .

sytrd (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void sytrd(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &d, cl::sycl::buffer
    ↪ <T,1> &e, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &scratchpad, std::int64_t
    ↪ scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, `a` stores the upper triangular part of A .

If `upper_lower = uplo::lower`, `a` stores the lower triangular part of A .

n The order of the matrices A ($0 \leq n$).

a The buffer `a`, size `(lda,*)`. Contains the upper or lower triangle of the symmetric matrix A , as specified by `upper_lower`.

The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`; at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `sytrd_scratchpad_size` function.

Output Parameters

a On exit,

if `upper_lower = uplo::upper`, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the buffer `tau`, represent the orthogonal matrix Q as a product of elementary reflectors;

if `upper_lower = uplo::lower`, the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the buffer `tau`, represent the orthogonal matrix Q as a product of elementary reflectors.

d Buffer containing the diagonal elements of the matrix T . The dimension of `d` must be at least $\max(1, n)$.

e Buffer containing the off diagonal elements of the matrix T . The dimension of `e` must be at least $\max(1, n - 1)$.

tau Buffer, size at least $\max(1, n)$. Stores $(n - 1)$ scalars that define elementary reflectors in decomposition of the unitary matrix Q in a product of $n - 1$ elementary reflectors. $\tau(n)$ is used as workspace.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If $\text{info} = -i$, the i -th parameter had an illegal value.

If info equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

sytrd (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event sytrd(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
    ↪ std::int64_t n, T *a, std::int64_t lda, T *d, T *e, T *tau, T *scratchpad, std::int64_t
    ↪ scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, `a` stores the upper triangular part of A .

If `upper_lower = uplo::lower`, `a` stores the lower triangular part of A .

n The order of the matrices A ($0 \leq n$).

a The pointer to matrix A , size $(\text{lda}, *)$. Contains the upper or lower triangle of the symmetric matrix A , as specified by `upper_lower`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a`; at least $\max(1, n)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by `sytrd_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a On exit,

if `upper_lower = uplo::upper`, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array `tau`, represent the orthogonal matrix Q as a product of elementary reflectors;

if `upper_lower = uplo::lower`, the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array `tau`, represent the orthogonal matrix Q as a product of elementary reflectors.

d Pointer to diagonal elements of the matrix T . The dimension of `d` must be at least $\max(1, n)$.

e Pointer to off diagonal elements of the matrix T . The dimension of `e` must be at least $\max(1, n - 1)$.

tau Pointer to array of size at least $\max(1, n)$. Stores $(n - 1)$ scalars that define elementary reflectors in decomposition of the unitary matrix Q in a product of $n - 1$ elementary reflectors. $\tau(n)$ is used as workspace.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the *i*-th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

sytrd_scratchpad_size

Computes size of scratchpad memory required for *sytrd* function.

Description

`sytrd_scratchpad_size` supports the following precisions.

T
float
double

Computes the number of elements of type T the scratchpad memory to be passed to *sytrd* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

sytrd_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
    std::int64_t sytrd_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
↳lower, std::int64_t n, std::int64_t lda)
}

```

Input Parameters

queue Device queue where calculations by *sytrd* function will be performed.

upper_lower Must be `uplo::upper` or `uplo::lower`.

If `upper_lower = uplo::upper`, a stores the upper triangular part of *A*.

If `upper_lower = uplo::lower`, a stores the lower triangular part of *A*.

n The order of the matrices *A* ($0 \leq n$).

lda The leading dimension of *a*.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type *T* the scratchpad memory to be passed to *sytrd* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

ungbr

Generates the complex unitary matrix *Q* or P^t determined by *gebrd*.

Description

ungbr supports the following precisions.

T
std::complex<float>
std::complex<double>

The routine generates the whole or part of the unitary matrices Q and P^H formed by the routines *gebrd*. All valid combinations of arguments are described in *Input Parameters*; in most cases you need the following:

To compute the whole $m \times m$ matrix Q , use:

```
oneapi::mkl::lapack::ungbr(queue, generate::q, m, m, n, a, ...)
```

(note that the buffer *a* must have at least m columns).

To form the n leading columns of Q if $m > n$, use:

```
oneapi::mkl::lapack::ungbr(queue, generate::q, m, n, n, a, ...)
```

To compute the whole $n \times n$ matrix P^T , use:

```
oneapi::mkl::lapack::ungbr(queue, generate::p, n, n, m, a, ...)
```

(note that the array *a* must have at least n rows).

To form the m leading rows of P^T if $m < n$, use:

```
oneapi::mkl::lapack::ungbr(queue, generate::p, m, n, m, a, ...)
```

ungbr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void ungbr(cl::sycl::queue &queue, oneapi::mkl::generate gen, std::int64_t m,
    ↪ std::int64_t n, std::int64_t k, cl::sycl::buffer<T,1> &a, std::int64_t lda,
    ↪ cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_
    ↪ size)
}
```

Input Parameters

queue The queue where the routine should be executed.

gen Must be `generate::q` or `generate::p`.

If `gen = generate::q`, the routine generates the matrix Q .

If `gen = generate::p`, the routine generates the matrix P^T .

m The number of rows in the matrix Q or P^T to be returned ($0 \leq m$).

If `gen = generate::q`, $m \geq n \geq \min(m, k)$.

If `gen = generate::p`, $n \geq m \geq \min(n, k)$.

n The number of columns in the matrix Q or P^T to be returned ($0 \leq n$). See `m` for constraints.

k If `gen = generate::q`, the number of columns in the original $m \times k$ matrix returned by *gebrd*.

If `gen = generate::p`, the number of rows in the original $k \times n$ matrix returned by *gebrd*.

a The buffer `a` as returned by *gebrd*.

lda The leading dimension of `a`.

tau For `gen = generate::q`, the array `tauq` as returned by *gebrd*. For `gen = generate::p`, the array `taup` as returned by *gebrd*.

The dimension of `tau` must be at least $\max(1, \min(m, k))$ for `gen = generate::q`, or $\max(1, \min(m, k))$ for `gen = generate::p`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by *ungbr_scratchpad_size* function.

Output Parameters

a Overwritten by n leading columns of the $m \times m$ unitary matrix Q or P^T , (or the leading rows or columns thereof) as specified by `gen`, `m`, and `n`.

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

ungbr (USM Version)

Syntax

```

namespace oneapi::mkl::lapack {
    cl::sycl::event ungbr(cl::sycl::queue &queue, oneapi::mkl::generate gen, std::int64_t
    ↪m, std::int64_t n, std::int64_t k, T *a, std::int64_t lda, T *tau, T *scratchpad,
    ↪std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}

```

Input Parameters

queue The queue where the routine should be executed.

gen Must be `generate::q` or `generate::p`.

If `gen = generate::q`, the routine generates the matrix Q .

If `gen = generate::p`, the routine generates the matrix P^T .

m The number of rows in the matrix Q or P^T to be returned ($0 \geq m$).

If `gen = generate::q`, $m \geq n \geq \min(m, k)$.

If `gen = generate::p`, $n \geq m \geq \min(n, k)$.

n The number of columns in the matrix Q or P^T to be returned ($0 \leq n$). See **m** for constraints.

k If `gen = generate::q`, the number of columns in the original $m \times k$ matrix returned by *gebrd*.

If `gen = generate::p`, the number of rows in the original $k \times n$ matrix returned by *gebrd*.

a The pointer to **a** as returned by *gebrd*.

lda The leading dimension of **a**.

tau For `gen = generate::q`, the array **tauq** as returned by *gebrd*. For `gen = generate::p`, the array **taup** as returned by *gebrd*.

The dimension of **tau** must be at least $\max(1, \min(m, k))$ for `gen = generate::q`, or $\max(1, \min(m, k))$ for `gen = generate::p`.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T . Size should not be less than the value returned by *ungbr_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by n leading columns of the $m \times m$ unitary matrix Q or P^T , (or the leading rows or columns thereof) as specified by **gen**, **m**, and **n**.

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

ungbr_scratchpad_size

Computes size of scratchpad memory required for *ungbr* function.

Description

`ungbr_scratchpad_size` supports the following precisions.

<code>T</code>
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to *ungbr* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

ungbr_scratchpad_size

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t ungbr_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::generate gen,
        ↪ std::int64_t m, std::int64_t n, std::int64_t k, std::int64_t lda, std::int64_t &
        ↪ scratchpad_size)
    }

```

Input Parameters

queue Device queue where calculations by *ungbr* function will be performed.

gen Must be `generate::q` or `generate::p`.

If `gen = generate::q`, the routine generates the matrix Q .

If `gen = generate::p`, the routine generates the matrix P^T .

m The number of rows in the matrix Q or P^T to be returned ($0 \leq m$).

If `gen = generate::q`, $m \geq n \geq \min(m, k)$.

If `gen = generate::p`, $n \geq m \geq \min(n, k)$.

n The number of columns in the matrix Q or P^T to be returned ($0 \leq n$). See `m` for constraints.

k If `gen = generate::q`, the number of columns in the original $m \times k$ matrix reduced by *gebrd*.

If `gen = generate::p`, the number of rows in the original $k \times n$ matrix reduced by *gebrd*.

lda The leading dimension of `a`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *ungbr* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

ungtr

Generates the complex unitary matrix Q determined by *hetrd*.

Description

ungtr supports the following precisions.

T
std::complex<float>
std::complex<double>

The routine explicitly generates the $n \times n$ unitary matrix Q formed by *hetrd* when reducing a complex Hermitian matrix A to tridiagonal form: $A = QTQ^H$. Use this routine after a call to *hetrd*.

ungtr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void ungtr(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower, std::int64_t n,
    ↪ cl::sycl::buffer<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &tau,
    ↪ cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Must be `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to *hetrd*.

n The order of the matrix Q ($0 \leq n$).

a The buffer `a` as returned by *hetrd*. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a` ($n \leq lda$).

tau The buffer `tau` as returned by *hetrd*. The dimension of `tau` must be at least $\max(1, n - 1)$.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by *ungtr_scratchpad_size* function.

Output Parameters

a Overwritten by the unitary matrix Q .

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

ungtr (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event ungtr(cl::sycl::queue &queue, oneapi::mkl::uplo upper_lower,
    ↪ std::int64_t n, T *a, std::int64_t lda, T *tau, T *scratchpad, std::int64_t scratchpad_
    ↪ size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue The queue where the routine should be executed.

upper_lower Must be `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to `hetrd`.

n The order of the matrix Q ($0 \leq n$).

a The pointer to `a` as returned by `hetrd`. The second dimension of `a` must be at least $\max(1, n)$.

lda The leading dimension of `a` ($n \leq lda$).

tau The pointer to `tau` as returned by `hetrd`. The dimension of `tau` must be at least $\max(1, n - 1)$.

scratchpad_size Size of `scratchpad` memory as a number of floating point elements of type `T`. Size should not be less than the value returned by `ungtr_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Overwritten by the unitary matrix Q .

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

ungtr_scratchpad_size

Computes size of scratchpad memory required for *ungtr* function.

Description

`ungtr_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Computes the number of elements of type T the scratchpad memory to be passed to *ungtr* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

ungtr_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t ungtr_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::uplo upper_
        ↪lower, std::int64_t n, std::int64_t lda)
    }
}
```

Input Parameters

queue Device queue where calculations by *ungtr* function will be performed.

upper_lower Must be `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to *hetrd*.

n The order of the matrix Q ($0 \leq n$).

lda The leading dimension of a ($n \leq lda$).

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *ungtr* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

unmtr

Multiplies a complex matrix by the complex unitary matrix Q determined by *hetrd*.

Description

`unmtr` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

The routine multiplies a complex matrix C by Q or Q^H , where Q is the unitary matrix Q formed by *hetrd* when reducing a complex Hermitian matrix A to tridiagonal form: $A = QTQ^H$. Use this routine after a call to *hetrd*.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products QC , $Q^H C$, CQ , or CQ^H (overwriting the result on C).

unmtr (Buffer Version)

Syntax

```
namespace oneapi::mkl::lapack {
    void unmtr(cl::sycl::queue &queue, oneapi::mkl::side side, oneapi::mkl::uplo upper_
    ↪lower, oneapi::mkl::transpose trans, std::int64_t m, std::int64_t n, cl::sycl::buffer
    ↪<T,1> &a, std::int64_t lda, cl::sycl::buffer<T,1> &tau, cl::sycl::buffer<T,1> &c,
    ↪std::int64_t ldc, cl::sycl::buffer<T,1> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

In the descriptions below, r denotes the order of Q :

$r=m$	if <code>side = side::left</code>
$r=n$	if <code>side = side::right</code>

queue The queue where the routine should be executed.

side Must be either `side::left` or `side::right`.

If `side=side::left`, Q or Q^H is applied to C from the left.

If `side=side::right`, Q or Q^H is applied to C from the right.

upper_lower Must be either `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to *hetrd*.

trans Must be either `transpose::nontrans` or `transpose::conjtrans`.

If `trans=transpose::nontrans`, the routine multiplies C by Q .

If `trans=transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($m \geq 0$).

n The number of columns the matrix C ($n \geq 0$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a The buffer `a` as returned by *hetrd*.

lda The leading dimension of `a` ($\max(1, r) \leq \text{lda}$).

tau The buffer `tau` as returned by *hetrd*. The dimension of `tau` must be at least $\max(1, r - 1)$.

c The buffer `c` contains the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c` ($\max(1, n) \leq \text{ldc}$).

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by *unmtr_scratchpad_size* function.

Output Parameters

c Overwritten by the product QC , $Q^H C$, CQ , or CQ^H (as specified by `side` and `trans`).

scratchpad Buffer holding scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::host_bad_alloc`

`oneapi::mkl::device_bad_alloc`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

`oneapi::mkl::lapack::computation_error`

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -i`, the i -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by `detail()` method of exception object.

unmtr (USM Version)

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event unmtr(cl::sycl::queue &queue, oneapi::mkl::side side,
        ↪ oneapi::mkl::uplo upper_lower, oneapi::mkl::transpose trans, std::int64_t m,
        ↪ std::int64_t n, T *a, std::int64_t lda, T *tau, T *c, std::int64_t ldc, T *scratchpad,
        ↪ std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

In the descriptions below, r denotes the order of Q :

$r=m$	if <code>side = side::left</code>
$r=n$	if <code>side = side::right</code>

queue The queue where the routine should be executed.

side Must be either `side::left` or `side::right`.

If `side=side::left`, Q or Q^H is applied to C from the left.

If `side=side::right`, Q or Q^H is applied to C from the right.

upper_lower Must be either `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to *hetrd*.

trans Must be either `transpose::nontrans` or `transpose::conjtrans`.

If `trans=transpose::nontrans`, the routine multiplies C by Q .

If `trans=transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($m \geq 0$).

n The number of columns the matrix C ($n \geq 0$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a The pointer to `a` as returned by *hetrd*.

lda The leading dimension of `a` ($\max(1, r) \leq \text{lda}$).

tau The pointer to `tau` as returned by *hetrd*. The dimension of `tau` must be at least $\max(1, r - 1)$.

c The array `c` contains the matrix C . The second dimension of `c` must be at least $\max(1, n)$.

ldc The leading dimension of `c` ($\max(1, n) \leq \text{ldc}$).

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by *unmtr_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

c Overwritten by the product QC , $Q^H C$, CQ , or CQ^H (as specified by `side` and `trans`).

scratchpad Pointer to scratchpad memory to be used by routine for storing intermediate results.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::host_bad_alloc

oneapi::mkl::device_bad_alloc

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

oneapi::mkl::lapack::computation_error

Exception is thrown in case of problems during calculations. The `info` code of the problem can be obtained by *info()* method of exception object:

If *info* = $-i$, the i -th parameter had an illegal value.

If *info* equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should not be less than value return by *detail()* method of exception object.

Return Values

Output event to wait on to ensure computation is complete.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

unmtr_scratchpad_size

Computes size of scratchpad memory required for *unmtr* function.

Description

unmtr_scratchpad_size supports the following precisions.

T
std::complex<float>
std::complex<double>

Computes the number of elements of type T the scratchpad memory to be passed to *unmtr* function should be able to hold. Calls to this routine must specify the template parameter explicitly.

unmtr_scratchpad_size

Syntax

```
namespace oneapi::mkl::lapack {
  template <typename T>
  std::int64_t unmtr_scratchpad_size(cl::sycl::queue &queue, oneapi::mkl::side side,
  ↪oneapi::mkl::uplo upper_lower, oneapi::mkl::transpose trans, std::int64_t m,
  ↪std::int64_t n, std::int64_t lda, std::int64_t ldc)
}
```

Input Parameters

queue Device queue where calculations by *unmtr* function will be performed.

side Must be either `side::left` or `side::right`.

If `side=side::left`, Q or Q^H is applied to C from the left.

If `side=side::right`, Q or Q^H is applied to C from the right.

upper_lower Must be either `uplo::upper` or `uplo::lower`. Uses the same `upper_lower` as supplied to *hetrd*.

trans Must be either `transpose::nontrans` or `transpose::conjtrans`.

If `trans=transpose::nontrans`, the routine multiplies C by Q .

If `trans=transpose::conjtrans`, the routine multiplies C by Q^H .

m The number of rows in the matrix C ($m \geq 0$).

n The number of columns the matrix C ($n \geq 0$).

k The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

lda The leading dimension of a ($\max(1, r) \leq \text{lda}$).

ldc The leading dimension of c ($\max(1, n) \leq \text{ldc}$).

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Return Value

The number of elements of type T the scratchpad memory to be passed to *unmtr* function should be able to hold.

Parent topic: *LAPACK Singular Value and Eigenvalue Problem Routines*

LAPACK-like Extensions Routines

oneAPI Math Kernel Library DPC++ provides additional routines to extend the functionality of the LAPACK routines. These include routines to compute many independent factorizations, linear equation solutions, and similar. The following table lists the LAPACK-like Extensions routine groups.

Routines	Scratchpad Size Routines	Description
<i>geqrf_batch</i>	<i>geqrf_batch_scratchpad</i>	Computes the QR factorizations of a batch of general matrices.
<i>getrf_batch</i>	<i>getrf_batch_scratchpad</i>	Computes the LU factorizations of a batch of general matrices.
<i>getri_batch</i>	<i>getri_batch_scratchpad</i>	Computes the inverses of a batch of LU-factored general matrices.
<i>getrs_batch</i>	<i>getrs_batch_scratchpad</i>	Solves systems of linear equations with a batch of LU-factored square coefficient matrices, with multiple right-hand sides.
<i>orgqr_batch</i>	<i>orgqr_batch_scratchpad</i>	Generates the real orthogonal/complex unitary matrix Q_i of the QR factorization formed by <i>geqrf_batch</i> .
<i>potrf_batch</i>	<i>potrf_batch_scratchpad</i>	Computes the Cholesky factorization of a batch of symmetric (Hermitian) positive-definite matrices.
<i>potrs_batch</i>	<i>potrs_batch_scratchpad</i>	Solves systems of linear equations with a batch of Cholesky-factored symmetric (Hermitian) positive-definite coefficient matrices, with multiple right-hand sides.
<i>ungqr_batch</i>	<i>ungqr_batch_scratchpad</i>	Generates the complex unitary matrix Q_i with the QR factorization formed by <i>geqrf_batch</i> .

geqrf_batch

Computes the QR factorizations of a batch of general matrices.

Description

`geqrf_batch` supports the following precisions.

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

geqrf_batch (Buffer Version)

Description

The buffer version of `geqrf_batch` supports only the strided API.

Strided API

Syntax

```

namespace oneapi::mkl::lapack {
    void geqrf_batch(cl::sycl::queue &queue, std::int64_t m, std::int64_t n,
        ↪ cl::sycl::buffer<T> &a, std::int64_t lda, std::int64_t stride_a, cl::sycl::buffer<T> &
        ↪ tau, std::int64_t stride_tau, std::int64_t batch_size, cl::sycl::buffer<T> &scratchpad,
        ↪ std::int64_t scratchpad_size)
}

```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in matrices A_i ($0 \leq m$).

n Number of columns in matrices A_i ($0 \leq n$).

a Array holding input matrices A_i .

lda Leading dimension of matrices A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

stride_tau Stride between the beginnings of arrays τ_i inside the array **tau**.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as the number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the `geqrf_batch_scratchpad_size` function.

Output Parameters

- a** Factorization data as follows: The elements on and above the diagonal of A_i contain the $\min(m, n) \times n$ upper trapezoidal matrices R_i (R_i is upper triangular if $m \geq n$); the elements below the diagonal, with the array τ_i , contain the orthogonal matrix Q_i as a product of $\min(m, n)$ elementary reflectors.
- tau** Array to store batch of τ_i , each of size $\min(m, n)$, containing scalars that define elementary reflectors for the matrices Q_i in its decomposition in a product of elementary reflectors.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The **info** code of the problem can be obtained by *info()* method of exception object:

If **info** = -*n*, the *n*-th parameter had an illegal value.

If **info** equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by *detail()* method of exception object.

If **info** is not zero and *detail()* returns zero, then there were some errors for some of the problems in the supplied batch and **info** code contains the number of failed calculations in a batch.

geqrf_batch (USM Version)

Description

The USM version of `geqrf_batch` supports the group API and strided API.

Group API

The routine forms the $Q_i R_i$ factorizations of a general $m \times n$ matrices A_i , $i \in \{1 \dots \text{batch_size}\}$, where **batch_size** is the sum of all parameter group sizes as provided with **group_sizes** array. No pivoting is performed during factorization. The routine does not form the matrices Q_i explicitly. Instead, Q_i is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q_i in this representation. The total number of problems to solve, **batch_size**, is a sum of sizes of all of the groups of parameters as provided by **group_sizes** array.

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event geqrf_batch(cl::sycl::queue &queue, std::int64_t *m, std::int64_t *n,
    ↪ T **a, std::int64_t *lda, T **tau, std::int64_t group_count, std::int64_t *group_sizes,
    ↪ T *scratchpad, std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &
    ↪ events = {})
}
```

Input Parameters

queue Device queue where calculations will be performed.

m Array of `group_count` m_g parameters. Each m_g specifies the number of rows in matrices A_i from array `a`, belonging to group g .

n Array of `group_count` n_g parameters. Each n_g specifies the number of columns in matrices A_i from array `a`, belonging to group g .

a Array of `batch_size` pointers to input matrices A_i , each of size $\text{lda}_g \cdot n_g$ (g is an index of group to which A_i belongs)

lda Array of `group_count` lda_g parameters, each representing the leading dimensions of input matrices A_i from array `a`, belonging to group g .

group_count Specifies the number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as the number of floating point elements of type `T`. Size should not be less than the value returned by the Group API of the `geqrf_batch_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Factorization data as follows: The elements on and above the diagonal of A_i contain the $\min(m_g, n_g) \times n_g$ upper trapezoidal matrices R_i (R_i is upper triangular if $m_g \geq n_g$); the elements below the diagonal, with the array τ_i , contain the orthogonal matrix Q_i as a product of $\min(m_g, n_g)$ elementary reflectors. Here g is the index of the parameters group corresponding to the i -th decomposition.

tau Array of pointers to store arrays τ_i , each of size $\min(m_g, n_g)$, containing scalars that define elementary reflectors for the matrices Q_i in its decomposition in a product of elementary reflectors. Here g is the index of the parameters group corresponding to the i -th decomposition.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

Strided API

The routine forms the $Q_i R_i$ factorizations of general $m \times n$ matrices A_i . No pivoting is performed. The routine does not form the matrices Q_i explicitly. Instead, Q_i is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q_i in this representation.

Syntax

```
namespace oneapi::mkl::lapack {
    sycl::event geqrf_batch(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, T *a,
        ↪ std::int64_t lda, std::int64_t stride_a, T *tau, std::int64_t stride_tau, std::int64_t
        ↪ batch_size, T *scratchpad, std::int64_t scratchpad_size, const std::vector
        ↪ <cl::sycl::event> &events = {})
}
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in matrices A_i ($0 \leq m$).

n Number of columns in matrices A_i ($0 \leq n$).

a Array holding input matrices A_i .

lda Leading dimensions of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array `a`.

stride_tau Stride between the beginnings of arrays τ_i inside the array `tau`.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as the number of floating point elements of type `T`. Size should not be less than the value returned by the Strided API of the `geqrf_batch_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

- a** Factorization data as follows: The elements on and above the diagonal of A_i contain the $\min(m, n) \times n$ upper trapezoidal matrices R_i (R_i is upper triangular if $m \geq n$); the elements below the diagonal, with the array τ_i , contain the orthogonal matrix Q_i as a product of $\min(m, n)$ elementary reflectors.
- tau** Array to store batch of τ_i , each of size $\min(m, n)$, containing scalars that define elementary reflectors for the matrices Q_i in its decomposition in a product of elementary reflectors.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::lapack::batch_error`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

Parent topic: *LAPACK-like Extensions Routines*

geqrf_batch_scratchpad_size

Computes size of scratchpad memory required for the `geqrf_batch` function.

Description

`geqrf_batch_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Group API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the `geqrf_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t geqrf_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t *m,
        ↪ std::int64_t *n, std::int64_t *lda, std::int64_t group_count, std::int64_t *group_
        ↪ sizes)
}

```

Input Parameters

queue Device queue where calculations will be performed.

m

Array of `group_count` m_g parameters.

Each of m_g specifies the number of rows in the matrices A_i belonging to group g .

n

Array of `group_count` n_g parameters.

Each of n_g specifies the number of columns in the matrices A_i belonging to group g .

lda Array of `group_count` lda_g parameters, each representing the leading dimensions of input matrices belonging to group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the `geqrf_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Strided API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the `geqrf_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t geqrf_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t m,
        ↪std::int64_t n, std::int64_t lda, std::int64_t stride_a, std::int64_t stride_tau,
        ↪std::int64_t batch_size)
};
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in the matrices A_i ($0 \leq m$).

n Number of columns in A_i ($0 \leq n$).

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array a.

stride_tau Stride between the beginnings of arrays τ_i inside the array tau.

batch_size Number of problems in a batch.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the *geqrf_batch* function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

getrf_batch

Computes the LU factorizations of a batch of general matrices.

Description

`getrf_batch` supports the following precisions.

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

`getrf_batch` (Buffer Version)

Description

The buffer version of `getrf_batch` supports only the strided API.

Strided API

The routine computes the LU factorizations of general $m \times n$ matrices A_i as $A_i = P_i L_i U_i$, where P_i is a permutation matrix, L_i is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U_i is upper triangular (upper trapezoidal if $m < n$). The routine uses partial pivoting, with row interchanges.

Syntax

```
namespace oneapi::mkl::lapack {
    void getrf_batch(cl::sycl::queue &queue, std::int64_t m, std::int64_t n,
        ↪ cl::sycl::buffer<T> &a, std::int64_t lda, std::int64_t stride_a, cl::sycl::buffer
        ↪ <std::int64_t> &ipiv, std::int64_t stride_ipiv, std::int64_t batch_size,
        ↪ cl::sycl::buffer<T> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in matrices A_i ($0 \leq m$).

n Number of columns in matrices A_i ($0 \leq n$).

a Array holding input matrices A_i .

lda Leading dimension of matrices A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

stride_ipiv Stride between the beginnings of arrays $ipiv_i$ inside the array **ipiv**.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the `getrf_batch_scratchpad_size` function.

Output Parameters

a L_i and U_i . The unit diagonal elements of L_i are not stored.

ipiv Array containing batch of the pivot indices $ipiv_i$ each of size at least $\max(1, \min(m, n))$; for $1 \leq k \leq \min(m, n)$, where row k of A_i was interchanged with row $ipiv_i(k)$.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The **info** code of the problem can be obtained by *info()* method of exception object:

If **info** = **-n**, the n -th parameter had an illegal value.

If **info** equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by *detail()* method of exception object.

If **info** is not zero and *detail()* returns zero, then there were some errors for some of the problems in the supplied batch and **info** code contains the number of failed calculations in a batch.

If **info** is positive, then the factorization has been completed, but some of U_i are exactly singular. Division by 0 will occur if you use the factor U_i for solving a system of linear equations.

The indices of such matrices in the batch can be obtained with *ids()* method of the exception object. The indices of first zero diagonal elements in these U_i matrices can be obtained by *exceptions()* method of exception object.

getrf_batch (USM Version)

Description

The USM version of `getrf_batch` supports the group API and strided API.

Group API

The routine computes the batch of LU factorizations of general $m \times n$ matrices A_i ($i \in \{1 \dots batch_size\}$) as $A_i = P_i L_i U_i$, where P_i is a permutation matrix, L_i is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U_i is upper triangular (upper trapezoidal if $m < n$). The routine uses partial pivoting, with row interchanges. Total number of problems to solve, `batch_size`, is a sum of sizes of all of the groups of parameters as provided by `group_sizes` array.

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event getrf_batch(cl::sycl::queue &queue, std::int64_t *m, std::int64_t *n,
    ↪ T **a, std::int64_t *lda, std::int64_t **ipiv, std::int64_t group_count, std::int64_t
    ↪ *group_sizes, T *scratchpad, std::int64_t scratchpad_size, const std::vector
    ↪ <cl::sycl::event> &events = {})
}
```

Input Parameters

queue Device queue where calculations will be performed.

m Array of `group_count` parameters m_g specifying the number of rows in matrices A_i ($0 \leq m_g$) belonging to group g .

n Array of `group_count` parameters n_g specifying the number of columns in matrices A_i ($0 \leq n_g$) belonging to group g .

a Array holding `batch_size` pointers to input matrices A_i .

lda Array of `group_count` parameters lda_g specifying the leading dimensions of A_i belonging to group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Group API of the `getrf_batch_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a L_i and U_i . The unit diagonal elements of L_i are not stored.

ipiv Arrays of `batch_size` pointers to arrays containing pivot indices $ipiv_i$ each of size at least $\max(1, \min(m_g, n_g))$; for $1 \leq k \leq \min(m_g, n_g)$, where row k of A_i was interchanged with row $ipiv_i(k)$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is positive, then the factorization has been completed, but some of U_i are exactly singular. Division by 0 will occur if you use the factor U_i for solving a system of linear equations.

The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The indices of first zero diagonal elements in these U_i matrices can be obtained by `exceptions()` method of exception object.

Strided API

The routine computes the LU factorizations of general $m \times n$ matrices A_i as $A_i = P_i L_i U_i$, where P_i is a permutation matrix, L_i is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U_i is upper triangular (upper trapezoidal if $m < n$). The routine uses partial pivoting, with row interchanges.

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event getrf_batch(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, T_
↪ *a, std::int64_t lda, std::int64_t stride_a, std::int64_t *ipiv, std::int64_t stride_
↪ ipiv, std::int64_t batch_size, T *scratchpad, std::int64_t scratchpad_size, const_
↪ std::vector<cl::sycl::event> &events = {})
};
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in matrices A_i ($0 \leq m$).

n Number of columns in matrices A_i ($0 \leq n$).

a Array holding input matrices A_i .

lda Leading dimension of matrices A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array `a`.

stride_ipiv Stride between the beginnings of arrays `ipivi` inside the array `ipiv`.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less then the value returned by the Strided API of the `getrf_batch_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a L_i and U_i . The unit diagonal elements of L_i are not stored.

ipiv Array containing batch of the pivot indices $ipiv_i$ each of size at least $\max(1, \min(m, n))$; for $1 \leq k \leq \min(m, n)$, where row k of A_i was interchanged with row $ipiv_i(k)$.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The **info** code of the problem can be obtained by *info()* method of exception object:

If **info** = **-n**, the n -th parameter had an illegal value.

If **info** equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by *detail()* method of exception object.

If **info** is not zero and *detail()* returns zero, then there were some errors for some of the problems in the supplied batch and **info** code contains the number of failed calculations in a batch.

If **info** is positive, then the factorization has been completed, but some of U_i are exactly singular. Division by 0 will occur if you use the factor U_i for solving a system of linear equations.

The indices of such matrices in the batch can be obtained with *ids()* method of the exception object. The indices of first zero diagonal elements in these U_i matrices can be obtained by *exceptions()* method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

getrf_batch_scratchpad_size

Computes size of scratchpad memory required for the *getrf_batch* function.

Description

getrf_batch_scratchpad_size supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Group API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the *getrf_batch* function.

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t getrf_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t *m,
        ↪ std::int64_t *n, std::int64_t *lda, std::int64_t group_count, std::int64_t *group_
        ↪ sizes)
}

```

Input Parameters

queue Device queue where calculations will be performed.

m Array of *group_count* parameters m_g specifying the number of rows in the matrices belonging to group g .

n Array of *group_count* parameters n_g specifying the number of columns in matrices belonging to group g .

lda Array of *group_count* parameters lda_g specifying the leading dimensions of matrices belonging to group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of *group_count* integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, *batch_size*, is a sum of all parameter group sizes.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the *getrf_batch* function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Strided API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the *getrf_batch* function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t getrf_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t m,
        ↪std::int64_t n, std::int64_t lda, std::int64_t stride_a, std::int64_t stride_ipiv,
        ↪std::int64_t batch_size)
};
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in the matrices A_i ($0 \leq m$).

n Number of columns in A_i ($0 \leq n$).

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

stride_ipiv Stride between the beginnings of arrays $ipiv_i$ inside the array **ipiv**.

batch_size Number of problems in a batch.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the *getrf_batch* function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

getrf_batch

Computes the inverses of a batch of LU-factored matrices determined by *getrf_batch*.

Description

`getri_batch` supports the following precisions.

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

`getri_batch` (Buffer Version)

Description

The buffer version of `getri_batch` supports only the strided API.

Strided API

The routine computes the inverses A_i^{-1} of general matrices A_i . Before calling this routine, call the Strided API of the `getrf_batch (Buffer Version)` function to factorize A_i .

Syntax

```
namespace oneapi::mkl::lapack {
    void getri_batch(cl::sycl::queue &queue, std::int64_t n, cl::sycl::buffer<T> &a,
    ↪ std::int64_t lda, std::int64_t stride_a, cl::sycl::buffer<std::int64_t> &ipiv,
    ↪ std::int64_t stride_ipiv, std::int64_t batch_size, cl::sycl::buffer<T> &scratchpad,
    ↪ std::int64_t scratchpad_size)
}
```

Input Parameters

queue Device queue where calculations will be performed.

n Order of the matrices A_i ($0 \leq n$).

a Result of the Strided API of the `getrf_batch (Buffer Version)` function.

lda Leading dimension of A_i ($n \leq lda$).

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

ipiv Arrays returned by the Strided API of the `getrf_batch (Buffer Version)` function.

stride_ipiv Stride between the beginnings of arrays $ipiv_i$ inside the array **ipiv**.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the `getri_batch_scratchpad_size` function.

Output Parameters

a Inverse $n \times n$ matrices A_i^{-1} .

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

getri_batch (USM Version)

Description

The USM version of `getri_batch` supports the group API and strided API.

Group API

The routine computes the inverses A_i^{-1} of general matrices A_i , $i \in \{1..batch_size\}$. Before calling this routine, call the Group API of the `getrf_batch (USM Version)` function to factorize A_i . Total number of problems to solve, `batch_size`, is a sum of sizes of all of the groups of parameters as provided by `group_sizes` array.

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event getri_batch(cl::sycl::queue &queue, std::int64_t *n, T **a, std::int64_t
    ↪ *lda, std::int64_t **ipiv, std::int64_t group_count, std::int64_t *group_sizes, T
    ↪ *scratchpad, std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events,
    ↪ = {})
}

```

Input Parameters

queue Device queue where calculations will be performed.

n Array of `group_count` n_g parameters specifying the order of the matrices A_i ($0 \leq n_g$) belonging to group g .

a Result of the Group API of the *getrf_batch (USM Version)* function.

lda Array of `group_count` lda_g parameters specifying the leading dimensions of the matrices A_i ($n_g \leq lda_g$) belonging to group g .

ipiv Arrays returned by the Group API of the *getrf_batch (USM Version)* function.

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Group API of the *getri_batch_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Inverse $n_g \times n_g$ matrices A_i^{-1} .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by *info()* method of exception object:

If `info` = `-n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by *detail()* method of exception object.

If `info` is not zero and *detail()* returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

Strided API

The routine computes the inverses A_i^{-1} of general matrices A_i . Before calling this routine, call the Strided API of the *getrf_batch (USM Version)* function to factorize A_i .

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event getri_batch(cl::sycl::queue &queue, std::int64_t n, T *a, std::int64_t
    ↪_lda, std::int64_t stride_a, std::int64_t *ipiv, std::int64_t stride_ipiv, std::int64_t
    ↪_batch_size, T *scratchpad, std::int64_t scratchpad_size, const std::vector
    ↪_cl::sycl::event> &events = {})
};
```

Input Parameters

queue Device queue where calculations will be performed.

n Order of the matrices A_i ($0 \leq n$).

a Result of the Strided API of the *getrf_batch (USM Version)* function.

lda Leading dimension of A_i ($n \leq lda$).

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

ipiv Arrays returned by the Strided API of the *getrf_batch (USM Version)* function.

stride_ipiv Stride between the beginnings of arrays $ipiv_i$ inside the array **ipiv**.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the *getri_batch_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Inverse $n \times n$ matrices A_i^{-1} .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The **info** code of the problem can be obtained by *info()* method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as `scratchpad` size, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

Parent topic: *LAPACK-like Extensions Routines*

getri_batch_scratchpad_size

Computed size of `scratchpad` memory required for the `getri_batch` function.

Description

`getri_batch_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Group API

Computes the number of elements of type T the `scratchpad` memory should be able to hold to be passed to the Group API of the `getri_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t getri_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t *n,
        ↪ std::int64_t *lda, std::int64_t group_count, std::int64_t *group_sizes)
}

```

Input Parameters

queue Device queue where calculations will be performed.

n Array of `group_count` n_g parameters specifying the order of the matrices belonging to group g .

lda Array of `group_count` lda_g parameters specifying the leading dimensions of the matrices belonging to group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the `getri_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Strided API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the `getri_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t getri_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t n,
        ↪ std::int64_t lda, std::int64_t stride_a, std::int64_t stride_ipiv, std::int64_t batch_
        ↪ size)
};
```

Input Parameters

queue Device queue where calculations will be performed.

n The order of the matrices A_i ($0 \leq n$).

lda Leading dimension of A_i ($n \leq lda$).

stride_a Stride between the beginnings of matrices A_i inside the batch array `a`.

stride_ipiv Stride between the beginnings of arrays $ipiv_i$ inside the array `ipiv`.

batch_size Specifies the number of problems in a batch.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the `getri_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::unimplemented`

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

getrs_batch

Solves a system of linear equations with a batch of LU-factored square coefficient matrices, with multiple right-hand sides.

Description

`getrs_batch` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

getrs_batch (Buffer Version)

Description

The buffer version of `getrs_batch` supports only the strided API.

Strided API

The routine solves for the following systems of linear equations X_i :

$A_i X_i = B_i$, if `trans=mkl::transpose::nontrans`

$A_i^T X_i = B_i$, if `trans=mkl::transpose::trans`

$A_i^H X_i = B_i$, if `trans=mkl::transpose::conjtrans`

Before calling this routine, the Strided API of the *getrf_batch (Buffer Version)* function should be called to compute the LU factorizations of A_i .

Syntax

```
namespace oneapi::mkl::lapack {
    void getsr_batch(cl::sycl::queue &queue, mkl::transpose trans, std::int64_t n,
        ↪ std::int64_t nrhs, cl::sycl::buffer<T> &a, std::int64_t lda, std::int64_t stride_a,
        ↪ cl::sycl::buffer<std::int64_t> &ipiv, std::int64_t stride_ipiv, cl::sycl::buffer<T> &b,
        ↪ std::int64_t ldb, std::int64_t stride_b, std::int64_t batch_size, cl::sycl::buffer<T>
        ↪ &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue Device queue where calculations will be performed.

trans

Form of the equations:

If `trans = mkl::transpose::nontrans`, then $A_i X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::trans`, then $A_i^T X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::conjtrans`, then $A_i^H X_i = B_i$ is solved for X_i .

n Order of the matrices A_i and the number of rows in matrices B_i ($0 \leq n$).

nrhs Number of right-hand sides ($0 \leq nrhs$).

a Array containing the factorizations of the matrices A_i , as returned the Strided API of the *getrf_batch (Buffer Version)* function.

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

ipiv `ipiv` array, as returned by the Strided API of the *getrf_batch (Buffer Version)* function.

stride_ipiv Stride between the beginnings of arrays `ipivi` inside the array `ipiv`.

b Array containing the matrices B_i whose columns are the right-hand sides for the systems of equations.

ldb Leading dimension of B_i .

stride_b Stride between the beginnings of matrices B_i inside the batch array **b**.

batch_size Specifies the number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the *getrs_batch_scratchpad_size* function.

Output Parameters

b Solution matrices X_i .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by *detail()* method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is zero, then diagonal element of some of U_i is zero, and the solve could not be completed. The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The indices of first zero diagonal elements in these U_i matrices can be obtained by `exceptions()` method of exception object.

getrs_batch (USM Version)

Description

The USM version of `getrs_batch` supports the group API and strided API.

Group API

The routine solves the following systems of linear equations for X_i ($i \in \{1 \dots batch_size\}$):

$A_i X_i = B_i$, if `trans=mkl::transpose::nontrans`

$A_i^T X_i = B_i$, if `trans=mkl::transpose::trans`

$A_i^H X_i = B_i$, if `trans=mkl::transpose::conjtrans`

Before calling this routine, call the Group API of the `getrf_batch (USM Version)` function to compute the LU factorizations of A_i .

Total number of problems to solve, `batch_size`, is a sum of sizes of all of the groups of parameters as provided by `group_sizes` array.

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event getsrs_batch(cl::sycl::queue &queue, mkl::transpose *trans, std::int64_t
    ↪ *n, std::int64_t *nrhs, T **a, std::int64_t *lda, std::int64_t **ipiv, T **b,
    ↪ std::int64_t *ldb, std::int64_t group_count, std::int64_t *group_sizes, T *scratchpad,
    ↪ std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue Device queue where calculations will be performed.

trans

Array of `group_count` parameters $trans_g$ indicating the form of the equations for the group g :

If `trans = mkl::transpose::nontrans`, then $A_i X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::trans`, then $A_i^T X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::conjtrans`, then $A_i^H X_i = B_i$ is solved for X_i .

n Array of `group_count` parameters n_g specifying the order of the matrices A_i and the number of rows in matrices B_i ($0 \leq n_g$) belonging to group g .

nrhs Array of `group_count` parameters $nrhs_g$ specifying the number of right-hand sides ($0 \leq nrhs_g$) for group g .

a Array of `batch_size` pointers to factorizations of the matrices A_i , as returned by the Group API of the `ref::onemkl_lapack_getrf_batch_usm` function.

lda Array of `group_count` parameters lda_g specifying the leading dimensions of A_i from group g .

ipiv ipiv array, as returned by the Group API of the *getrf_batch (USM Version)* function.

b The array containing `batch_size` pointers to the matrices B_i whose columns are the right-hand sides for the systems of equations.

ldb Array of `group_count` parameters ldb_g specifying the leading dimensions of B_i in the group g .

group_count Specifies the number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Group API of the *getrs_batch_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

b Solution matrices X_i .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of problems during calculations. The info code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is zero, then diagonal element of some of U_i is zero, and the solve could not be completed. The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The indices of first zero diagonal elements in these U_i matrices can be obtained by `exceptions()` method of exception object.

Strided API

The routine solves the following systems of linear equations for X_i :

$A_i X_i = B_i$, if `trans=mkl::transpose::nontrans`

$A_i^T X_i = B_i$, if `trans=mkl::transpose::trans`

$A_i^H X_i = B_i$, if `trans=mkl::transpose::conjtrans`

Before calling this routine, the Strided API of the *getrf_batch* function should be called to compute the LU factorizations of A_i .

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event getrs_batch(cl::sycl::queue &queue, mkl::transpose trans, std::int64_t n,
    ↪ std::int64_t nrhs, T *a, std::int64_t lda, std::int64_t stride_a, std::int64_t
    ↪ *ipiv, std::int64_t stride_ipiv, T *b, std::int64_t ldb, std::int64_t stride_b,
    ↪ std::int64_t batch_size, T *scratchpad, std::int64_t scratchpad_size, const std::vector
    ↪ <cl::sycl::event> &events = {})
};
```

Input Parameters

queue Device queue where calculations will be performed.

trans

Form of the equations:

If `trans = mkl::transpose::nontrans`, then $A_i X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::trans`, then $A_i^T X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::conjtrans`, then $A_i^H X_i = B_i$ is solved for X_i .

n Order of the matrices A_i and the number of rows in matrices B_i ($0 \leq n$).

nrhs Number of right-hand sides ($0 \leq nrhs$).

a Array containing the factorizations of the matrices A_i , as returned by the Strided API of the `ref:oneapi::mkl::lapack::getrf_batch_usm` function.

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array `a`.

ipiv `ipiv` array, as returned by `getrf_batch` (USM) function.

stride_ipiv Stride between the beginnings of arrays $ipiv_i$ inside the array `ipiv`.

b Array containing the matrices B_i whose columns are the right-hand sides for the systems of equations.

ldb Leading dimensions of B_i .

stride_b Stride between the beginnings of matrices B_i inside the batch array `b`.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by the Strided API of the `getrs_batch_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

b Solution matrices X_i .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is zero, then diagonal element of some of U_i is zero, and the solve could not be completed. The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The indices of first zero diagonal elements in these U_i matrices can be obtained by `exceptions()` method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

gets_batch_scratchpad_size

Computes size of scratchpad memory required for the *gets_batch* function.

Description

`gets_batch_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Group API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the *gets_batch* function.

Syntax

```

namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t getrs_batch_scratchpad_size(cl::sycl::queue &queue, mkl::transpose *trans,
        ↪ std::int64_t *n, std::int64_t *nrhs, std::int64_t *lda, std::int64_t *ldb, std::int64_t
        ↪ *group_count, std::int64_t *group_sizes)
}

```

Input Parameters

queue Device queue where calculations will be performed.

trans

Array of `group_count` parameters $trans_g$ indicating the form of the equations for the group g :

If `trans = mkl::transpose::nontrans`, then $A_i X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::trans`, then $A_i^T X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::conjtrans`, then $A_i H X_i = B_i$ is solved for X_i .

n Array of `group_count` parameters n_g specifying the order of the matrices A_i and the number of rows in matrices B_i ($0 \leq n_g$) belonging to group g .

nrhs Array of `group_count` parameters $nrhs_g$ specifying the number of right-hand sides ($0 \leq nrhs_g$) for group g .

lda Array of `group_count` parameters lda_g specifying the leading dimensions of A_i from group g .

ldb Array of `group_count` parameters ldb_g specifying the leading dimensions of B_i in the group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the `getrs_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Strided API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the `getrs_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t getrs_batch_scratchpad_size(cl::sycl::queue &queue, mkl::transpose trans,
        ↪std::int64_t n, std::int64_t nrhs, std::int64_t lda, std::int64_t stride_a, std::int64_t
        ↪t stride_ipiv, std::int64_t ldb, std::int64_t stride_b, std::int64_t batch_size)
};
```

Input Parameters

queue Device queue where calculations will be performed.

trans

Indicates the form of the equations:

If `trans = mkl::transpose::nontrans`, then $A_i X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::trans`, then $A_i^T X_i = B_i$ is solved for X_i .

If `trans = mkl::transpose::conjtrans`, then $A_i^H X_i = B_i$ is solved for X_i .

n Order of the matrices A_i and the number of rows in matrices B_i ($0 \leq n$).

nrhs Number of right-hand sides ($0 \leq nrhs$).

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch array `a`.

stride_ipiv Stride between the beginnings of arrays $ipiv_i$ inside the array `ipiv`.

ldb Leading dimension of B_i .

stride_b Stride between the beginnings of matrices B_i inside the batch array `b`.

batch_size Number of problems in a batch.

Return Values

Number of elements of type `T` the scratchpad memory should be able to hold to be passed to the Strided API of the `getrs_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

orgqr_batch

Generates the orthogonal/unitary matrix Q_i of the QR factorizations for a group of general matrices.

Description

orgqr_batch supports the following precisions.

T
float
double

orgqr_batch (Buffer Version)

Description

The buffer version of orgqr_batch supports only the strided API.

Strided API

The routine generates the wholes or parts of $m \times n$ orthogonal matrices Q_i of the batch of QR factorizations formed by the Strided API of the *geqrf_batch (Buffer Version)* function.

Usually Q_i is determined from the QR factorization of an $m \times p$ matrix A_i with $m \geq p$.

To compute the whole matrices Q_i , use:

```
orgqr_batch(queue, m, m, p, a, ...)
```

To compute the leading p columns of Q_i (which form an orthonormal basis in the space spanned by the columns of A_i):

```
orgqr_batch(queue, m, p, p, a, ...)
```

To compute the matrices Q_i^k of the QR factorizations of leading k columns of the matrices A_i :

```
orgqr_batch(queue, m, m, k, a, ...)
```

To compute the leading k columns of Q_i^k (which form an orthonormal basis in the space spanned by leading k columns of the matrices A_i):

```
orgqr_batch(queue, m, k, k, a, ...)
```

Syntax

```
namespace oneapi::mkl::lapack {
    void orgqr_batch(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, std::int64_t_
    ↪ k, cl::sycl::buffer<T> &a, std::int64_t lda, std::int64_t stride_a, cl::sycl::buffer<T>
    ↪ &tau, std::int64_t stride_tau, std::int64_t batch_size, cl::sycl::buffer<T> &
    ↪ scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in the matrices A_i ($0 \leq m$).

n Number of columns in the matrices A_i ($0 \leq n \leq m$).

k Number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k \leq n$).

a Array resulting after call to the Strided API of the *geqrf_batch (Buffer Version)* function.

lda Leading dimension of A_i ($lda \leq m$).

stride_a The stride between the beginnings of matrices A_i inside the batch array **a**.

tau Array resulting from call to the Strided API of the *geqrf_batch (Buffer Version)* function.

stride_tau Stride between the beginnings of arrays τ_i inside the array **tau**.

batch_size Specifies the number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the *orgqr_batch_scratchpad_size* function.

Output Parameters

a Batch of n leading columns of the $m \times m$ orthogonal matrices Q_i .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The **info** code of the problem can be obtained by *info()* method of exception object:

If **info** = **-n**, the n -th parameter had an illegal value.

If **info** equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by *detail()* method of exception object.

If **info** is not zero and *detail()* returns zero, then there were some errors for some of the problems in the supplied batch and **info** code contains the number of failed calculations in a batch.

orgqr_batch (USM Version)

Description

The USM version of `orgqr_batch` supports the group API and strided API.

Group API

The routine generates the wholes or parts of $m \times n$ orthogonal matrices Q_i of the batch of QR factorizations formed by the Group API of the *geqrf_batch (USM Version)* function.

Usually Q_i is determined from the QR factorization of an $m \times p$ matrix A_i with $m \geq p$.

To compute the whole matrices Q_i , use:

```
orgqr_batch(queue, m, m, p, a, ...)
```

To compute the leading p columns of Q_i (which form an orthonormal basis in the space spanned by the columns of A_i):

```
orgqr_batch(queue, m, p, p, a, ...)
```

To compute the matrices Q_i^k of the QR factorizations of leading k columns of the matrices A_i :

```
orgqr_batch(queue, m, m, k, a, ...)
```

To compute the leading k columns of Q_i^k (which form an orthonormal basis in the space spanned by leading k columns of the matrices A_i):

```
orgqr_batch(queue, m, k, k, a, ...)
```

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event orgqr_batch(cl::sycl::queue &queue, std::int64_t *m, std::int64_t *n,
    ↪ std::int64_t *k, T **a, std::int64_t *lda, T **tau, std::int64_t group_count,
    ↪ std::int64_t *group_sizes, T *scratchpad, std::int64_t scratchpad_size, const
    ↪ std::vector<cl::sycl::event> &events = {})
}

```

Input Parameters

queue Device queue where calculations will be performed.

m Array of `group_count` m_g parameters as previously supplied to group version of `geqrf_batch` function.

n Array of `group_count` n_g parameters as previously supplied to group version of `geqrf_batch` function.

k Array of `group_count` k_g parameters as previously supplied to the Group API of the *geqrf_batch (USM Version)* function. The number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k_g \leq n_g$).

a Array resulting after call to the Group API of the *geqrf_batch (USM Version)* function.

lda Array of leading dimensions of A_i as previously supplied to the Group API of the *geqrf_batch (USM Version)* function.

tau Array resulting after call to the Group API of the *geqrf_batch (USM Version)* function.

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by Group API of the *orgqr_batch_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a n_g leading columns of the $m_g \times m_g$ orthogonal matrices Q_i , where g is an index of group of parameters corresponding to Q_i .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The **info** code of the problem can be obtained by *info()* method of exception object:

If **info** = - n , the n -th parameter had an illegal value.

If **info** equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by *detail()* method of exception object.

If **info** is not zero and *detail()* returns zero, then there were some errors for some of the problems in the supplied batch and **info** code contains the number of failed calculations in a batch.

Strided API

The routine generates the wholes or parts of $m \times n$ orthogonal matrices Q_i of the batch of QR factorizations formed by the Strided API of the *geqrf_batch (USM Version)* function.

Usually Q_i is determined from the QR factorization of an $m \times p$ matrix A_i with $m \geq p$.

To compute the whole matrices Q_i , use:

```
orgqr_batch(queue, m, m, p, a, ...)
```

To compute the leading p columns of Q_i (which form an orthonormal basis in the space spanned by the columns of A_i):

```
orgqr_batch(queue, m, p, p, a, ...)
```

To compute the matrices Q_i^k of the QR factorizations of leading k columns of the matrices A_i :

```
orgqr_batch(queue, m, m, k, a, ...)
```

To compute the leading k columns of Q_i^k (which form an orthonormal basis in the space spanned by leading k columns of the matrices A_i):

```
orgqr_batch(queue, m, k, k, a, ...)
```

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event orgqr_batch(cl::sycl::queue &queue, std::int64_t m, std::int64_t n,
    ↪ std::int64_t k, T *a, std::int64_t lda, std::int64_t stride_a, T *tau, std::int64_t
    ↪ stride_tau, std::int64_t batch_size, T *scratchpad, std::int64_t scratchpad_size,
    ↪ const std::vector<cl::sycl::event> &events = {})
};
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in the matrices A_i ($0 \leq m$).

n Number of columns in the matrices A_i ($0 \leq n \leq m$).

k Number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k \leq n$).

a Array resulting after call to the Strided API of the *geqrf_batch (USM Version)* function.

lda Leading dimension of A_i ($lda \leq m$).

stride_a The stride between the beginnings of matrices A_i inside the batch array **a**.

tau Array resulting from call to the Strided API of the *geqrf_batch (USM Version)* function.

stride_tau Stride between the beginnings of arrays τ_i inside the array **tau**.

batch_size Specifies the number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the *orgqr_batch_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Batch of n leading columns of the $m \times m$ orthogonal matrices Q_i .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The *info* code of the problem can be obtained by *info()* method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as `scratchpad_size`, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

Parent topic: *LAPACK-like Extensions Routines*

orgqr_batch_scratchpad_size

Computes size of scratchpad memory required for the *orgqr_batch* function.

Description

`orgqr_batch_scratchpad_size` supports the following precisions.

T
float
double

Group API

Computes the number of elements of type T the scratchpad memory should able to hold to be passed to the Group API of the *orgqr_batch* function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t orgqr_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t *m,
        ↪ std::int64_t *n, std::int64_t *k, std::int64_t *lda, std::int64_t group_count,
        ↪ std::int64_t *group_sizes)
}

```

Input Parameters

queue Device queue where calculations will be performed.

m Array of `group_count` m_g parameters.

n Array of `group_count` n_g parameters.

k Array of `group_count` k_g parameters. The number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k_g \leq n_g$).

lda Array of leading dimensions of A_i .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the *orgqr_batch* function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Strided API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the *orgqr_batch* function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t orgqr_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t m,
        ↪ std::int64_t n, std::int64_t k, std::int64_t lda, std::int64_t stride_a, std::int64_t
        ↪ stride_tau, std::int64_t batch_size)
};
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in the matrices A_i ($0 \leq m$).

n Number of columns in the matrices A_i ($0 \leq n$).

k Number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k \leq n$).

lda Leading dimension of A_i ($lda \leq m$).

stride_a Stride between the beginnings of matrices A_i inside the batch array a.

stride_tau Stride between the beginnings of arrays τ_i inside the array tau.

batch_size Number of problems in a batch.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the `orgqr_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

potrf_batch

Computes the LU factorizations of a batch of general matrices.

Description

`potrf_batch` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

potrf_batch (Buffer Version)

Description

The buffer version of `potrf_batch` supports only the strided API.

Strided API

The routine forms the Cholesky factorizations of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrices A_i , $i \in \{1..batch_size\}$:

$A_i = U_i^T U_i$ for real data, $A_i = U_i^H U_i$ for complex data if `uplo = mkl::uplo::upper`,

$A_i = L_i L_i^T$ for real data, $A_i = L_i L_i^H$ for complex data if `uplo = mkl::uplo::lower`,

where L_i is a lower triangular matrix and U_i is upper triangular.

Syntax

```
namespace oneapi::mkl::lapack {
    void potrf_batch(cl::sycl::queue &queue, mkl::uplo uplo, std::int64_t n,
    ↪ cl::sycl::buffer<T> &a, std::int64_t lda, std::int64_t stride_a, std::int64_t batch_
    ↪ size, cl::sycl::buffer<T> &scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Indicates whether the upper or lower triangular part of A_i is stored and how A_i is factored:

If `uplo = mkl::uplo::upper`, the array `a` stores the upper triangular parts of the matrices A_i ,

If `uplo = mkl::uplo::lower`, the array `a` stores the lower triangular parts of the matrices A_i .

n Order of the matrices A_i , ($0 \leq n$).

a Array containing batch of input matrices A_i , each of A_i being of size $lda \cdot n$ and holding either upper or lower triangular parts of the matrices A_i (see `uplo`).

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by the Strided API of the `potrf_batch_scratchpad_size` function.

Output Parameters

a Cholesky factors U_i or L_i , as specified by `uplo`.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as `scratchpad_size`, and `detail()` returns non zero, then passed `scratchpad` is of insufficient size, and required size should be not less than value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is zero, then the leading minors of some of matrices (and therefore some matrices A_i themselves) are not positive-definite, and the factorizations could not be completed for these matrices from the batch. The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The orders of corresponding not positive-definite leading minors of these matrices can be obtained by `exceptions()` method of exception object.

potrf_batch (USM Version)

Description

The USM version of `potrf_batch` supports the group API and strided API.

Group API

The routine forms the Cholesky factorizations of symmetric positive-definite or, for complex data, Hermitian positive-definite matrices $A_i, i \in \{1 \dots batch_size\}$:

$A_i = U_i^T U_i$ for real data ($A_i = U_i^H U_i$ for complex), if `uplog` is `mkl::uplo::upper`,

$A_i = L_i L_i^T$ for real data ($A_i = L_i L_i^H$ for complex), if `uplog` is `mkl::uplo::lower`,

where L_i is a lower triangular matrix and U_i is upper triangular, g is an index of group of parameters corresponding to A_i , and total number of problems to solve, `batch_size`, is a sum of sizes of all of the groups of parameters as provided by `group_sizes` array

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event potrf_batch(cl::sycl::queue &queue, mkl::uplo *uplo, std::int64_t *n,
    ↪ T **a, std::int64_t *lda, std::int64_t group_count, std::int64_t *group_sizes, T
    ↪ *scratchpad, std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events,
    ↪ = {})
}
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Array of `group_count` `uplog` parameters. Each `uplog` indicates whether the upper or lower triangular parts of the input matrices are provided:

If `uplog` is `mkl::uplo::upper`, input matrices from array `a` belonging to group g store the upper triangular parts,

If `uplog` is `mkl::uplo::lower`, input matrices from array `a` belonging to group g store the lower triangular parts.

n Array of `group_count` n_g parameters. Each n_g specifies the order of the input matrices from array `a` belonging to group g .

a Array of `batch_size` pointers to input matrices A_i , each being of size `ldag · ng` (g is an index of group to which A_i belongs to) and holding either upper or lower triangular part as specified by `uplog`.

lda Array of `group_count` lda_g parameters. Each lda_g specifies the leading dimensions of the matrices from a belonging to group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Group API of the `potrf_batch_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Cholesky factors U_i or L_i , as specified by $uplo_g$ from corresponding group of parameters.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is zero, then the leading minors of some of the input matrices (and therefore some matrices themselves) are not positive-definite, and the factorizations could not be completed for these matrices from the batch. The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The orders of corresponding not positive-definite leading minors of these matrices can be obtained by `exceptions()` method of the exception object.

Strided API

The routine forms the Cholesky factorizations of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrices A_i , $i \in \{1 \dots batch_size\}$:

$A_i = U_i^T U_i$ for real data, $A_i = U_i^H U_i$ for complex data if `uplo = mkl::uplo::upper`,

$A_i = L_i L_i^T$ for real data, $A_i = L_i L_i^H$ for complex data if `uplo = mkl::uplo::lower`,

where L_i is a lower triangular matrix and U_i is upper triangular.

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event potrf_batch(cl::sycl::queue &queue, mkl::uplo uplo, std::int64_t n, T,
    ↪ *a, std::int64_t lda, std::int64_t stride_a, std::int64_t batch_size, T *scratchpad,
    ↪ std::int64_t scratchpad_size, const std::vector<cl::sycl::event> &events = {})
};
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Indicates whether the upper or lower triangular part of A_i is stored and how A_i is factored:

If `uplo = mkl::uplo::upper`, the array `a` stores the upper triangular parts of the matrices A_i ,

If `uplo = mkl::uplo::lower`, the array `a` stores the lower triangular parts of the matrices A_i .

n Order of the matrices A_i , ($0 \leq n$).

a Array containing batch of input matrices A_i , each of A_i being of size `lda · n` and holding either upper or lower triangular parts of the matrices A_i (see `uplo`).

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type `T`. Size should not be less than the value returned by the Strided API of the `potrf_batch_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Cholesky factors U_i or L_i , as specified by `uplo`.

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is zero, then the leading minors of some of matrices (and therefore some matrices A_i themselves) are not positive-definite, and the factorizations could not be completed for these matrices from the batch. The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The orders of corresponding not positive-definite leading minors of these matrices can be obtained by `exceptions()` method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

potrf_batch_scratchpad_size

Computes size of scratchpad memory required for the `potrf_batch` function.

Description

`potrf_batch_scratchpad_size` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Group API

Computes the number of elements of type T the scratchpad memory should able to hold to be passed to the Group API of the `potrf_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t potrf_batch_scratchpad_size(cl::sycl::queue &queue, mkl::uplo *uplo,
        ↪ std::int64_t *n, std::int64_t *lda, std::int64_t group_count, std::int64_t *group_
        ↪ sizes)
}
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Array of `group_count` $uplo_g$ parameters.

Each of $uplo_g$ indicates whether the upper or lower triangular parts of the input matrices are provided:

If $uplo_g$ is `mk1::uplo::upper`, input matrices from array `a` belonging to group g store the upper triangular parts,

If $uplo_g$ is `mk1::uplo::lower`, input matrices from array `a` belonging to group g store the lower triangular parts.

n

Array of `group_count` n_g parameters.

Each n_g specifies the order of the input matrices belonging to group g .

lda

Array of `group_count` lda_g parameters.

Each lda_g specifies the leading dimensions of the matrices belonging to group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the `potrf_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Strided API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the `potrf_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t potrf_batch_scratchpad_size(cl::sycl::queue &queue, mkl::uplo uplo,
        ↪std::int64_t n, std::int64_t lda, std::int64_t stride_a, std::int64_t batch_size)
};
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Indicates whether the upper or lower triangular part of A_i is stored and how A_i is factored:

If `uplo = mkl::uplo::upper`, the array `a` stores the upper triangular parts of the matrices A_i ,

If `uplo = mkl::uplo::lower`, the array `a` stores the lower triangular parts of the matrices A_i .

n Order of the matrices A_i , ($0 \leq n$).

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices A_i inside the batch.

batch_size Number of problems in a batch.

Return Values

Number of elements of type `T` the scratchpad memory should be able to hold to be passed to the Strided API of the `potrf_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

potrs_batch

Computes the LU factorizations of a batch of general matrices.

Description

potrs_batch supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

potrs_batch (Buffer Version)

Description

The buffer version of potrs_batch supports only the strided API.

Strided API

The routine solves for X_i the systems of linear equations $A_i X_i = B_i$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrices A_i , given the Cholesky factorization of A_i , $i \in \{1 \dots batch_size\}$:

$A_i = U_i^T U_i$ for real data, $A_i = U_i^H U_i$ for complex data if `uplo = mkl::uplo::upper`,

$A_i = L_i L_i^T$ for real data, $A_i = L_i L_i^H$ for complex data if `uplo = mkl::uplo::lower`,

where L_i is a lower triangular matrix and U_i is upper triangular.

The systems are solved with multiple right-hand sides stored in the columns of the matrices B_i .

Before calling this routine, matrices A_i should be factorized by call to the Strided API of the *potrf_batch (Buffer Version)* function.

Syntax

```

namespace oneapi::mkl::lapack {
    void potrs_batch(cl::sycl::queue &queue, mkl::uplo uplo, std::int64_t n, std::int64_t,
    ↪ nrhs, cl::sycl::buffer<T> &a, std::int64_t lda, std::int64_t stride_a, cl::sycl::buffer
    ↪ <T> &b, std::int64_t ldb, std::int64_t stride_b, std::int64_t batch_size,
    ↪ cl::sycl::buffer<T> &scratchpad, std::int64_t scratchpad_size)
}

```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Indicates how the input matrices have been factored:

If `uplo = mkl::uplo::upper`, the upper triangle U_i of A_i is stored, where $A_i = U_i^T U_i$ for real data, $A_i = U_i^H U_i$ for complex data.

If `uplo = mkl::uplo::lower`, the upper triangle L_i of A_i is stored, where $A_i = L_i L_i^T$ for real data, $A_i = L_i L_i^H$ for complex data.

n The order of matrices A_i ($0 \leq n$).

nrhs The number of right-hand sides ($0 \leq nrhs$).

a Array containing batch of factorizations of the matrices A_i , as returned by the Strided API of the *potrf_batch (Buffer Version)* function.

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices inside the batch array **a**.

b Array containing batch of matrices B_i whose columns are the right-hand sides for the systems of equations.

ldb Leading dimension of B_i .

stride_b Stride between the beginnings of matrices B_i inside the batch array **b**.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the *potrs_batch_scratchpad_size* function.

Output Parameters

b Solution matrices X_i .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by *info()* method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by *detail()* method of exception object.

If `info` is not zero and *detail()* returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is zero, then for some of the matrices diagonal element of the Cholesky factor is zero, and the solve could not be completed. The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The indices of first zero diagonal elements in these matrices can be obtained by `exceptions()` method of exception object.

potrs_batch (USM Version)

Description

The USM version of `potrs_batch` supports the group API and strided API.

Group API

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event potrs_batch(cl::sycl::queue &queue, mkl::uplo *uplo, std::int64_t *n,
    ↪ std::int64_t *nrhs, T **a, std::int64_t *lda, T **b, std::int64_t *ldb, std::int64_t
    ↪ group_count, std::int64_t *group_sizes, T *scratchpad, std::int64_t scratchpad_size,
    ↪ const std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Array of `group_count` $uplo_g$ parameters.

Each of $uplo_g$ indicates whether the upper or lower triangular parts of the input matrices are provided:

If $uplo_g$ is `mkl::uplo::upper`, input matrices from array `a` belonging to group g store the upper triangular parts,

If $uplo_g$ is `mkl::uplo::lower`, input matrices from array `a` belonging to group g store the lower triangular parts.

n

Array of `group_count` n_g parameters.

Each n_g specifies the order of the input matrices from array `a` belonging to group g .

nrhs

Array of `group_count` $nrhs_g$ parameters.

Each $nrhs_g$ specifies the number of right-hand sides supplied for group g in corresponding part of array `b`.

a Array of `batch_size` pointers to Cholesky factored matrices A_i as returned by the Group API of the `potrf_batch` (USM Version) function.

lda

Array of `group_count` lda_g parameters.

Each lda_g specifies the leading dimensions of the matrices from `a` belonging to group g .

b Array of `batch_size` pointers to right-hand side matrices B_i , each of size $ldb_g \cdot nrhs_g$, where g is an index of group corresponding to B_i .

ldb

Array of `group_count` ldb_g parameters.

Each ldb_g specifies the leading dimensions of the matrices from `b` belonging to group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Group API of the `potrs_batch_scratchpad_size` function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

b Solution matrices X_i .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::lapack::batch_error`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info` = `-n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

If `info` is zero, then for some of the matrices diagonal element of the Cholesky factor is zero, and the solve could not be completed. The indices of such matrices in the batch can be obtained with `ids()` method of the exception object. The indices of first zero diagonal elements in these matrices can be obtained by `exceptions()` method of exception object.

Strided API

The routine solves for X_i the systems of linear equations $A_i X_i = B_i$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrices A_i , given the Cholesky factorization of A_i , $i \in \{1 \dots batch_size\}$:

$A_i = U_i^T U_i$ for real data, $A_i = U_i^H U_i$ for complex data if `uplo` = `mkl::uplo::upper`,

$A_i = L_i L_i^T$ for real data, $A_i = L_i L_i^H$ for complex data if `uplo = mkl::uplo::lower`, where L_i is a lower triangular matrix and U_i is upper triangular.

The systems are solved with multiple right-hand sides stored in the columns of the matrices B_i .

Before calling this routine, matrices A_i should be factorized by call to the Strided API of the *potrf_batch (USM Version)* function.

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event potrs_batch(cl::sycl::queue &queue, mkl::uplo uplo, std::int64_t n,
    ↪ std::int64_t nrhs, T *a, std::int64_t lda, std::int64_t stride_a, T *b, std::int64_t
    ↪ ldb, std::int64_t stride_b, std::int64_t batch_size, T *scratchpad, std::int64_t
    ↪ scratchpad_size, const std::vector<cl::sycl::event> &events = {})
};
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Indicates how the input matrices have been factored:

If `uplo = mkl::uplo::upper`, the upper triangle U_i of A_i is stored, where $A_i = U_i^T U_i$ for real data, $A_i = U_i^H U_i$ for complex data.

If `uplo = mkl::uplo::lower`, the upper triangle L_i of A_i is stored, where $A_i = L_i L_i^T$ for real data, $A_i = L_i L_i^H$ for complex data.

n The order of matrices A_i ($0 \leq n$).

nrhs The number of right-hand sides ($0 \leq nrhs$).

a Array containing batch of factorizations of the matrices A_i , as returned by the Strided API of the *potrf_batch (USM Version)* function.

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices inside the batch array a.

b Array containing batch of matrices B_i whose columns are the right-hand sides for the systems of equations.

ldb Leading dimension of B_i .

stride_b Stride between the beginnings of matrices B_i inside the batch array b.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by the Strided API of the *potrs_batch_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

b Solution matrices X_i .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of problems during calculations. The info code of the problem can be obtained by *info()* method of exception object:

If *info* = *-n*, the *n*-th parameter had an illegal value.

If *info* equals to value passed as scratchpad size, and *detail()* returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by *detail()* method of exception object.

If *info* is not zero and *detail()* returns zero, then there were some errors for some of the problems in the supplied batch and *info* code contains the number of failed calculations in a batch.

If *info* is zero, then for some of the matrices diagonal element of the Cholesky factor is zero, and the solve could not be completed. The indices of such matrices in the batch can be obtained with *ids()* method of the exception object. The indices of first zero diagonal elements in these matrices can be obtained by *exceptions()* method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

potrs_batch_scratchpad_size

Computes size of scratchpad memory required for the *potrs_batch* function.

Description

potrs_batch_scratchpad_size supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Group API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the `potrs_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t potrs_batch_scratchpad_size(cl::sycl::queue &queue, mkl::uplo *uplo,
        ↪ std::int64_t *n, std::int64_t *nrhs, std::int64_t *lda, std::int64_t *ldb, std::int64_t
        ↪ *group_count, std::int64_t *group_sizes)
}
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Array of `group_count` $uplo_g$ parameters.

Each of $uplo_g$ indicates whether the upper or lower triangular parts of the input matrices are provided:

If $uplo_g$ is `mkl::uplo::upper`, input matrices from array `a` belonging to group g store the upper triangular parts,

If $uplo_g$ is `mkl::uplo::lower`, input matrices from array `a` belonging to group g store the lower triangular parts.

n

Array of `group_count` n_g parameters.

Each n_g specifies the order of the input matrices belonging to group g .

nrhs

Array of `group_count` $nrhs_g$ parameters.

Each $nrhs_g$ specifies the number of right-hand sides supplied for group g .

lda

Array of `group_count` lda_g parameters.

Each lda_g specifies the leading dimensions of the matrices belonging to group g .

ldb

Array of `group_count` ldb_g parameters.

Each ldb_g specifies the leading dimensions of the matrices belonging to group g .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the *potrs_batch* function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Strided API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the *potrs_batch* function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t potrs_batch_scratchpad_size(cl::sycl::queue &queue, mkl::uplo uplo,
        ↪ std::int64_t n, std::int64_t nrhs, std::int64_t lda, std::int64_t stride_a, std::int64_t
        ↪ t ldb, std::int64_t stride_b, std::int64_t batch_size)
};
```

Input Parameters

queue Device queue where calculations will be performed.

uplo

Indicates how the input matrices have been factored:

If `uplo = mkl::uplo::upper`, the upper triangle U_i of A_i is stored, where $A_i = U_i^T U_i$ for real data, $A_i = U_i^H U_i$ for complex data.

If `uplo = mkl::uplo::lower`, the upper triangle L_i of A_i is stored, where $A_i = L_i L_i^T$ for real data, $A_i = L_i L_i^H$ for complex data.

n Order of matrices A_i ($0 \leq n$).

nrhs Number of right-hand sides ($0 \leq nrhs$).

lda Leading dimension of A_i .

stride_a Stride between the beginnings of matrices inside the batch array a.

ldb Leading dimensions of B_i .

stride_b Stride between the beginnings of matrices B_i inside the batch array b.

batch_size Number of problems in a batch.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the `potrs_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

ungqr_batch

Generates the complex unitary matrices Q_i of the batch of QR factorizations formed by the `geqrf_batch` function.

Description

`ungqr_batch` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

ungqr_batch (Buffer Version)

Description

The buffer version of `ungqr_batch` supports only the strided API.

Strided API

The routine generates the wholes or parts of m times m unitary matrices Q_i of the batch of QR factorization formed by the Strided API of the `geqrf_batch (Buffer Version)`.

Usually Q_i is determined from the QR factorization of an $m \times p$ matrix A_i with $m \geq p$.

To compute the whole matrices Q_i , use:

```
ungqr_batch(queue, m, m, p, a, ...)
```

To compute the leading p columns of Q_i (which form an orthonormal basis in the space spanned by the columns of A_i):

```
ungqr_batch(queue, m, p, p, a, ...)
```

To compute the matrices Q_i of the QR factorizations of leading k columns of the matrices A_i :

```
ungqr_batch(queue, m, m, k, a, ...)
```

To compute the leading k columns of Q_i^k (which form an orthonormal basis in the space spanned by leading k columns of the matrices A_i):

```
ungqr_batch(queue, m, k, k, a, ...)
```

Syntax

```
namespace oneapi::mkl::lapack {
    void ungqr_batch(cl::sycl::queue &queue, std::int64_t m, std::int64_t n, std::int64_t,
    ↪ k, cl::sycl::buffer<T> &a, std::int64_t lda, std::int64_t stride_a, cl::sycl::buffer<T>
    ↪ &tau, std::int64_t stride_tau, std::int64_t batch_size, cl::sycl::buffer<T> &
    ↪ scratchpad, std::int64_t scratchpad_size)
}
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in the matrices A_i ($0 \leq m$).

n Number of columns in the matrices A_i ($0 \leq n$).

k Number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k \leq n$).

a Array resulting after call to the Strided API of the *geqrf_batch (USM Version)* function.

lda Leading dimension of A_i ($lda \leq m$).

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

tau Array resulting after call to the Strided API of the *geqrf_batch (USM Version)* function.

stride_tau Stride between the beginnings of arrays τ_i inside the array **tau**.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by strided version of the Strided API of the *ungqr_batch_scratchpad_size* function.

Output Parameters

a Array data is overwritten by a batch of n leading columns of the $m \times m$ unitary matrices Q_i .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of problems during calculations. The info code of the problem can be obtained by info() method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

ungqr_batch (USM Version)

Description

The USM version of `ungqr_batch` supports the group API and strided API.

Group API

The routine generates the wholes or parts of m times m unitary matrices Q_i of the batch of QR factorization formed by the Group API of the `geqrf_batch (Buffer Version)`.

Usually Q_i is determined from the QR factorization of an $m \times p$ matrix A_i with $m \geq p$.

To compute the whole matrices Q_i , use:

```
ungqr_batch(queue, m, m, p, a, ...)
```

To compute the leading p columns of Q_i (which form an orthonormal basis in the space spanned by the columns of A_i):

```
ungqr_batch(queue, m, p, p, a, ...)
```

To compute the matrices Q_i of the QR factorizations of leading k columns of the matrices A_i :

```
ungqr_batch(queue, m, m, k, a, ...)
```

To compute the leading k columns of Q_i^k (which form an orthonormal basis in the space spanned by leading k columns of the matrices A_i):

```
ungqr_batch(queue, m, k, k, a, ...)
```

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event ungqr_batch(cl::sycl::queue &queue, std::int64_t *m, std::int64_t *n,
    ↪ std::int64_t *k, T **a, std::int64_t *lda, T **tau, std::int64_t group_count,
    ↪ std::int64_t *group_sizes, T *scratchpad, std::int64_t scratchpad_size, const
    ↪ std::vector<cl::sycl::event> &events = {})
}
```

Input Parameters

queue Device queue where calculations will be performed.

m Array of `group_count` m_g parameters as previously supplied to the Group API of the `geqrf_batch (USM Version)` function.

n Array of `group_count` n_g parameters as previously supplied to the Group API of the `geqrf_batch (USM Version)` function.

k

Array of `group_count` k_g parameters as previously supplied to the Group API of the `geqrf_batch (USM Version)` function.

The number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k_g \leq n_g$).

- a** Array resulting after call to the Group API of the `geqrf_batch (USM Version)` function.
- lda** Array of leading dimensions of A_i as previously supplied to the Group API of the `geqrf_batch (USM Version)` function.
- tau** Array resulting after call to the Group API of the `geqrf_batch (USM Version)` function.
- group_count** Number of groups of parameters. Must be at least 0.
- group_sizes** Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.
- scratchpad** Scratchpad memory to be used by routine for storing intermediate results.
- scratchpad_size** Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by Group API of the `ungqr_batch_scratchpad_size` function.
- events** List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

- a** Matrices pointed to by array `a` are overwritten by n_g leading columns of the $m_g \times m_g$ orthogonal matrices Q_i , where g is an index of group of parameters corresponding to Q_i .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

`oneapi::mkl::lapack::batch_error`

`oneapi::mkl::unimplemented`

`oneapi::mkl::unsupported_device`

`oneapi::mkl::lapack::invalid_argument`

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value. If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less than value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

Strided API

The routine generates the wholes or parts of m times m unitary matrices Q_i of the batch of QR factorization formed by the Strided API of the `geqrf_batch (USM Version)`.

Usually Q_i is determined from the QR factorization of an $m \times p$ matrix A_i with $m \geq p$.

To compute the whole matrices Q_i , use:

```
ungqr_batch(queue, m, m, p, a, ...)
```

To compute the leading p columns of Q_i (which form an orthonormal basis in the space spanned by the columns of A_i):

```
ungqr_batch(queue, m, p, p, a, ...)
```

To compute the matrices Q_i of the QR factorizations of leading k columns of the matrices A_i :

```
ungqr_batch(queue, m, m, k, a, ...)
```

To compute the leading k columns of Q_i^k (which form an orthonormal basis in the space spanned by leading k columns of the matrices A_i):

```
ungqr_batch(queue, m, k, k, a, ...)
```

Syntax

```
namespace oneapi::mkl::lapack {
    cl::sycl::event ungqr_batch(cl::sycl::queue &queue, std::int64_t m, std::int64_t n,
    ↪ std::int64_t k, T *a, std::int64_t lda, std::int64_t stride_a, T *tau, std::int64_t
    ↪ stride_tau, std::int64_t batch_size, T *scratchpad, std::int64_t scratchpad_size,
    ↪ const std::vector<cl::sycl::event> &events = {})
};
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in the matrices A_i ($0 \leq m$).

n Number of columns in the matrices A_i ($0 \leq n$).

k Number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k \leq n$).

a Array resulting after call to the Strided API of the *geqrf_batch (USM Version)* function.

lda Leading dimension of A_i ($lda \leq m$).

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

tau Array resulting after call to the Strided API of the *geqrf_batch (USM Version)* function.

stride_tau Stride between the beginnings of arrays τ_i inside the array **tau**.

batch_size Number of problems in a batch.

scratchpad Scratchpad memory to be used by routine for storing intermediate results.

scratchpad_size Size of scratchpad memory as a number of floating point elements of type T. Size should not be less than the value returned by strided version of the Strided API of the *ungqr_batch_scratchpad_size* function.

events List of events to wait for before starting computation. Defaults to empty list.

Output Parameters

a Array data is overwritten by a batch of n leading columns of the $m \times m$ unitary matrices Q_i .

Return Values

Output event to wait on to ensure computation is complete.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::lapack::batch_error

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

The `info` code of the problem can be obtained by `info()` method of exception object:

If `info = -n`, the n -th parameter had an illegal value.

If `info` equals to value passed as scratchpad size, and `detail()` returns non zero, then passed scratchpad is of insufficient size, and required size should be not less then value returned by `detail()` method of exception object.

If `info` is not zero and `detail()` returns zero, then there were some errors for some of the problems in the supplied batch and `info` code contains the number of failed calculations in a batch.

Parent topic: *LAPACK-like Extensions Routines*

ungqr_batch_scratchpad_size

Computes size of scratchpad memory required for the *ungqr_batch* function.

Description

`ungqr_batch_scratchpad_size` supports the following precisions.

T
<code>std::complex<float></code>
<code>std::complex<double></code>

Group API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the *ungqr_batch* function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t ungqr_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t *m,
        ↪ std::int64_t *n, std::int64_t *k, std::int64_t *lda, std::int64_t group_count,
        ↪ std::int64_t *group_sizes)
    }
}
```

Input Parameters

queue Device queue where calculations will be performed.

m Array of `group_count` m_g parameters.

n Array of `group_count` n_g parameters.

k

Array of `group_count` k_g parameters.

Number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k_g \leq n_g$).

lda Array of leading dimensions of A_i .

group_count Number of groups of parameters. Must be at least 0.

group_sizes Array of `group_count` integers. Array element with index g specifies the number of problems to solve for each of the groups of parameters g . So the total number of problems to solve, `batch_size`, is a sum of all parameter group sizes.

Return Values

Number of elements of type T the scratchpad memory should be able to hold to be passed to the Group API of the `ungqr_batch` function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by `info()` method of exception object.

Strided API

Computes the number of elements of type T the scratchpad memory should be able to hold to be passed to the Strided API of the `ungqr_batch` function.

Syntax

```
namespace oneapi::mkl::lapack {
    template <typename T>
        std::int64_t ungqr_batch_scratchpad_size(cl::sycl::queue &queue, std::int64_t m,
        ↪std::int64_t n, std::int64_t k, std::int64_t lda, std::int64_t stride_a, std::int64_t,
        ↪stride_tau, std::int64_t batch_size)
};
```

Input Parameters

queue Device queue where calculations will be performed.

m Number of rows in the matrices A_i ($0 \leq m$).

n Number of columns in the matrices A_i ($0 \leq n$).

k Number of elementary reflectors whose product defines the matrices Q_i ($0 \leq k \leq n$).

lda Leading dimensions of A_i ($lda \leq m$).

stride_a Stride between the beginnings of matrices A_i inside the batch array **a**.

stride_tau Stride between the beginnings of arrays τ_i inside the array **tau**.

batch_size Number of problems in a batch.

Return Values

Number of elements of type **T** the scratchpad memory should be able to hold to be passed to the Strided API of the *ungqr_batch* function.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::unimplemented

oneapi::mkl::unsupported_device

oneapi::mkl::lapack::invalid_argument

Exception is thrown in case of incorrect supplied argument value. Position of wrong argument can be determined by *info()* method of exception object.

Parent topic: *LAPACK-like Extensions Routines*

Note

Different arrays used as parameters to oneMKL LAPACK routines must not overlap.

Warning

LAPACK routines assume that input matrices do not contain IEEE 754 special values such as INF or NaN values. Using these special values may cause LAPACK to return unexpected results or become unstable.

Parent topic: *Dense Linear Algebra*

11.2.2 Sparse Linear Algebra

The oneAPI Math Kernel Library provides a Data Parallel C++ interface to some of the Sparse Linear Algebra routines.

Sparse BLAS provides basic operations on sparse vectors and matrices, and separates them into two stages: analysis (also called inspector stage or optimize stage) and execution. For a given matrix, the analysis would typically be called one time and the execution may be called multiple times. During the analysis stage, the API inspects the matrix properties including size, sparsity pattern and available parallelism and can apply matrix format or structure changes to enable a more optimized algorithm. In the execution stage, multiple routine calls can take advantage of the analysis stage data in order to improve performance.

In order to save information in between calls to Sparse BLAS computation routines, the *matrix_handle_t* type is introduced, that is essentially an opaque pointer, used to store data related to initial sparse matrix and data obtained during analysis stage.

Sparse BLAS

Sparse BLAS Routines provide basic operations on sparse vectors and matrices

Routines	Description
<i>init_matrix_handle</i>	Initialize the sparse matrix handle
<i>release_matrix_handle</i>	Release the sparse matrix handle
<i>set_csr_data</i>	Fills the internal CSR data structure
<i>optimize_gemv</i>	Optimize routine for gemv
<i>optimize_trmv</i>	Optimize routine for trmv
<i>optimize_trsv</i>	Optimize routine for trsv
<i>gemv</i>	Sparse matrix-dense vector product using a general sparse matrix
<i>gemvdot</i>	Sparse matrix-dense vector product followed by dot product
<i>symv</i>	Sparse matrix-dense vector product using a symmetric sparse matrix
<i>trmv</i>	Sparse matrix-dense vector product using a triangular sparse matrix
<i>trsv</i>	Solving a linear system with a triangular sparse matrix
<i>gemm</i>	Sparse matrix-dense matrix product using a general sparse matrix

- *Sparse storage formats*

init_matrix_handle

Initializes a `matrix_handle_t` object to default values.

Description and Assumptions

The `oneapi::mkl::sparse::init_matrix_handle` function initializes the `matrix_handle_t` object with default values.

Syntax

```
namespace oneapi::mkl::sparse {  
  
    void init_matrix_handle (oneapi::mkl::sparse::matrix_handle_t *handle);  
  
}
```

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::device_bad_alloc
oneapi::mkl::host_bad_alloc
oneapi::mkl::invalid_argument
oneapi::mkl::unimplemented
oneapi::mkl::uninitialized
oneapi::mkl::unsupported_device

Parent topic: *Sparse BLAS*

release_matrix_handle

Releases internal data and sets `matrix_handle_t` object to NULL.

Description and Assumptions

The `oneapi::mkl::sparse::release_matrix_handle` releases any internal data that the `matrix_handle_t` object holds and sets it with defaults values, otherwise it throws an exception. The routine also waits for the dependencies to be finished before releasing any data in case of USM.

Syntax

```

namespace oneapi::mkl::sparse {

    void release_matrix_handle (oneapi::mkl::sparse::matrix_handle_t handle,
                               const std::vector<sycl::event> &dependencies = {});

}

```

Input parameter

handle Handle to object containing sparse matrix and other internal data. Created using one of the `oneapi::mkl::sparse::set_<sparse_matrix_type>_structure` routines.

dependencies List of events that `handle` depends on. The call waits on the events(if any) before resetting the `handle` to default values.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

Parent topic: *Sparse BLAS*

set_csr_data

Takes a matrix handle and the input CSR matrix arrays and fills the internal CSR data structure.

Description and Assumptions

Refer to *Supported Types* for a list of supported `<fp>` and `<intType>`. The `mkl::sparse::set_csr_data` routine takes a matrix handle for a sparse matrix of dimensions `num_rows` -by- `num_cols` represented in the CSR format, and fills the internal CSR data structure.

set_csr_data (Buffer version)

Syntax

```

namespace oneapi::mkl::sparse {

    void set_csr_data (oneapi::mkl::sparse::matrix_handle_t handle,
                      intType num_rows,
                      intType num_cols,
                      oneapi::mkl::index_base index,
                      sycl::buffer<intType, 1> &row_ptr,
                      sycl::buffer<intType, 1> &col_ind,
                      sycl::buffer<fp, 1> &val);

}

```

Input Parameters

handle Handle to object containing sparse matrix and other internal data for subsequent DPC++ Sparse BLAS operations.

num_rows Number of rows of the input matrix .

num_cols Number of columns of the input matrix .

index Indicates how input arrays are indexed. The possible options are described in *index_base* enum class.

row_ptr SYCL memory object containing an array of length `num_rows+1`. Refer to *CSR* format for detailed description of `row_ptr`.

col_ind SYCL memory object which stores an array containing the column indices in `index`-based numbering. Refer to *CSR* format for detailed description of `col_ind`.

val SYCL memory object which stores an array containing non-zero elements of the input matrix. Refer to *CSR* format for detailed description of `val`.

Output Parameters

handle Handle to object containing sparse matrix and other internal data for subsequent SYCL Sparse BLAS operations.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error
oneapi::mkl::device_bad_alloc
oneapi::mkl::host_bad_alloc
oneapi::mkl::invalid_argument
oneapi::mkl::unimplemented
oneapi::mkl::uninitialized

*oneapi::mkl::unsupported_device***set_csr_data (USM version)****Syntax**

```

namespace oneapi::mkl::sparse {

    void set_csr_data (oneapi::mkl::sparse::matrix_handle_t handle,
                      intType                               num_rows,
                      intType                               num_cols,
                      oneapi::mkl::index_base              index,
                      intType                               *row_ptr,
                      intType                               *col_ind,
                      fp                                    *val);

}

```

Input Parameters

handle Handle to object containing sparse matrix and other internal data for subsequent DPC++ Sparse BLAS operations.

num_rows Number of rows of the input matrix .

num_cols Number of columns of the input matrix .

index Indicates how input arrays are indexed. The possible options are described in *index_base* enum class.

row_ptr USM object containing an array of length num_rows+1. Refer to *CSR* format for detailed description of row_ptr

col_ind USM object which stores an array containing the column indices in index-based numbering. Refer to *CSR* format for detailed description of col_ind

val USM object which stores an array containing non-zero elements of the input matrix. Refer to *CSR* format for detailed description of val

Output Parameters

handle Handle to object containing sparse matrix and other internal data for subsequent SYCL Sparse BLAS operations.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

Parent topic: *Sparse BLAS*

gemm

Computes a sparse matrix times dense matrix product.

Description and Assumptions

Refer to *Supported Types* for a list of supported `<fp>` and `<intType>` types. The `oneapi::mkl::sparse::gemm` routine computes a sparse matrix-dense matrix product defined as

$$C \leftarrow \alpha \cdot \text{op}(A) \cdot \text{op}(B) + \beta \cdot C$$

where α and β are scalars, A is a sparse matrix, B and C are dense matrices, $\text{op}()$ is a matrix modifier for A and B using the following description:

$$\text{op}(A) = \begin{cases} A, & \text{oneapi::mkl::transpose::nontrans} \\ A^T, & \text{oneapi::mkl::transpose::trans} \\ A^H, & \text{oneapi::mkl::transpose::conjtrans} \end{cases}$$

and $\text{op}(A)$ is an m -by- k matrix, $\text{op}(B)$ is a k -by- n matrix, and C is an m -by- n matrix.

Dense matrix storage is in either row-major or column-major format. Sparse matrix formats are compressed sparse row (CSR) formats.

gemm (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {
    void gemm (sycl::queue &queue,
              oneapi::mkl::layout dense_matrix_layout,
              oneapi::mkl::transpose transpose_A,
              oneapi::mkl::transpose transpose_B,
              const fp alpha,
              oneapi::mkl::sparse::matrix_handle_t A_handle,
              sycl::buffer<fp, 1> &B,
              const std::int64_t columns,
              const std::int64_t ldb,
              const fp beta,
              sycl::buffer<fp, 1> &C,
              const std::int64_t ldc);
}
```

Input parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

dense_matrix_layout Specifies the storage scheme in memory for the dense matrices. Note that this layout applies to both B and C dense matrices. The possible options are described in *layout* enum class.

transpose_A Specifies operation `op()` on input matrix A . The possible options are described in *transpose* enum class.

transpose_B Specifies operation `op()` on input matrix B . The possible options are described in *transpose* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix, A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

B

The input dense matrix B in the sparse matrix-dense matrix product. B is a one dimensional SYCL memory object containing an array of size:

	B not transposed	B transposed
Row major	B is an k-by-columns matrix so must have size at least $k*\text{ldb}$.	B is an columns-by-k matrix so must have size at least $\text{columns}*\text{ldb}$
Column major	B is an k-by-columns matrix so must have size at least $\text{ldb}*\text{columns}$.	B is an columns-by-k matrix so must have size at least $\text{ldb}*k$

See *Matrix Storage* for more details.

columns Number of columns of matrix C .

ldb

Specifies the leading dimension of matrix B . It must be positive.

	B not transposed	B transposed
Row major	ldb must be at least columns.	ldb must be at least k.
Column major	ldb must be at least k.	ldb must be at least columns.

beta Specifies the scalar β .

C The dense matrix input/output array. A one-dimensional SYCL memory object containing an array of size at least $m*\text{ldc}$ if `row_major` layout is used to store dense matrices or at least $\text{ldc}*\text{columns}$ if `column_major` layout is used to store dense matrices.

ldc Specifies the leading dimension of matrix C . Must be positive and at least `columns` if `row major` layout is used to store dense matrices or at least `m` if `column major` layout is used to store dense matrices.

Output Parameters

C Dense matrix output is overwritten by the updated matrix, C .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error
oneapi::mkl::device_bad_alloc
oneapi::mkl::host_bad_alloc
oneapi::mkl::invalid_argument
oneapi::mkl::unimplemented
oneapi::mkl::uninitialized
oneapi::mkl::unsupported_device

gemm (USM version)

Syntax

```
namespace oneapi::mkl::sparse {
    sycl::event gemm (sycl::queue &queue,
                    oneapi::mkl::layout dense_matrix_layout,
                    oneapi::mkl::transpose transpose_A,
                    oneapi::mkl::transpose transpose_B,
                    const fp alpha,
                    oneapi::mkl::sparse::matrix_handle_t A_handle,
                    const fp *B,
                    const std::int64_t columns,
                    const std::int64_t ldb,
                    const fp beta,
                    const fp *C,
                    const std::int64_t ldc,
                    const std::vector<sycl::event> &dependencies = {});
}
```

Input parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

dense_matrix_layout Specifies the storage scheme in memory for the dense matrices. Note that this layout applies to both *B* and *C* dense matrices. The possible options are described in *layout* enum class.

transpose_A Specifies operation $\text{op}()$ on input matrix *A*. The possible options are described in *transpose* enum class.

transpose_B Specifies operation $\text{op}()$ on input matrix *B*. The possible options are described in *transpose* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix, *A*. Created using the `oneapi::mkl::sparse::set_csr_data` routine.

B

The dense matrix in the sparse-dense matrix product. A device accessible USM object containing an array of size:

	B not transposed	B transposed
Row major	B is an k-by-columns matrix so must have size at least $k*\text{ldb}$.	B is an columns-by-k matrix so must have size at least $\text{columns}*\text{ldb}$
Column major	B is an k-by-columns matrix so must have size at least $\text{ldb}*\text{columns}$.	B is an columns-by-k matrix so must have size at least $\text{ldb}*k$

See *Matrix Storage* for more details.

columns Number of columns of matrix C .

ldb

Specifies the leading dimension of matrix B . It must be positive.

	B not transposed	B transposed
Row major	ldb must be at least columns.	ldb must be at least k.
Column major	ldb must be at least k.	ldb must be at least columns.

beta Specifies the scalar beta.

C The dense matrix input/output array. A device accessible USM object containing an array of size at least $m*\text{ldc}$ if row_major layout is used to store dense matrices or at least $\text{ldc}*\text{columns}$ if column_major layout is used to store dense matrices.

ldc Specifies the leading dimension of matrix C . Must be positive and at least columns if row major layout is used to store dense matrices or at least m if column major layout is used to store dense matrices.

dependencies List of events that oneapi::mkl::sparse::gemm routine depends on. If omitted, defaults to no dependencies.

Output Parameters

C Dense matrix output is overwritten by the updated matrix C .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

Return Values

Output event that can be waited upon or added as a dependency for the completion of gemm routine.

Parent topic: *Sparse BLAS*

gemv

Computes a sparse matrix-dense vector product.

Description and Assumptions

Refer to *Supported Types* for a list of supported `<fp>` and `<intType>`. The `oneapi::mkl::sparse::gemv` routine computes a sparse matrix-dense vector product defined as

$$y \leftarrow \alpha \text{op}(A)x + \beta y$$

where α and β are scalars, x and y are dense vectors, A is a sparse matrix.

gemv (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {
    void gemv (sycl::queue                &queue,
              oneapi::mkl::transpose     transpose_val,
              const fp                    alpha,
              oneapi::mkl::sparse::matrix_handle_t A_handle,
              sycl::buffer<fp, 1>        &x,
              const fp                    beta,
              sycl::buffer<fp, 1>        &y);
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix, A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x SYCL memory object containing an array of size at least equal to the number of columns of matrix `op(A)`.

beta Specifies the scalar β .

y SYCL memory object containing an array of size at least equal to the number of rows of matrix `op(A)`.

Output Parameters

y Overwritten by the updated vector **y**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

gemv (USM version)

Syntax

```
namespace oneapi::mkl::sparse {
    sycl::event gemv (sycl::queue                &queue,
                    oneapi::mkl::transpose     transpose_val,
                    const fp                    alpha,
                    oneapi::mkl::sparse::matrix_handle_t A_handle,
                    const fp                    *x,
                    const fp                    beta,
                    const fp                    *y,
                    const std::vector<sycl::event> &dependencies = {});
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

transpose_val Specifies operation $\text{op}(C)$ on input matrix. The possible options are described in *transpose* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix, A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x Device-accessible USM object containing an array of size at least equal to the number of columns of matrix $\text{op}(A)$.

beta Specifies the scalar β .

y Device-accessible USM object containing an array of size at least equal to the number of rows of matrix $\text{op}(A)$.

dependencies List of events that `oneapi::mkl::sparse::gemv` routine depends on. If omitted, defaults to no dependencies.

Output Parameters

y Overwritten by the updated vector **y**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

Return Values

Output event that can be waited upon or added as a dependency for the completion of gemv routine.

Parent topic: *Sparse BLAS*

gemvdot

Computes a sparse matrix-dense vector product with dot product.

Description and Assumptions

Refer to *Supported Types* for a list of supported `<fp>` and `<intType>`. The `oneapi::mkl::sparse::gemvdot` routine computes a sparse matrix-dense vector product and dot product defined as

$$y \leftarrow \alpha \text{op}(A)x + \beta y$$

$$d \leftarrow xy$$

where:

A is a general sparse matrix, α , β , and **d** are scalars, **x** and **y** are dense vectors.

gemvdot (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {
    void gemvdot (sycl::queue                &queue,
                 oneapi::mkl::transpose    transpose_val,
```

(continues on next page)

(continued from previous page)

```

        fp                alpha,
        oneapi::mkl::sparse::matrix_handle_t A_handle,
        sycl::buffer<fp, 1> &x,
        fp                beta,
        sycl::buffer<fp, 1> &y,
        sycl::buffer<fp, 1> &d);
}

```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

transpose_val Specifies operation $op()$ on input matrix. The possible options are described in *transpose* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x SYCL memory object containing an array of size at least equal to the number of columns of matrix $op(A)$.

beta Specifies the scalar β .

y SYCL memory object containing an array of size at least equal to the number of rows of matrix $op(A)$.

d SYCL scalar memory object used to store the result of dot product.

Output Parameters

y Overwritten by the updated vector y .

d Overwritten by the dot product of x and y .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

gemvdot (USM version)

Syntax

```

namespace oneapi::mkl::sparse {
    sycl::event gemvdot (sycl::queue &queue,
                        oneapi::mkl::transpose transpose_val,
                        fp alpha,
                        oneapi::mkl::sparse::matrix_handle_t A_handle,
                        fp *x,
                        fp beta,
                        fp *y,
                        fp *d,
                        const std::vector<sycl::event> &dependencies = {});
}

```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

transpose_val Specifies operation $op()$ on input matrix. The possible options are described in *transpose* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x Device-accessible USM object containing an array of size at least equal to the number of columns of matrix $op(A)$.

beta Specifies the scalar β .

y Device-accessible USM object containing an array of size at least equal to the number of rows of matrix $op(A)$

d Device-accessible USM scalar object used to store the result of dot product.

dependencies List of events that `oneapi::mkl::sparse::gemvdot` routine depends on. If omitted, defaults to no dependencies.

Output Parameters

y Overwritten by the updated vector y .

d Overwritten by the dot product of x and y .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented
oneapi::mkl::uninitialized
oneapi::mkl::unsupported_device

Return Values

Output event that can be waited upon or added as a dependency for the completion of gemvdot routine.

Parent topic: *Sparse BLAS*

optimize_gemv

Performs internal optimizations for `oneapi::mkl::sparse::gemv` by analyzing the matrix structure.

Description and Assumptions

The `oneapi::mkl::sparse::optimize_gemv` routine analyzes matrix structure and performs optimizations. Optimized data is then stored in the handle.

optimize_gemv (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {
    void optimize_gemv (sycl::queue                &queue,
                      oneapi::mkl::transpose     transpose_val,
                      oneapi::mkl::sparse::matrix_handle_t handle);
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

handle Handle to object containing sparse matrix and other internal data. Created using the `oneapi::mkl::sparse::set_csr_data` routine.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error
oneapi::mkl::device_bad_alloc
oneapi::mkl::host_bad_alloc
oneapi::mkl::invalid_argument
oneapi::mkl::unimplemented
oneapi::mkl::uninitialized
oneapi::mkl::unsupported_device

optimize_gemv (USM version)

Syntax

```
namespace oneapi::mkl::sparse {
    sycl::event optimize_gemv (sycl::queue                &queue,
                             oneapi::mkl::transpose    transpose_val,
                             oneapi::mkl::sparse::matrix_handle_t handle,
                             std::vector<sycl::event>    &dependencies);
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

handle Handle to object containing sparse matrix and other internal data. Created using the `oneapi::mkl::sparse::set_csr_data` routine.

dependencies List of events that `oneapi::mkl::sparse::optimize_gemv` routine depends on.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error
oneapi::mkl::device_bad_alloc
oneapi::mkl::host_bad_alloc
oneapi::mkl::invalid_argument
oneapi::mkl::unimplemented
oneapi::mkl::uninitialized

`oneapi::mkl::unsupported_device`

Return Values

Output event that can be waited upon or added as a dependency for the completion of `optimize_gemv` routine.

Parent topic: *Sparse BLAS*

symv

Computes a sparse matrix-dense vector product for a symmetric part of the sparse matrix.

Description and Assumptions

Refer to *Supported Types* for a list of supported `<fp>` and `<intType>`. The `oneapi::mkl::sparse::symv` routine computes a sparse matrix-dense vector product over a symmetric part defined as

$$y \leftarrow \alpha Ax + \beta y$$

where:

α and β are scalars, x and y are dense vectors, A is a sparse matrix.

symv (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {
    void symv (sycl::queue          &queue,
              oneapi::mkl::uplo    uplo_val,
              fp                    alpha,
              oneapi::mkl::sparse::matrix_handle_t A_handle,
              sycl::buffer<fp, 1>   &x,
              fp                    beta,
              sycl::buffer<fp, 1>   &y);
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in `uplo` enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x SYCL memory object containing an array of size at least equal to the number of columns of A matrix.

beta Specifies the scalar β .

y SYCL memory object containing an array of size at least equal to the number of rows of A matrix.

Output Parameters

y Overwritten by the updated vector **y**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

symv (USM version)

Syntax

```
namespace oneapi::mkl::sparse {
    sycl::event symv (sycl::queue &queue,
                    oneapi::mkl::uplo uplo_val,
                    fp alpha,
                    oneapi::mkl::sparse::matrix_handle_t A_handle,
                    fp *x,
                    fp beta,
                    fp *y,
                    const std::vector<sycl::event> &dependencies = {});
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix *A*. Created using the *oneapi::mkl::sparse::set_csr_data* routine.

x Device-accessible USM object containing an array of size at least equal to the number of columns of *A* matrix.

beta Specifies the scalar β .

y Device-accessible USM object containing an array of size at least equal to the number of rows of *A* matrix.

dependencies List of events that *oneapi::mkl::sparse::symv* routine depends on. If omitted, defaults to no dependencies.

Output Parameters

y Overwritten by the updated vector **y**.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error
oneapi::mkl::device_bad_alloc
oneapi::mkl::host_bad_alloc
oneapi::mkl::invalid_argument
oneapi::mkl::unimplemented
oneapi::mkl::uninitialized
oneapi::mkl::unsupported_device

Return Values

Output event that can be waited upon or added as a dependency for the completion of `symv` routine.

Parent topic: *Sparse BLAS*

trmv

Computes a sparse matrix-dense vector product over upper or lower triangular matrix parts.

Description and Assumptions

Refer to *Supported Types* for a list of supported `<fp>` and `<intType>`. The `oneapi::mkl::sparse::trmv` routine computes a sparse matrix-dense vector product over a triangular part defined as

$$y \leftarrow \alpha \text{op}(A)x + \beta y$$

where: *alpha* and *beta* are scalars, *x* and *y* are dense vectors, *A* is a sparse matrix.

trmv (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {

    void trmv (sycl::queue                &queue,
              oneapi::mkl::uplo          uplo_val,
              oneapi::mkl::transpose     transpose_val,
              oneapi::mkl::diag          diag_val,
              fp                          alpha,
```

(continues on next page)

(continued from previous page)

```

oneapi::mkl::sparse::matrix_handle_t A_handle,
sycl::buffer<fp, 1>                    &x,
fp                                      beta,
sycl::buffer<fp, 1>                    &y);
}

```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

diag_val Specifies if the diagonal is unit or not. The possible options are described in *diag* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x SYCL memory object containing an array of size at least equal to the number of columns of matrix $op(A)$.

beta Specifies the scalar β .

y SYCL memory object containing an array of size at least equal to the number of rows of matrix $op(A)$.

Output Parameters

y Overwritten by the updated vector y .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

trmv (USM version)

Syntax

```

namespace oneapi::mkl::sparse {

    sycl::event trmv (sycl::queue &queue,
                    oneapi::mkl::uplo uplo_val,
                    oneapi::mkl::transpose transpose_val,
                    oneapi::mkl::diag diag_val,
                    fp alpha,
                    oneapi::mkl::sparse::matrix_handle_t A_handle,
                    fp *x,
                    fp beta,
                    fp *y,
                    const std::vector<sycl::event> &dependencies = {});

}

```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

transpose_val Specifies operation $op()$ on input matrix. The possible options are described in *transpose* enum class.

diag_val Specifies if the diagonal is unit or not. The possible options are described in *diag* enum class.

alpha Specifies the scalar α .

A_handle Handle to object containing sparse matrix A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x Device-accessible USM object containing an array of size at least equal to the number of columns of matrix $op(A)$.

beta Specifies the scalar β .

y Device-accessible USM object containing an array of size at least equal to the number of rows of matrix $op(A)$.

dependencies List of events that `oneapi::mkl::sparse::trmv` routine depends on. If omitted, defaults to no dependencies.

Output Parameters

y Overwritten by the updated vector y .

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error
oneapi::mkl::device_bad_alloc
oneapi::mkl::host_bad_alloc
oneapi::mkl::invalid_argument
oneapi::mkl::unimplemented
oneapi::mkl::uninitialized
oneapi::mkl::unsupported_device

Return Values

Output event that can be waited upon or added as a dependency for the completion of trmv routine.

Parent topic: *Sparse BLAS*

optimize_trmv

Performs internal optimizations for `oneapi::mkl::sparse::trmv` by analyzing the matrix structure.

Description and Assumptions

The `oneapi::mkl::sparse::optimize_trmv` routine analyzes matrix structure and performs optimizations. Optimized data is then stored in the handle.

optimize_trmv (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {
    void optimize_trmv (sycl::queue          &queue,
                      oneapi::mkl::uplo    uplo_val,
                      oneapi::mkl::transpose transpose_val,
                      oneapi::mkl::diag    diag_val,
                      oneapi::mkl::sparse::matrix_handle_t handle);
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

diag_val Specifies if the diagonal is unit or not. The possible options are described in *diag* enum class.

handle Handle to object containing sparse matrix and other internal data. Created using the `oneapi::mkl::sparse::set_csr_data` routine.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

optimize_trmv (USM version)

Syntax

```
namespace oneapi::mkl::sparse {
    sycl::event optimize_trmv (sycl::queue                &queue,
                             oneapi::mkl::uplo          uplo_val,
                             oneapi::mkl::transpose     transpose_val,
                             oneapi::mkl::diag          diag_val,
                             oneapi::mkl::sparse::matrix_handle_t handle,
                             std::vector<sycl::event>    &dependencies);
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

diag_val Specifies if the diagonal is unit or not. The possible options are described in *diag* enum class.

handle Handle to object containing sparse matrix and other internal data. Created using the `oneapi::mkl::sparse::set_csr_data` routine.

dependencies List of events that `oneapi::mkl::sparse::optimize_trmv` routine depends on.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

Return Values

Output event that can be waited upon or added as a dependency for the completion of `optimize_trmv` routine.

Parent topic: *Sparse BLAS*

trsv

Solves a system of linear equations for a triangular sparse matrix.

Description and Assumptions

Refer to *Supported Types* for a list of supported `<fp>` and `<intType>`. The `oneapi::mkl::sparse::trsv` routine solves a system of linear equations for a square matrix:

$$\text{op}(A)y \leftarrow x$$

where: A is a triangular sparse matrix of size m rows by m columns, op is a matrix modifier for matrix A, x and y are dense vectors of length at least m.

trsv (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {
    void trsv (sycl::queue          &queue,
              oneapi::mkl::uplo    uplo_val,
              oneapi::mkl::transpose transpose_val,
              oneapi::mkl::diag    diag_val,
              oneapi::mkl::sparse::matrix_handle_t A_handle,
              sycl::buffer<fp, 1>  &x,
```

(continues on next page)

(continued from previous page)

```

sycl::buffer<fp, 1>          &y);
}

```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

transpose_val Specifies operation $op()$ on input matrix. The possible options are described in *transpose* enum class.

diag_val Specifies if the diagonal is unit or not. The possible options are described in *diag* enum class.

A_handle Handle to object containing sparse matrix A . Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x SYCL memory object containing an array of size at least equal to the number of columns of matrix $op(A)$.

y SYCL memory object containing an array of size at least equal to the number of rows of matrix $op(A)$.

Output Parameters

y SYCL memory object containing an array of size at least `nRows` filled with the solution to the system of linear equations.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

trsv (USM version)

Syntax

```

namespace oneapi::mkl::sparse {
    sycl::event trsv (sycl::queue          &queue,
                    oneapi::mkl::uplo    uplo_val,
                    oneapi::mkl::transpose transpose_val,
                    oneapi::mkl::diag     diag_val,
                    oneapi::mkl::sparse::matrix_handle_t A_handle,

```

(continues on next page)

(continued from previous page)

```

        fp                                     *x,
        fp                                     *y
        const std::vector<sycl::event>        &dependencies = {});
}

```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

diag_val Specifies if the diagonal is unit or not. The possible options are described in *diag* enum class.

A_handle Handle to object containing sparse matrix *A*. Created using the `oneapi::mkl::sparse::set_csr_data` routine.

x Device-accessible USM object containing an array of size at least equal to the number of columns of matrix `op(A)`.

y Device-accessible USM object containing an array of size at least equal to the number of rows of matrix `op(A)`.

dependencies List of events that `oneapi::mkl::sparse::trmv` routine depends on. If omitted, defaults to no dependencies.

Output Parameters

y Device-accessible USM object containing an array of size at least `nRows` filled with the solution to the system of linear equations.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented

oneapi::mkl::uninitialized

oneapi::mkl::unsupported_device

Return Values

Output event that can be waited upon or added as a dependency for the completion of trmv routine.

Parent topic: *Sparse BLAS*

optimize_trsv

Performs internal optimizations for `oneapi::mkl::sparse::trsv` by analyzing the matrix structure.

Description and Assumptions

The `oneapi::mkl::sparse::optimize_trsv` routine analyzes matrix structure and performs optimizations. Optimized data is then stored in the handle.

optimize_trsv (Buffer version)

Syntax

```
namespace oneapi::mkl::sparse {
    void optimize_trsv (sycl::queue          &queue,
                      oneapi::mkl::uplo    uplo_val,
                      oneapi::mkl::transpose transpose_val,
                      oneapi::mkl::diag     diag_val,
                      oneapi::mkl::sparse::matrix_handle_t handle);
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

diag_val Specifies if the diagonal is unit or not. The possible options are described in *diag* enum class.

handle Handle to object containing sparse matrix and other internal data. Created using the `oneapi::mkl::sparse::set_csr_data` routine.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error

oneapi::mkl::device_bad_alloc

oneapi::mkl::host_bad_alloc

oneapi::mkl::invalid_argument

oneapi::mkl::unimplemented
oneapi::mkl::uninitialized
oneapi::mkl::unsupported_device

optimize_trmv (USM version)

Syntax

```
namespace oneapi::mkl::sparse {
    sycl::event optimize_trsv (sycl::queue &queue,
                             oneapi::mkl::uplo uplo_val,
                             oneapi::mkl::transpose transpose_val,
                             oneapi::mkl::diag diag_val,
                             oneapi::mkl::sparse::matrix_handle_t handle,
                             std::vector<sycl::event> &dependencies);
}
```

Input Parameters

queue Specifies the SYCL command queue which will be used for SYCL kernels execution.

uplo_val Specifies which part is to be processed. The possible options are described in *uplo* enum class.

transpose_val Specifies operation `op()` on input matrix. The possible options are described in *transpose* enum class.

diag_val Specifies if the diagonal is unit or not. The possible options are described in *diag* enum class.

handle Handle to object containing sparse matrix and other internal data. Created using the `oneapi::mkl::sparse::set_csr_data` routine.

dependencies List of events that `oneapi::mkl::sparse::optimize_trsv` routine depends on.

Throws

This routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here.

oneapi::mkl::computation_error
oneapi::mkl::device_bad_alloc
oneapi::mkl::host_bad_alloc
oneapi::mkl::invalid_argument
oneapi::mkl::unimplemented
oneapi::mkl::uninitialized
oneapi::mkl::unsupported_device

Return Values

Output event that can be waited upon or added as a dependency for the completion of `optimize_trsv` routine.

Parent topic: *Sparse BLAS*

Supported Types

Data Types <fp>	Integer Types <intType>
float	std::int32_t
double	std::int64_t
std::complex<float>	
std::complex<double>	

General descriptions

matrix_handle_t

Type for the `handle` that can be used to store information about the initial sparse matrix (represented in a sparse format) and data created/obtained during the analysis stage to be used in the execution stage.

Sparse storage formats

CSR

There are a variety of matrix storage formats available for representing the sparse matrix. One of the most popular is compressed sparse row (CSR) format, that is represented by three arrays: `row_ptr`, `col_ind` and `val`, and `index` parameter.

num_rows	Number of rows in the sparse matrix.
num_cols	Number of columns in the sparse matrix.
in-index	Parameter that is used to specify whether the matrix has zero or one-based indexing.
val	An array that contains the non-zero elements of the sparse matrix stored row by row.
col_ind	An integer array of column indices for non-zero elements stored in the <code>val</code> array, such that <code>col_ind[i]</code> is the column number (using zero- or one-based indexing) of the element of the sparse matrix stored in <code>val[i]</code> .
row_ptr	An integer array of size equal to <code>num_rows + 1</code> . Element <code>j</code> of this integer array gives the position of the element in the <code>val</code> array that is first non-zero element in a row <code>j</code> of <code>A</code> . Note that this position is equal to <code>row_ptr[j] - index</code> . Last element of the <code>row_ptr</code> array (<code>row_ptr[num_rows]</code>) stores the sum of, number of nonzero elements and <code>index*(number of nonzero elements + *index)</code> .

A sparse matrix can be represented in a CSR format in a following way (assuming zero-based indexing):

$$A = \begin{pmatrix} 1 & 0 & 2 \\ 0 & -1 & 4 \\ 3 & 0 & 0 \end{pmatrix}$$

num_rows	3				
num_cols	3				
index	0				
val	1	2	-1	4	3
col_ind	0	2	1	2	0
row_ptr	0	2	4	5

11.2.3 Discrete Fourier Transforms

The *Discrete Fourier Transform Functions* offer several options for computing Discrete Fourier Transforms (DFTs).

Discrete Fourier Transform Functions

The general form of the d-dimensional discrete Fourier transform(DFT) is

$$z_{k_1, k_2, \dots, k_d} = \sigma \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left[\delta 2\pi i \left(\sum_{\ell=1}^d \frac{j_\ell k_\ell}{n_\ell} \right) \right].$$

for $k_\ell = 0, \dots, n_\ell - 1$ and $\ell \in \{1, \dots, d\}$, where σ is a scale factor, $\delta = -1$ for the forward transform, and $\delta = +1$ for the backward(inverse) transform. In the forward transform, the input sequence $(w_{j_1, j_2, \dots, j_d})$ belongs to the set of complex-valued sequences or real-valued sequences. Respective domains for the backward transform are represented by complex-valued sequences or complex conjugate-even sequences.

The discrete Fourier transform to be performed is defined by the creation of a *descriptor* class, with the associated configuration parameters, described in *Configuration Parameters and Enums*. Once the descriptor class is defined and *commit* is called and provided with a `sycl::queue` to define the device and context, it can be used for computing the forward and/or backward transformations. The available data storage formats for the various configurations are described in *Storage Formats*.

The routines and objects associated with computing a discrete Fourier transform.

Routines and Objects	Description
<i>descriptor</i>	A class to define the specific discrete Fourier transform problem to be applied.
<i>descriptor::set_value</i>	A member function of descriptor class to set non-default configuration parameters and define the DFT transformation to be applied.
<i>descriptor::get_value</i>	A member function of descriptor class to query configuration parameters that define the DFT transformation to be applied.
<i>descriptor::commit</i>	A member function of descriptor class to finalize the DFT descriptor before computations.
<i>compute_forward</i>	Computes the in-place/out-of-place forward transformation.
<i>compute_backward</i>	Computes the in-place/out-of-place backward transformation.

Parent topic: *oneMKL Domains*

Configuration Parameters and Enums

The following enum classes are defined in the `oneapi::mkl::dft` namespace which are used for configuring the discrete Fourier transform problem in the `descriptor` class prior to a call to `commit`.

enum class	Description
<code>precision</code>	The floating-point precision in which the transform is carried out. Used as a template argument for <code>descriptor</code> class.
<code>domain</code>	The forward domain data type for dft transformation. Used as a template argument for <code>descriptor</code> class.
<code>con-fig_param</code>	The configuration parameters to specify the DFT transformation desired. These can be set and retrieved via the <code>set_value</code> and <code>get_value</code> functions.
<code>con-fig_value</code>	Some possible enum values that the <code>config_param</code> configuration parameters can take on.

precision

The floating-point precision in which the transform is to be carried out. The data must be presented in this precision, the computation is carried out in this precision, and the result is delivered in this precision.

Syntax

```
enum class precision {
    SINGLE,
    DOUBLE
};
```

Value	Description
SINGLE	data and transforms are executed using single(fp32) precision
DOUBLE	data and transforms are executed using double(fp64) precision

domain

The discrete Fourier transform supports forward transformations on input sequences of two domains, from the forward domain to the backward domain. The backward transformation operates on input sequences from the backward domain to the forward domain. This `domain` value defines the forward domain and the backward domain is always implied to be complex-valued.

Syntax

```
enum class domain {
    REAL,
    COMPLEX
};
```

Value	Forward domain	Backward domain	Description
REAL	real-valued	complex-valued	Forward transformation is real-to-complex, backward transform is complex-to-real.
COMPLEX	complex-valued	complex-valued	Forward and backward transformations are complex-to-complex.

config_param

```
enum class config_param {
    FORWARD_DOMAIN,
    DIMENSION,
    LENGTHS,
    PRECISION,

    FORWARD_SCALE,
    BACKWARD_SCALE,

    NUMBER_OF_TRANSFORMS,

    COMPLEX_STORAGE,
    REAL_STORAGE,
    CONJUGATE_EVEN_STORAGE,

    PLACEMENT,

    INPUT_STRIDES,
    OUTPUT_STRIDES,

    FWD_DISTANCE,
    BWD_DISTANCE,

    WORKSPACE,
    ORDERING,
    TRANSPOSE,
    PACKED_FORMAT,
    COMMIT_STATUS
};
```

Many of the `config_param` enum's will take values in `config_value` or other `std::int64_t`, `std::vector<std::int64_t>`, or floating-point *precision* values as specified in the following table.

Value	Description
FORWARD_DOMAIN	Read-only value of forward <i>domain</i> set at <i>descriptor</i> construction time.
DIMENSION	Read-only value of the dimension of the transformation. Value is a positive integer of type <code>std::int64_t</code> set at <i>descriptor</i> construction.
LENGTHS	For a one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar (<code>std::int64_t</code>). For multi-dimensional (≥ 2) transform, the lengths of each of the dimensions are supplied in an integer vector (<code>std::vector<std::int64_t></code>) at <i>descriptor</i> construction time.
PRECISION	Read-only value of <i>precision</i> set at <i>descriptor</i> construction time.
FORWARD_SCALE	The forward transform is associated with a scale factor, σ , of real floating-point type <i>precision</i> , the default value is 1.0.
BACKWARD_SCALE	The backward transform is associated with a scale factor, σ , of real floating-point type <i>precision</i> , the default value is 1.0.
NUMBER_OF_TRANSFORMS	If you need to perform a large number of identical DFTs, you can do this in a single call to a compute function with the value of this equal to the actual number of the transforms. Takes a value of <code>std::int64_t</code> with default value of 1.
COMPLEX_STORAGE	Specifies the data storage format for <i>domain</i> with value of COMPLEX.
REAL_STORAGE	Specifies the data storage format for <i>domain</i> with value of REAL.
CONJUGATE_EVEN_STORAGE	Specifies the data storage format using conjugate-even symmetry of the data which allows to store only half of the mathematical results.
PLACEMENT	Choose between in-place (value is <code>config_value::INPLACE</code>) and out-of-place (value is <code>config_value::NOT_INPLACE</code>) transformations. For in-place transformation, the computational functions overwrite the input data with the output results. The default is <code>config_value::INPLACE</code> . When the configuration parameter is set to <code>config_value::NOT_INPLACE</code> , the input and output data sets must have no common elements.
INPUT_STRIDES	Defines the layout of multi-dimensional input data in computer memory. The value for a d-dimensional data set is a d-dimensional vector of type <code>std::vector<std::int64_t></code> representing offsets of elements of the appropriate data type as specified in <i>INPUT_STRIDES</i> and <i>OUTPUT_STRIDES</i> .
OUTPUT_STRIDES	Defines the layout of multi-dimensional output data in computer memory. The value for a d-dimensional data set is a d-dimensional vector of type <code>std::vector<std::int64_t></code> representing offsets of elements of the appropriate data type as specified in <i>INPUT_STRIDES</i> and <i>OUTPUT_STRIDES</i> .
FWD_DISTANCE	If computing multiple (batched) transforms, this parameter specifies the distance (in elements) between the first data elements of consecutive data sets in the forward domain. Provided in type <code>std::int64_t</code> , the default value is 1.
BWD_DISTANCE	If computing multiple (batched) transforms, this parameter specifies the distance (in elements) between the first data elements of consecutive data sets in the backward domain. Provided in type <code>std::int64_t</code> , the default value is 1.
WORKSPACE	Some FFT algorithm computation steps require a scratch space for permutations or other purposes. To manage the use of auxiliary storage, set to <code>config_value::ALLOW</code> to permit the use of auxiliary storage and <code>config_value::AVOID</code> to avoid using auxiliary storage if possible.
ORDERING	Some FFT algorithms apply an explicit permutation stage that can be time consuming. The value of <code>config_value::ORDERED</code> (default) applies the data ordering for all transformations. The value of <code>config_value::BACKWARD_SCRAMBLED</code> applies ordering for forward transform, but allows backward transform to have scrambled data if it gives a performance advantage.
TRANSPOSE	A boolean value to indicate providing the transposition of output results (for multi-dimensional transforms). Default value is <code>false</code> .
PACKED_FORMAT	Packing format for complex domain data storage of finite conjugate-even sequences from real-to-complex or complex-to-real transformations.
COMMIT_STATUS	Read-only value indicates whether the descriptor is ready for computation after a successful <i>commit</i> . Value of <code>config_value::COMMITTED</code> indicates a successful call to <i>commit</i> . A value of <code>config_value::UNCOMMITTED</code> (default) is set after descriptor constructor call and before successful call to <i>commit</i> .

config_value

These are some of the non-integer/floating-point values that the *config_param* configuration parameters can take on.

```

enum class config_value {

    // for config_param::COMMIT_STATUS
    COMMITTED,
    UNCOMMITTED,

    // for config_param::COMPLEX_STORAGE,
    //   config_param::REAL_STORAGE and
    //   config_param::CONJUGATE_EVEN_STORAGE
    COMPLEX_COMPLEX,
    REAL_COMPLEX,
    REAL_REAL,

    // for config_param::PLACEMENT
    INPLACE,
    NOT_INPLACE,

    // for config_param::ORDERING
    ORDERED,
    BACKWARD_SCRAMBLED,

    // Allow/avoid certain usages
    ALLOW,
    AVOID,
    NONE,

    // for config_param::PACKED_FORMAT for storing conjugate-even finite sequence in real_
    ↪ containers
    CCE_FORMAT

};

```

Parent topic: *Discrete Fourier Transform Functions*

Forward and Backward Scale

The forward and backward transformations are each associated with a scale factor, σ , having the default value of 1. For example, for a one-dimensional transform of length n , you can use the default scale of 1 for the forward transform and set the scale factor for the backward transform to be $1/n$, thus making the backward transform the inverse of the forward transform. Use real floating point data type corresponding to *precision*.

Parent topic *Configuration Parameters and Enums*

Number of Transforms

If you need to perform a large number of identical DFTs, you can do this in a single call to a `compute*` function with the value of this configuration parameter equal to the actual number of the transforms. The default value is 1. You can set this parameter to a positive integer value using the `std::int64_t` data type.

When setting the number of transforms to a value greater than one, you also need to specify the distance between the forward data sets and the distance between the backward data sets using the `config_param::FWD_DISTANCE` and `config_param::BWD_DISTANCE` configuration parameters corresponding to the specified *domain*.

Note:

- The data sets must not have common elements
 - All the sets of data in each domain must be located within the same memory block.
-

Parent topic *Configuration Parameters and Enums*

Storage Formats

Depending on the value of the *domain* template value, the implementation of the DFT supports several storage schemes for input and output data. (See Charles Van Loan, *Computational Frameworks for the Fast Fourier Transform*, SIAM, Philadelphia, 1992 for motivation of these schemes).

The data elements are placed within contiguous memory blocks, defined with generalized strides (see *INPUT_STRIDES and OUTPUT_STRIDES*). For multiple transforms, all sets of data should be located within the same memory block, and the data sets should be placed at the same distance from each other (see *NUMBER_OF TRANSFORMS* and `config_param::FWD_DISTANCE`, `config_param::BWD_DISTANCE`).

The input data and strides sizes are stored and offsets counted in terms of elements of the data type (complex or real) based on the storage format and *forward domain* as seen in *Element types for complex-to-complex transformation and COMPLEX_STORAGE*, *Element types for real-to-complex transformations and REAL_STORAGE* and *Element types for real-to-complex transformations and CONJUGATE_EVEN_STORAGE*.

COMPLEX_STORAGE

For the *domain* template parameter with value `COMPLEX`, both input and output sequences belong to the complex domain. In this case, the configuration parameter `COMPLEX_STORAGE` can have one of the two values: `COMPLEX_COMPLEX` (default) or `REAL_REAL`.

COMPLEX_COMPLEX

With the `config_value::COMPLEX_COMPLEX` storage, complex-valued data sequences are stored in a single complex container (`array/sycl::buffer`), `AZ`, so that a complex-valued element z_{k_1, k_2, \dots, k_d} of the m -th d -dimensional sequence is accessed at `AZ[m * distance + stride0 + k1 * stride1 + k2 * stride2 + ... + kd * strided]` as a structure consisting of the real and imaginary parts. This code illustrates the use of `config_value::COMPLEX_COMPLEX` storage with three dimensions (n_1, n_2, n_3) and m batches:

```
std::complex<datatype> * AZ; // 2*sizeof(datatype)*n1*n2*n3*m
std::vector<std::int64_t> ios; // length 4 of sizes
std::int64_t iodist;
```

```
// ...
// on input: Z(k1,k2,k3,m)
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
compute_forward(descr, AZ); // complex-to-complex in-place FFT
// on output: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

REAL_REAL

With the `config_value::REAL_REAL` storage, complex-valued data sequences are stored by two real containers (arrays/sycl::buffer's), AR and AI, so that a complex-valued element z_{k_1, k_2, \dots, k_d} of the m-th d-dimensional sequence has real part $AR[m * \text{distance} + \text{stride}_0 + k_1 * \text{stride}_1 + k_2 * \text{stride}_2 + \dots + k_d * \text{stride}_d]$ and imaginary part $AI[m * \text{distance} + \text{stride}_0 + k_1 * \text{stride}_1 + k_2 * \text{stride}_2 + \dots + k_d * \text{stride}_d]$. This code illustrates the use of `config_value::REAL_REAL` storage with three dimensions (n_1, n_2, n_3) and m batches:

```
datatype * AR; // sizeof(datatype)*n1*n2*n3*m
datatype * AI; // sizeof(datatype)*n1*n2*n3*m
std::vector<std::int64_t> ios; // length 4 of strides
std::int64_t iodist;

// ...

// on input: Z(k1,k2,k3,m)
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + i*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
compute_forward(descr, AR, AI); // complex-to-complex in-place FFT
// on output: Z{k1,k2,k3,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + i*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

REAL_STORAGE

For the *domain* template parameter with value REAL, only the value of REAL_REAL is supported.

REAL_REAL

With the REAL_REAL storage, real-valued data sequences in a real domain are stored by one real container (array/sycl::buffer), AR, so that a real-valued element r_{k_1, k_2, \dots, k_d} of the m-th d-dimensional sequence is accessed as $AR[m * \text{distance} + \text{stride}_0 + k_1 * \text{stride}_1 + k_2 * \text{stride}_2 + \dots + k_d * \text{stride}_d]$. This code illustrates the use of `config_value::REAL_REAL` storage with three dimensions (n_1, n_2, n_3) and m batches:

```
datatype * AR; // sizeof(datatype)*n1*n2*n3*m
datatype * AI; // sizeof(datatype)*n1*n2*n3*m
std::vector<std::int64_t> ios; // length 4 of strides
std::int64_t iodist;

// ...
```

(continues on next page)

(continued from previous page)

```

// on input: R(k1,k2,k3,m)
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
compute_forward(descr, AR, AI); // real-to-complex in-place FFT
// on output: Z{k1,k2,k3,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + i*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]

```

CONJUGATE_EVEN_STORAGE

For the *domain* template parameter with value REAL and considered as a conjugate-even domain, the value of `config_value::COMPLEX_COMPLEX` is supported. The conjugate-even symmetry of the data enables storing only about a half of the whole mathematical result, so that one part of it can be directly referenced in the memory while the other part can be reconstructed depending on the selected storage configuration. The `config_param::PACKED_FORMAT` configuration parameter defines how the data is packed. Possible values for `config_param::PACKED_FORMAT` depend on the values of the `config_param::CONJUGATE_EVEN_STORAGE` configuration parameter.

CONJUGATE_EVEN_STORAGE	Supported PACKED_FORMATS
<i>COMPLEX_COMPLEX</i>	<code>config_value::CCE_FORMAT</code> can be used with transforms of any dimension.

COMPLEX_COMPLEX

There is only one `config_param::PACKED_FORMAT` supported by the `config_value::COMPLEX_COMPLEX` value for `config_param::CONJUGATE_EVEN_STORAGE`, mainly the `config_value::CCE_FORMAT`. The complex-valued data sequence consists of one complex container (array/sycl::buffer), AZ, so that a complex-valued element z_{k_1, k_2, \dots, k_d} of the m-th d-dimensional sequence can be accessed or reconstructed as follows:

Consider a d-dimensional real-to-complex transform.

Because the input sequence, R, is real-valued, the mathematical result, Z, has conjugate-even symmetry: $z_{k_1, k_2, \dots, k_d} = \text{conjugate}(z_{n_1 - k_1, n_2 - k_2, \dots, n_d - k_d})$, where index arithmetic is performed modulo the length of the respective dimension. Obviously, the first element of the result is real-valued: $z_{0,0,\dots,0} = \text{conjugate}(z_{0,0,\dots,0})$.

For dimensions with even lengths, some of the other elements are real-valued as well. For example, if n_s is even, then $z_{0,0,\dots, \frac{n_s}{2}, 0, \dots, 0} = \text{conjugate}(z_{0,0,\dots, \frac{n_s}{2}, 0, \dots, 0})$. With the conjugate-even symmetry, approximately a half of the result suffices to fully reconstruct it. For an arbitrary dimension, h , it suffices to store elements $z_{k_1, \dots, k_h, \dots, k_d}$ for the following indices:

- $k_h = 0, \dots, \lfloor \frac{n_h}{2} \rfloor$
- $k_i = 0, \dots, n_i - 1$, where $i = 1, \dots, d$ and $i \neq h$

and assuming that integer division rounds down.

The symmetry property enables reconstructing the remaining elements: for $k_h = \lfloor \frac{n_h}{2} \rfloor + 1, \dots, n_h - 1$. The halved dimension is always assumed to be the dimension for which storage is contiguous in memory (see strides), for example in a 2D row-major format, it is the last dimension and for 2D column-major format it is the first dimension.

Packed complex domain formats for a 1D real-to-complex transformation considered as a conjugate-even-domain with COMPLEX_COMPLEX storage and $n = 2L$ (even size) or $n = 2L + 1$ (odd size).

$k =$	0	1	2	...	L-2	L-1	L
CCE	Z_0	Z_1	Z_2	...	Z_{L-2}	Z_{L-1}	Z_L

Packed complex domain formats for a 2D $n_1 \times n_2$ real-to-complex transformations considered as a conjugate-even-domain with COMPLEX_COMPLEX storage and $n_1 = 2K$ (even size) and $n_2 = 2L$ (even size) using row-major input data.

$k_1 \backslash k_2$	0	1	2	...	L-1	L
0	$Z_{0,0}$	$Z_{0,1}$	$Z_{0,2}$...	$Z_{0,L-1}$	$Z_{0,L}$
1	$Z_{1,0}$	$Z_{1,1}$	$Z_{1,2}$...	$Z_{1,L-1}$	$Z_{1,L}$
2	$Z_{2,0}$	$Z_{2,1}$	$Z_{2,2}$...	$Z_{2,L-1}$	$Z_{2,L}$
...
$n_1 - 2$	$Z_{n_1-2,0}$	$Z_{n_1-2,1}$	$Z_{n_1-2,2}$...	$Z_{n_1-2,L-1}$	$Z_{n_1-2,L}$
$n_1 - 1$	$Z_{n_1-1,0}$	$Z_{n_1-1,1}$	$Z_{n_1-1,2}$...	$Z_{n_1-1,L-1}$	$Z_{n_1-1,L}$

The following code illustrates usage of the `config_value::COMPLEX_COMPLEX` storage for a two-dimensional conjugate-even domain with row-major input data:

```
datatype * AR; // sizeof(datatype)*n1*n2*m
std::complex<datatype> * AZ; // sizeof(datatype)*n1*n2*m
std::vector<std::int64_t> is; // length 3 of input strides
std::vector<std::int64_t> os; // length 3 of output strides
std::int64_t idist, odist;

// ...

// on input: R(k1,k2,m)
// = AR[ is[0] + k1*is[1] + k2*is[2] + m*idist ]
compute_forward(descr, AR, AZ); // real-to-complex out-of-place FFT
// on output:
// for k2=0,n2/2: Z{k1,k2,m} = AZ[os[0] + k1*os[1] + k2*os[2] + m*odist]
// for k2=n2/2+1,n2-1: Z{k1,k2,m} = conj(AZ[os[0] + (n1-k1)%n1*os[1]
// + (n2-k2)%n2*os[2] + m*odist])
```

For the backward transform, the input and output parameters and layouts exchange roles. Set the strides describing the layout in the backward/forward domain as input/output strides, respectively. For example:

```
// ...
descr.set_value(config_param::INPUT_STRIDES, fwd_domain_strides);
descr.set_value(config_param::OUTPUT_STRIDES, bwd_domain_strides);
descr.commit(queue);
compute_forward(descr, ...);
// ...
descr.set_value(config_param::INPUT_STRIDES, bwd_domain_strides);
descr.set_value(config_param::OUTPUT_STRIDES, fwd_domain_strides);
descr.commit(queue);
compute_backward(descr, ...);
```

Parent topic *Configuration Parameters and Enums*

INPUT_STRIDES and OUTPUT_STRIDES

The FFT interface provides configuration parameters that define the layout of multidimensional data in the computer memory. For d -dimensional data set, X , defined by dimensions $n_1 \times n_2 \times \dots \times n_d$, the layout describes where a particular element $X(k_1, k_2, \dots, k_d)$ of the data set is located. The memory address of the element $X(k_1, k_2, \dots, k_d)$ is expressed by the formula: $X(k_1, k_2, \dots, k_d) = \text{the } +s_0 + k_1 * s_1 + k_2 * s_2 + \dots + k_d * s_d\text{-th element}$ of the container (`sync1::buffer` or USM pointer) provided to the compute function, where s_0 is the displacement and s_1, \dots, s_d are generalized strides. The configuration parameters `config_param::INPUT_STRIDES` and `config_param::OUTPUT_STRIDES` enable you to get and set these values. The configuration value is a $d+1$ lengthed `std::vector<std::int64_t>` of values (s_0, s_1, \dots, s_d) .

The offset is counted in elements of the data type (complex or real) defined by the descriptor configuration as tabulated below.

The computation functions take containers(`sync1::buffer` or USM pointer) which are typed according to the descriptor configuration parameters. Specifically, the *forward domain* which defines the type of transformation and the *storage format* configuration parameters: `config_param::COMPLEX_STORAGE`, `config_param::REAL_STORAGE` and `config_param::CONJUGATE_EVEN_STORAGE` define the type of the elements as shown here:

Assumed Element Types using complex-to-complex transform and `config_param::COMPLEX_STORAGE`:

COMPLEX_STORAGE	Element type of forward data	Element type of backward data
<i>COMPLEX_COMPLEX</i>	Complex	Complex
<i>REAL_REAL</i>	Real	Real

Assumed Element Types using real-to-complex transform and `config_param::REAL_STORAGE`:

REAL_STORAGE	Element type of forward data	Element type of backward data
<i>REAL_REAL</i>	Real	Real

Assumed Element Types using real-to-complex transform and `config_param::CONJUGATE_EVEN_STORAGE`:

CONJUGATE_EVEN_STORAGE	Element type of forward data	Element type of backward data
<i>COMPLEX_COMPLEX</i>	Real	Complex

The `config_param::INPUT_STRIDES` configuration parameter defines the layout of the input data, while the element type is defined by the forward domain for the *compute_forward* function and by the backward domain for the *compute_backward* function. The `config_param::OUTPUT_STRIDES` configuration parameter defines the layout of the output data, while the element type is defined by the backward domain for the *compute_forward* function and by the forward domain for *compute_backward* function.

For in-place transforms (`config_param::PLACEMENT=config_value::INPLACE`), the configuration set by `config_param::OUTPUT_STRIDES` is ignored when the element types in the forward and backward domains are the same. If they are different, set `config_param::OUTPUT_STRIDES` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the first elements on input and output must coincide in each dimension.

Parent topic *Configuration Parameters and Enums*

FORWARD_DISTANCE and BACKWARD_DISTANCE

The FFT interface enables computation of multiple transforms. To compute multiple transforms, you need to specify the data distribution of the multiple sets of data. The distance between the first data elements of consecutive data sets, FORWARD_DISTANCE for forward *domain* data or BACKWARD_DISTANCE for backward *domain* data, specifies the distribution. The configuration setting is a value of `std::int64_t` data type.

The default value for both configuration settings is one. You must set this parameter explicitly if the number of transforms is greater than one (see *Number of Transforms*).

The distance is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the *domain* template parameter, and the COMPLEX_STORAGE, REAL_STORAGE and CONJUGATE_EVEN_STORAGE configuration parameters described in *Storage Formats* define the type of the elements as shown in the *complex_storage*, *real_storage* and *conjugate_even_storage* tables.

For in-place transforms (`PLACEMENT=INPLACE`), the configuration set by FORWARD_DISTANCE and BACKWARD_DISTANCE should be consistent, that is, the locations of the data sets for input and output must coincide.

Parent topic: *Configuration Parameters and Enums*

descriptor

The descriptor class defines a discrete Fourier transform problem to be computed.

Description

The discrete Fourier transform problem is defined through the use of the `oneapi::mkl::dft::descriptor` class which lives in the `oneapi::mkl::dft::` namespace. The enum and `config_param` values associated with the descriptor class can be found in *Configuration Parameters and Enums* including *precision*, *domain* and *config_param*. The descriptor class allows to set several configuration parameters using `set_value` (and query using `get_value`) and then upon call to `commit` with a `ycl::queue`, is ready to be used in computations on the specified device.

This class is then passed to a `compute_forward` or `compute_backward` function along with the data for the actual transformation to be applied.

Note: The `compute_forward` and `compute_backward` functions may need to be able to access the internals of the descriptor to apply the transform, this could be done for instance, by labeling them as friend functions of the descriptor class.

descriptor class

Syntax

The descriptor class lives in the `oneapi::mkl::dft` namespace.

```
namespace oneapi::mkl::dft {
    template <oneapi::mkl::dft::precision prec, oneapi::mkl::dft::domain dom>
    class descriptor {
    public:
        // Syntax for 1-dimensional DFT
        descriptor(std::int64_t length);

        // Syntax for d-dimensional DFT
        descriptor(std::vector<std::int64_t> dimensions);

        ~descriptor();

        void set_value(config_param param, ...);
        void get_value(config_param param, ...);
        void commit(sycl::queue &queue);
    };
}
```

Descriptor class template parameters

precision **prec** Specifies the floating-point precision in which the transform is to be carried out.

domain **dom** Specifies the forward domain for the transformations.

Descriptor class member functions

Routines	Description
<i>constructors</i>	Initialize descriptor for 1-dimensional or N-dimensional transformations
<i>set_value</i>	Sets one particular configuration parameter with the specified configuration value.
<i>get_value</i>	Gets the configuration value of one particular configuration parameter.
<i>commit</i>	Performs all initialization for the actual FFT computation.

Descriptor class constructors

The constructors for the discrete Fourier transform `descriptor` class with default configuration settings for a given precision, forward *domain* type and dimension of the transform.

The constructors allocate memory for the descriptor data structure and instantiate it with all the default configuration settings for the precision, (forward) *domain*, and dimensions of the transform. The constructors do not perform any significant computational work, such as computation of twiddle factors. The function *commit* does this work after use of the function *set_value* to set values of all necessary parameters.

Syntax (one-dimensional transform)

```
namespace oneapi::mkl::dft {

    template <oneapi::mkl::dft::precision prec, oneapi::mkl::dft::domain dom>
    descriptor<prec,dom>(std::int64_t length);

}
```

Syntax (multi-dimensional transform)

```
namespace oneapi::mkl::dft {

    template <oneapi::mkl::dft::precision prec, oneapi::mkl::dft::domain dom>
    descriptor<prec,dom>(std::vector<std::int64_t> dimensions);

}
```

Input Parameters

length dimension(length) of data for a 1-dimensional transform.

dimensions vector of $d \geq 0$ dimensions(lengths) of data for a d-dimensional transform.

Throws

The *descriptor()* constructor shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here:

oneapi::mkl::host_bad_alloc() If any memory allocations on host have failed, for instance due to insufficient memory.

oneapi::mkl::unimplemented() If length of dimensions vector is larger than is supported by the library implementation.

Descriptor class member table: *Descriptor class member functions*

set_value

Sets DFT configuration values before *commit*.

Description

This function sets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see *config_param*. All calls to *set_param* must be done before *commit*.

Syntax

```

namespace oneapi::mkl::dft {

    template <oneapi::mkl::dft::precision prec, oneapi::mkl::dft::domain dom>
    void descriptor<prec,dom>::set_value(config_param param, ...);

}

```

Input Parameters

param The enum value of *config_param* to be set.

... The corresponding value or container corresponding to the specific parameter. Defined in *config_param*.

Throws

The *descriptor::set_value()* routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here:

oneapi::mkl::invalid_argument() If the provided *config_param* or *config_value* is not valid.

oneapi::mkl::unimplemented() If the provided *config_param* or *config_value* is valid, but not supported by the library implementation.

Descriptor class member table: *Descriptor class member functions*

get_value

Retrieves current DFT configuration values.

Description

This function gets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see *config_param*.

Syntax

```
namespace oneapi::mkl::dft {

    template <oneapi::mkl::dft::precision prec, oneapi::mkl::dft::domain dom>
    void descriptor<prec,dom>::get_value(config_param param, ...);

}
```

Input Parameters

param The enum value of *config_param* to be retrieved.

... The corresponding value or container corresponding to the specific parameter. Defined in *config_param*.

Throws

The *descriptor::get_value()* routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here:

oneapi::mkl::invalid_argument() If the requested *config_param* is not correct.

Descriptor class member table: *Descriptor class member functions*

commit

Finalizes DFT descriptor after all configuration parameters have been set.

Description

This function completes initialization of a previously created descriptor, which is required before the descriptor can be used for FFT computations. Typically, committing the descriptor performs all initialization that is required for the actual FFT computation on the device specified through input queue. The initialization performed by the function may involve exploring different factorizations of the input length to find the optimal computation method.

All calls to the *set_value* function to change configuration parameters of a descriptor need to happen after the constructor call for the *descriptor* class and before a call to *commit*. Typically, a commit function call is immediately followed by a computation function call (see *compute_forward* or *compute_backward*)

Syntax

```
namespace oneapi::mkl::dft {
    template <oneapi::mkl::dft::precision prec, oneapi::mkl::dft::domain dom>
    void descriptor<prec,dom>::commit(sycl::queue& queue);
}
```

Input Parameters

queue Valid DPC++ queue specifying the device and context on which the transformation will be executed.

Throws

The following oneMKL exceptions may be thrown in this function:

The `descriptor::commit()` routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here:

oneapi::mkl::invalid_argument() If the queue is found to be invalid in any way.

oneapi::mkl::host_bad_alloc() If any host side only memory allocations fail, for instance due to lack of memory.

oneapi::mkl::device_bad_alloc() If any device or shared memory allocation fail.

Descriptor class member table: *Descriptor class member functions*

Parent topic: *Discrete Fourier Transform Functions*

compute_forward

This function computes the forward transform defined by an instantiation of the *descriptor* class.

Description

The `compute_forward` function accepts the *descriptor* and one or more data parameters and in the case of USM data, any `sycl::event` dependencies. Given a successfully configured and committed descriptor, this function computes the forward transform, that is, the *transform* with the minus sign, $\delta = -1$, in the exponent.

The configuration parameters `config_param::COMPLEX_STORAGE`, `config_param::REAL_STORAGE` and `config_param::CONJUGATE_EVEN_STORAGE` define the layout of the input and output data and must be properly set in a call to *set_value*.

Note: The `compute_forward` function may need to access the internals and private/protected members of the *descriptor* class. This could be done, for instance, by labeling it as a friend function to the descriptor class.

compute_forward (Buffer version)**Syntax (In-place transform)**

```

namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename data_type>
    void compute_forward( descriptor_type      &desc,
                        sycl::buffer<data_type, 1> &inout);

}

```

Syntax (In-place transform, using config_param::COMPLEX_STORAGE=config_value::REAL_REAL data format)

```

namespace oneapi::mkl::dft {

    template <typename descriptor_type typename data_type>
    void compute_forward( descriptor_type      &desc,
                        sycl::buffer<data_type, 1> &inout_re,
                        sycl::buffer<data_type, 1> &inout_im);

}

```

Syntax (Out-of-place transform)

```

namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename input_type, typename output_type>
    void compute_forward( descriptor_type      &desc,
                        sycl::buffer<input_type, 1> &in,
                        sycl::buffer<output_type, 1> &out);

}

```

Syntax (Out-of-place transform, using config_param::COMPLEX_STORAGE=config_value::REAL_REAL data format)

```

namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename input_type, typename output_type>
    void compute_forward( descriptor_type      &desc,
                        sycl::buffer<input_type, 1> &in_re,
                        sycl::buffer<input_type, 1> &in_im,
                        sycl::buffer<output_type, 1> &out_re,
                        sycl::buffer<output_type, 1> &out_im);

}

```

Input Parameters

- desc** A fully configured and committed discrete Fourier transform descriptor class object, defining the type of transformation and data layout to be applied. At commit time, the `sycl::queue` has already been provided.
- inout** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house both the input and output data sequences for the in-place transformation. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- inout_re** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- inout_im** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- in** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the input data sequence for the out-of-place transformation. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- in_re** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of input data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- in_im** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of input data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

Output Parameters

- inout** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house both the input and output data sequences for the in-place transformation. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- inout_re** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- inout_im** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- out** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the output data sequence for the out-of-place transformation. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

out_re Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of output data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

out_im Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of output data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

Throws

The `oneapi::mkl::dft::compute_forward` routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here:

`oneapi::mkl::invalid_argument()` If the provided *descriptor* class is invalid, for instance, if it is a nullptr or if the value of `config_param::COMMIT_STATUS` in *descriptor* is not `config_param::COMMITTED`.

compute_forward (USM version)

Syntax (In-place transform)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename data_type>
    sycl::event compute_forward( descriptor_type           &desc,
                               data_type                *inout,
                               const std::vector<cl::sycl::event> &
    ↪dependencies = {});
}
```

Syntax (In-place transform, using `config_param::COMPLEX_STORAGE=config_value::REAL_REAL` data format)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename data_type>
    sycl::event compute_forward(descriptor_type           &desc,
                               data_type                *inout_re,
                               data_type                *inout_im,
                               const std::vector<cl::sycl::event> &
    ↪dependencies = {});
}
```

Syntax (Out-of-place transform)

```

namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename input_type, typename output_type>
    sycl::event compute_forward( descriptor_type          &desc,
                               input_type              *in,
                               output_type             *out,
                               const std::vector<cl::sycl::event> &
    ↪dependencies = {});
}

```

Syntax (Out-of-place transform, using config_param::COMPLEX_STORAGE=config_value::REAL_REAL data format)

```

namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename input_type, typename output_type>
    sycl::event compute_forward( descriptor_type          &desc,
                               input_type              *in_re,
                               input_type              *in_im,
                               output_type             *out_re,
                               output_type             *out_im,
                               const std::vector<cl::sycl::event> &
    ↪dependencies = {});
}

```

Input Parameter

desc A fully configured and committed discrete Fourier transform descriptor class object, defining the type of transformation and data layout to be applied. At commit time, the `sycl::queue` has already been provided.

inout USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house both the input and output data sequences for the in-place transformation. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_re USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_im USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

in USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the input data sequence for the out-of-place transformation. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

in_re USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of the input data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

in_im USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of the input data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

dependencies A vector of `sycl::event`'s that represent the previously enqueued tasks that must be finished before this transformation can be started.

Output Parameters

inout USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house both the input and output data sequences for the in-place transformation. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_re USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_im USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

out USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the output data sequence for the out-of-place transformation. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

out_re USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of the output data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

out_im USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of the output data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

Throws

The `oneapi::mkl::dft::compute_forward()` routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here:

`oneapi::mkl::invalid_argument()` If the provided *descriptor* class is invalid, for instance, if it is a nullptr or if the value of `config_param::COMMIT_STATUS` in *descriptor* is not `config_param::COMMITTED`. It will also be thrown if the input/output pointers are NULL.

Return Values

This function returns a `sycl::event` that allows to track progress of this transformation, and can be passed as a dependency to other routines that may depend on the results of this transformation to be finished before proceeding with the other operations.

Parent topic: *Discrete Fourier Transform Functions*

compute_backward

This function computes the backward transform defined by an instantiation of the *descriptor* class.

Description

The `compute_backward` function accepts the *descriptor* and one or more data parameters and in the case of USM data, any `sycl::event` dependencies. Given a successfully configured and committed descriptor, this function computes the backward transform, that is, the *transform* with the plus sign, $\delta = +1$, in the exponent.

The configuration parameters `config_param::COMPLEX_STORAGE`, `config_param::REAL_STORAGE` and `config_param::CONJUGATE_EVEN_STORAGE` define the layout of the input and output data and must be properly set in a call to *set_value*.

Note: The `compute_backward` function may need to access the internals and private/protected members of the *descriptor* class. This could be done, for instance, by labeling it as a friend function to the descriptor class.

compute_backward (Buffer version)

Syntax (In-place transform)

```
namespace oneapi::mkl::dft {
    template <typename descriptor_type, typename data_type>
    void compute_backward( descriptor_type      &desc,
                          sycl::buffer<data_type, 1> &inout );
}
```

Syntax (In-place transform, using `config_param::COMPLEX_STORAGE=config_value::REAL_REAL` data format)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename data_type>
    void compute_backward( descriptor_type          &desc,
                          sycl::buffer<data_type, 1> &inout_re,
                          sycl::buffer<data_type, 1> &inout_im);

}
```

Syntax (Out-of-place transform)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename input_type, typename output_type>
    void compute_backward( descriptor_type          &desc,
                          sycl::buffer<input_type, 1> &in,
                          sycl::buffer<output_type, 1> &out);

}
```

Syntax (Out-of-place transform, using `config_param::COMPLEX_STORAGE=config_value::REAL_REAL` data format)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename input_type, typename output_type>
    void compute_backward( descriptor_type          &desc,
                          sycl::buffer<input_type, 1> &in_re,
                          sycl::buffer<input_type, 1> &in_im,
                          sycl::buffer<output_type, 1> &out_re,
                          sycl::buffer<output_type, 1> &out_im);

}
```

Input Parameters

desc A fully configured and committed discrete Fourier transform descriptor class object, defining the type of backward transformation and data layout to be applied. At commit time, the `sycl::queue` has already been provided.

inout Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house both the input and output data sequences for the in-place transformation. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_re Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

- inout_im** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- in** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the input data sequence for the out-of-place transformation. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- in_re** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of input data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- in_im** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of input data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

Output Parameters

- inout** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house both the input and output data sequences for the in-place transformation. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- inout_re** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- inout_im** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- out** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the output data sequence for the out-of-place transformation. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- out_re** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of output data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.
- out_im** Sycl buffer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of output data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

Throws

The `oneapi::mkl::dft::compute_backward()` routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here:

`oneapi::mkl::invalid_argument()` If the provided `descriptor` class is invalid, for instance, if it is a nullptr or if the value of `config_param::COMMIT_STATUS` in `descriptor` is not `config_param::COMMITTED`.

compute_backward (USM version)

Syntax (In-place transform)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename data_type>
    sycl::event compute_backward( descriptor_type          &desc,
                               data_type                *inout,
                               const std::vector<cl::sycl::event> &
    ↪dependencies = {});
}
```

Syntax (In-place transform, using `config_param::COMPLEX_STORAGE=config_value::REAL_REAL` data format)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename data_type>
    sycl::event compute_backward(descriptor_type          &desc,
                               data_type                *inout_re,
                               data_type                *inout_im,
                               const std::vector<cl::sycl::event> &
    ↪dependencies = {});
}
```

Syntax (Out-of-place transform)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename input_type, typename output_type>
    sycl::event compute_backward( descriptor_type          &desc,
                               input_type                *in,
                               output_type               *out,
                               const std::vector<cl::sycl::event> &
    ↪dependencies = {});
}
```

Syntax (Out-of-place transform, using `config_param::COMPLEX_STORAGE=config_value::REAL_REAL` data format)

```
namespace oneapi::mkl::dft {

    template <typename descriptor_type, typename input_type, typename output_type>
    sycl::event compute_backward( descriptor_type          &desc,
                                input_type              *in_re,
                                input_type              *in_im,
                                output_type             *out_re,
                                output_type             *out_im,
                                const std::vector<cl::sycl::event> &
    ↪dependencies = {});

}

```

Input Parameters

desc A fully configured and committed discrete Fourier transform descriptor class object, defining the type of backward transformation and data layout to be applied. At commit time, the `sycl::queue` has already been provided.

inout USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house both the input and output data sequences for the in-place transformation. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_re USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_im USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

in USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the input data sequence for the out-of-place transformation. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

in_re USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of the input data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

in_im USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of the input data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

dependencies A vector of `sycl::event`'s that represent the previously enqueued tasks that must be finished before this transformation can be started.

Output Parameters

inout USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house both the input and output data sequences for the in-place transformation. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_re USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

inout_im USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of both the input and output data sequences for the in-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::INPLACE` for the configuration parameter `config_param::PLACEMENT`.

out USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the output data sequence for the out-of-place transformation. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

out_re USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the real part of the output data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

out_im USM pointer containing an array of length no less than is specified at the *descriptor construction* time to house the imaginary part of the output data sequence for the out-of-place transformation when using the `config_value::REAL_REAL` format for the `config_param::COMPLEX_STORAGE` configuration parameter. Corresponds to the choice of `config_value::NOT_INPLACE` for the configuration parameter `config_param::PLACEMENT`.

Throws

The `oneapi::mkl::dft::compute_backward()` routine shall throw the following exceptions if the associated condition is detected. An implementation may throw additional implementation-specific exception(s) in case of error conditions not covered here:

`oneapi::mkl::invalid_argument()` If the provided *descriptor* class is invalid, for instance, if it is a nullptr or if the value of `config_param::COMMIT_STATUS` in descriptor is not `config_param::COMMITTED`. It will also be thrown if the input/output pointers are NULL.

Return Values

This function returns a `sycl::event` that allows to track progress of this transformation, and can be passed as a dependency to other routines that may depend on the results of this transformation to be finished before proceeding with the other operations.

Parent topic: *Discrete Fourier Transform Functions*

11.2.4 Random Number Generators

The oneAPI Math Kernel Library Random Number Generators provides a *set of routines* implementing commonly used *pseudorandom, quasi-random, and non-deterministic generators* with *continuous and discrete distributions*.

Random Number Generators (RNG)

Definitions

The pseudo-random number generator is defined by a structure (S, μ, f, U, g) , where:

- S is a finite set of states (the state space)
- μ is a probability distribution on S for the initial state (or seed) s_0
- $f : S \rightarrow S$ is the transition function
- U – a finite set of output symbols
- $g : S \rightarrow U$ an output function

The generation of random numbers is as follows:

1. Generate the initial state (called the seed) s_0 according to μ and compute $u_0 = g(s_0)$.
2. Iterate for $i = 1, \dots$, and $u_i = g(s_i)$. Output values u_i are the so-called random numbers produced by the PRNG.

In computational statistics, random variate generation is usually made in two steps:

1. Generating imitations of independent and identically distributed (i.i.d.) random variables having the uniform distribution over the interval $(0, 1)$
2. Applying transformations to these i.i.d. $U(0, 1)$ random variates in order to generate (or imitate) random variates and random vectors from arbitrary distributions.

Structure

RNG domain contains two classes types:

- Engines (basic random number generators) classes, which holds the state of generator and is a source of i.i.d. random. Refer to *Engines (Basic Random Number Generators)* for a detailed description.
- Distribution classes templates (transformation classes) for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These classes contain all of the distribution's parameters (including generation method). Refer to *Distributions* for a detailed description of the distributions.

The RNG domain also contains two types of free functions:

- Generation routines. The current routines are used to obtain random numbers from a given engine with proper statistics defined by a given distribution. Refer to the *Generate Routine* section for a detailed description.
- Service routines. The routines are used to modify the engine state. Refer to *Service Routines* for a description of these routines.

Engine classes work with both generation and service routines. Distribution classes are used in generation routines only. Refer to the *oneMKL RNG Usage Model* section for the description of typical RNG scenario.

oneMKL RNG Usage Model

Description

A typical algorithm for random number generators is as follows:

1. Create and initialize the object for basic random number generator.
 - Use the `skip_ahead` or `leapfrog` function if it is required (used in parallel with random number generation for Host and CPU devices).
2. Create and initialize the object for distribution generator.
3. Call the generate routine to get random numbers with appropriate statistical distribution.

The following example demonstrates generation of random numbers that is output of basic generator (engine) PHILOX4X32X10. The seed is equal to 777. The generator is used to generate 10,000 normally distributed random numbers with parameters $\mu = 5$ and $\sigma = 2$. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

Buffer-based example

```
#include <iostream>
#include <vector>

#include "CL/sycl.hpp"
#include "oneapi/mkl/rng.hpp"

int main() {
    sycl::queue queue;
    const size_t n = 10000;
    const std::uint64_t seed = 777;
    std::vector<double> r(n);

    oneapi::mkl::rng::philox4x32x10 engine(queue, seed); // basic random number
    ↪generator object
    oneapi::mkl::rng::gaussian<double, oneapi::mkl::rng::gaussian_method::box_muller2>
    ↪distr(5.0, 2.0); // distribution object

    {
        //create buffer for random numbers
        sycl::buffer<double, 1> r_buf(r.data(), r.size());
        oneapi::mkl::rng::generate(distr, engine, n, r_buf); // perform generation
    }

    double s = 0.0;
    for(int i = 0; i < n; i++) {
        s += r[i];
    }
    s /= n;

    std::cout << "Average = " << s << std::endl;
    return 0;
}
```

USM-based example

```

#include <iostream>
#include <vector>

#include "CL/sycl.hpp"
#include "oneapi/mkl/rng.hpp"

int main() {
    sycl::queue queue;
    const size_t n = 10000;
    const std::uint64_t seed = 777;

    // create USM allocator
    sycl::usm_allocator<double, sycl::usm::alloc::shared> allocator(queue.get_context(),
↳queue.get_device());

    // create vector with USM allocator
    std::vector<double, decltype(allocator)> r(n, allocator);

    oneapi::mkl::rng::philox4x32x10 engine(queue, seed); // basic random number
↳generator object
    oneapi::mkl::rng::gaussian<double, oneapi::mkl::rng::gaussian_method::box_muller2>
↳distr(5.0, 2.0); // distribution object

    auto event = oneapi::mkl::rng::generate(distr, engine, n, r.data()); // perform
↳generation
    // sycl::event object is returned by generate function for synchronization
    event.wait(); // synchronization can be also done by queue.wait()

    double s = 0.0;
    for(int i = 0; i < n; i++) {
        s += r[i];
    }
    s /= n;

    std::cout << "Average = " << s << std::endl;
    return 0;
}

```

USM usage

You can also use USM with raw pointers by using the `sycl::malloc_shared/malloc_device` functions.

Parent topic: *Random Number Generators*

Generate Routine

- *generate* Entry point to obtain random numbers from a given engine with proper statistics of a given distribution.

Parent topic: *Random Number Generators*

generate

Entry point to obtain random numbers from a given engine with proper statistics of a given distribution.

Description and Assumptions

oneapi::mkl::rng::generate function produces random numbers sequence from the given engine object and applied transformation from a given distribution object.

generate (Buffer version)

Syntax

```
namespace oneapi::mkl::rng {
template<typename DistrType, typename EngineType>
void generate (const DistrType& distr, EngineType& engine, std::int64_t n, sycl::buffer
↳<typename DistrType::result_type, 1>& r);
}
```

Template Parameters

DistrType Type of distribution which is used for random number generation.

EngineType Type of engine which is used for random number generation.

Input Parameters

distr Distribution object. See *Distributions* for details.

engine Engine object. See *Engines (Basic Random Number Generators)* for details.

n Number of random values to be generated.

Output Parameters

r sycl::buffer of generated values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $n > r.get_count()$, or $n < 0$

generate (USM version)

Syntax

```

namespace oneapi::mkl::rng {
template<typename DistrType, typename EngineType>
sycl::event generate (const DistrType& distr, EngineType& engine, std::int64_t n,
↳ typename DistrType::result_type* r, const std::vector<sycl::event> & dependencies);
}

```

Template Parameters

DistrType Type of distribution which is used for random number generation.

EngineType Type of engine which is used for random number generation.

Input Parameters

distr Distribution object. See *Distributions* for details.

engine Engine object. See *Engines (Basic Random Number Generators)* for details.

n Number of random values to be generated.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

r pointer to generated values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $r == nullptr$, or $n < 0$

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Generate Routine*

Engines (Basic Random Number Generators)

oneMKL RNG provides pseudorandom, quasi-random, and non-deterministic random number generators for Data Parallel C++:

Routine	Description
<i>default_engine</i>	The default random engine
<i>mrg32k3a</i>	The combined multiple recursive pseudorandom number generator MRG32k3a [L'Ecuyer99a]
<i>philox4x32x10</i>	Philox4x32-10 counter-based pseudorandom number generator with a period of 2^{128} [Salmon11]
<i>mcg31m1</i>	The 31-bit multiplicative congruential pseudorandom number generator MCG(1132489760, 231 -1) [L'Ecuyer99]
<i>r250</i>	The 32-bit generalized feedback shift register pseudorandom number generator GFSR(250, 103) [Kirkpatrick81]
<i>mcg59</i>	The 59-bit multiplicative congruential pseudorandom number generator MCG(13^{13} , 2^{59}) from NAG Numerical Libraries [NAG]
<i>wichmann_hill</i>	Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [NAG]
<i>mt19937</i>	Mersenne Twister pseudorandom number generator MT19937 [Matsumoto98] with period length $2^{19937}-1$ of the produced sequence
<i>mt2203</i>	Set of 6024 Mersenne Twister pseudorandom number generators MT2203 [Matsumoto98], [Matsumoto00]. Each of them generates a sequence of period length equal to $2^{2203}-1$. Parameters of the generators provide mutual independence of the corresponding sequences.
<i>sfmt19937</i>	SIMD-oriented Fast Mersenne Twister pseudorandom number generator SFMT19937 [Saito08] with a period length equal to $2^{19937}-1$ of the produced sequence.
<i>sobol</i>	Sobol quasi-random number generator [Sobol76], [Bratley88], which works in arbitrary dimension.
<i>niederreiter</i>	Niederreiter quasi-random number generator [Bratley92], which works in arbitrary dimension.
<i>ars5</i>	ARS-5 counter-based pseudorandom number generator with a period of 2^{128} , which uses instructions from the AES-NI set ARS5 [Salmon11].
<i>non-deterministic</i>	Non-deterministic random number generator

For some basic generators, oneMKL RNG provides two methods of creating independent states in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo. The description of these functions can be found in the *Service Routines* section.

In addition, the MT2203 pseudorandom number generator is a set of 6024 generators designed to create up to 6024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

- *nondeterministic* Non-deterministic random number generator.

default_engine

Default random engine.

Description

The choice of engine type named by `default_engine` is implementation-defined. The implementation may select this type on the basis of performance, size, quality, or any combination of such factors.

type alias default_engine

Syntax

```
using default_engine = implementation-defined;
```

Parent topic: *Engines (Basic Random Number Generators)*

mrg32k3a

The combined multiple recursive pseudorandom number generator MRG32k3a.

Description

MRG32k3a engine is a 32-bit combined multiple recursive generator with two components of order 3 [L'Ecuyer99a]. MRG32k3a combined generator meets the requirements for modern RNGs, such as good multidimensional uniformity, or a long period ($p \approx 2^{191}$).

Generation algorithm

$$x_n = a_{11}x_{n-1} + a_{12}x_{n-2} + a_{13}x_{n-3} \pmod{m_1}$$

$$y_n = a_{21}y_{n-1} + a_{22}y_{n-2} + a_{23} \pmod{m_2}$$

$$z_n = x_n - y_n \pmod{m_1}$$

$$u_n = z_n / m_1$$

$$a_{11} = 0, a_{12} = 1403580, a_{13} = -810728, m_1 = 2^{32} - 209$$

$$a_{21} = 527612, a_{22} = 0, a_{23} = -1370589, m_2 = 2^{32} - 22853$$

class mrg32k3a

Syntax

```
namespace oneapi::mkl::rng {
class mrg32k3a {
public:
    static constexpr std::uint32_t default_seed = 1;

    mrg32k3a(sycl::queue queue, std::uint32_t seed = default_seed);

    mrg32k3a(sycl::queue queue, std::initializer_list<std::uint32_t> seed);

    mrg32k3a(const mrg32k3a& other);

    mrg32k3a(mrg32k3a&& other);

    mrg32k3a& operator=(const mrg32k3a& other);

    mrg32k3a& operator=(mrg32k3a&& other);

    ~mrg32k3a();
};
}
```

Class Members

Routine	Description
<code>sycl::queue queue, std::uint32_t seed = default_seed</code>	Constructor for common seed initialization of the engine
<code>mrg32k3a(sycl::queue queue, std::initializer_list<std::uint32_t> seed)</code>	Constructor for extended seed initialization of the engine
<code>mrg32k3a(const mrg32k3a& other)</code>	Copy constructor

<code>mrg32k3a& operator=(const mrg32k3a& other)</code>	Copy assignment operator
<code>mrg32k3a& operator=(mrg32k3a&& other)</code>	Move assignment operator

Constructors

```
mrg32k3a::sycl::queue queue, std::uint32_t seed = default_seed
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume $x_{-3} = seed \bmod m_1, x_{-2} = x_{-1} = y_{-3} = y_{-2} = y_{-1} = 1$.

```
mrg32k3a::mrg32k3a(sycl::queue queue, std::initializer_list<std::uint32_t> seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume if $n = 0 : x_{-3} = x_{-2} = x_{-1} = y_{-3} = y_{-2} = y_{-1} = 1$

if $n = 1 : x_{-3} = seed[0] \bmod m_1, x_{-2} = x_{-1} = y_{-3} = y_{-2} = y_{-1} = 1$

if $n = 2 : x_{-3} = seed[0] \bmod m_1, x_{-2} = seed[1] \bmod m_1, x_{-1} = y_{-3} = y_{-2} = y_{-1} = 1$

if $n = 3 : x_{-3} = seed[0] \bmod m_1, x_{-2} = seed[1] \bmod m_1, x_{-1} = seed[2] \bmod m_1$

$y_{-3} = y_{-2} = y_{-1} = 1$

if $n = 4 : x_{-3} = seed[0] \bmod m_1, x_{-2} = seed[1] \bmod m_1, x_{-1} = seed[2] \bmod m_1$

$y_{-3} = seed[3] \bmod m_2, y_{-2} = y_{-1} = 1$

if $n = 5 : x_{-3} = seed[0] \bmod m_1, x_{-2} = seed[1] \bmod m_1, x_{-1} = seed[2] \bmod m_1$

$y_{-3} = seed[3] \bmod m_2, y_{-2} = seed[4] \bmod m_2, y_{-1} = 1$

if $n \geq 6 : x_{-3} = seed[0] \bmod m_1, x_{-2} = seed[1] \bmod m_1, x_{-1} = seed[2] \bmod m_1$

$y_{-3} = seed[3] \bmod m_2, y_{-2} = seed[4] \bmod m_2, y_{-1} = seed[5] \bmod m_2$

if the values prove to be $x_{-3} = x_{-2} = x_{-1} = 0$, assume $x_{-3} = 1$

if the values prove to be $y_{-3} = y_{-2} = y_{-1} = 0$, assume $y_{-3} = 1$

```
mrg32k3a::mrg32k3a(const mrg32k3a& other)
```

Input Parameters

other Valid mrg32k3a object. The queue and state of the other engine is copied and applied to the current engine.

```
mrg32k3a::mrg32k3a(mrg32k3a&& other)
```

Input Parameters

other Valid mrg32k3a object. The queue and state of the other engine is moved to the current engine.

```
mrg32k3a::mrg32k3a& operator=(const mrg32k3a& other)
```

Input Parameters

other Valid mrg32k3a object. The queue and state of the other engine is copied and applied to the current engine.

```
mrg32k3a::mrg32k3a& operator=(mrg32k3a&& other)
```

Input Parameters

other Valid mrg32k3a r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

philox4x32x10

The Philox4x32x10 counter-based pseudorandom number generator.

Description

The Philox4x32x10 engine is a keyed family of generator of counter-based BRNG. The state consists of 128-bit integer counter c and two 32-bits keys k_0 and k_1 .

Generation algorithm

The generator has 32-bit integer output obtained in the following way [*Salmon11*]:

1. $c_n = c_{n-1} + 1$
2. $\omega_n = f(c_n)$, where f is a function that takes 128-bit argument and returns a 128-bit number. The returned number is obtained as follows:
 - 2.1. The argument c is interpreted as four 32-bit numbers $c = \overline{L_1R_1L_0R_0}$, where $\overline{ABCD} = A \cdot 2^{96} + B \cdot 2^{64} + C \cdot 2^{32} + D$, put $k_0^0 = k_0, k_1^0 = k_1$.
 - 2.2. The following recurrence is calculated:

$$L_1^{i+1} = \text{mullo}(R_1^i, 0xD2511F53)$$

$$R_1^{i+1} = \text{mulhi}(R_0^i, 0xCD9E8D57) \oplus k_0^i \oplus L_0^i$$

$$L_0^{i+1} = \text{mullo}(R_0^i, 0xCD9E8D57)$$

$$R_0^{i+1} = \text{mulhi}(R_1^i, 0xD2511F53) \oplus k_1^i \oplus L_1^i$$

$$k_0^{i+1} = k_0^i + 0xBB67AE85$$

$k_1^{i+1} = k_1^i + 0x9E3779B9$, where $\text{mulhi}(a, b)$ and $\text{mullo}(a, b)$ are high and low parts of the $a \cdot b$ product respectively.

2.3. Put $f(c) = \overline{L_1^N R_1^N L_0^N R_0^N}$, where $N = 10$

3. Integer output: $r_{4n+k} = \omega_n(k)$, where $\omega_n(k)$ is the k -th 32-bit integer in quadruple ω_n , $k = 0, 1, 2, 3$

4. Real output: $u_n = (\text{int})r_n/2^{32} + 1/2$

class philox4x32x10

Syntax

```
namespace oneapi::mkl::rng {
class philox4x32x10 {
public:
static constexpr std::uint64_t default_seed = 0;

philox4x32x10(sycl::queue queue, std::uint64_t seed = default_seed);

philox4x32x10(sycl::queue queue, std::initializer_list<std::uint64_t> seed);

philox4x32x10(const philox4x32x10& other);

philox4x32x10(philox4x32x10&& other);

philox4x32x10& operator=(const philox4x32x10& other);

philox4x32x10& operator=(philox4x32x10&& other);

~philox4x32x10();
};
}
```

Constructors

```
philox4x32x10::philox4x32x10(sycl::queue queue, std::uint64_t seed = default_seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume $k = seed, c = 0$, where k is a 64-bit key, c is a 128-bit counter.

```
philox4x32x10::philox4x32x10(sycl::queue queue, std::initializer_list<std::uint64_t>
↪seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume if $n = 0 : k = 0, c = 0$

if $n = 1 : k = seed[0], c = 0$

if $n = 2 : k = seed[0], c = seed[1]$

if $n = 3 : k = seed[0], c = seed[1] + seed[2] \cdot 2^{64}$

for $n > 3$ following arguments are ignored

```
philox4x32x10::philox4x32x10(const philox4x32x10& other)
```

Input Parameters

other Valid `philox4x32x10` object. The queue and state of the other engine is copied and applied to the current engine.

```
philox4x32x10::philox4x32x10(philox4x32x10&& other)
```

Input Parameters

other Valid `philox4x32x10` r-value object. The queue and state of the other engine is moved to the current engine.

```
philox4x32x10::philox4x32x10& operator=(const philox4x32x10& other)
```

Input Parameters

other Valid `philox4x32x10` object. The queue and state of the other engine is copied and applied to the current engine.

```
philox4x32x10::philox4x32x10& operator=(philox4x32x10&& other)
```

Input Parameters

other Valid `philox4x32x10` r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

mcg31m1

The 31-bit multiplicative congruential pseudorandom number generator MCG(1132489760, 231 -1).

Description

The `mcg31m1` engine is a 31-bit multiplicative congruential generator [L'Ecuyer99]. The `mcg31m1` generator belongs to linear congruential generators with the period length of approximately 2^{31} . Such generators are still used as default random number generators in various software systems, mainly due to the simplicity of the portable versions implementation, speed, and compatibility with the earlier systems versions. However, their period length does not meet the requirements for modern basic generators. Still, the `mcg31m1` generator possesses good statistic properties and you may successfully use it to generate random numbers of different distributions for small samplings.

Generation algorithm

$$x_n = ax_{n-1}(\text{mod } m)$$

$$u_n = x_n/m$$

$$a = 1132489760, m = 2^{31} - 1$$

class mcg31m1

Syntax

```
namespace oneapi::mkl::rng {
class mcg31m1 {
public:
    static constexpr std::uint32_t default_seed = 1;

    mcg31m1(sycl::queue queue, std::uint32_t seed = default_seed);

    mcg31m1(const mcg31m1& other);

    mcg31m1(mcg31m1&& other);

    mcg31m1& operator=(const mcg31m1& other);
```

(continues on next page)

<code>mcg59(mcg59&& other)</code>	Move constructor
<code>mcg59& operator=(const mcg59& other)</code>	Copy assignment operator
<code>mcg59& operator=(mcg59&& other)</code>	Move assignment operator

Constructors

```
mcg59::mcg59(sycl::queue queue, std::uint64_t seed = default_seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume $x_0 = seed \bmod 2^{59}$, if $x_0 = 0$, assume $x_0 = 1$.

```
mcg59::mcg59(const mcg59& other)
```

Input Parameters

other Valid `mcg59` object. The queue and state of the other engine is copied and applied to the current engine.

```
mcg59::mcg59(mcg59&& other)
```

Input Parameters

other Valid `mcg59` object. The queue and state of the other engine is moved to the current engine.

```
mcg59::mcg59& operator=(const mcg59& other)
```

Input Parameters

other Valid mcg59 object. The queue and state of the other engine is copied and applied to the current engine.

```
mcg59::mcg59& operator=(mcg59&& other)
```

Input Parameters

other Valid mcg59 r-value object. The queue and state of the other engine is moved to the current engine.

r250

The 32-bit generalized feedback shift register pseudorandom number generator GFSR(250,103) [*Kirkpatrick81*].

Description

Feedback shift register generators possess ample theoretical foundation and were initially intended for cryptographic and communication applications. The stream state is the array of 250 32-bit integers.

Generation algorithm

$$x_n = x_{n-103} \oplus x_{n-250}$$

$$u_n = x_n / 2^{32}$$

class r250

Syntax

```
namespace oneapi::mkl::rng {
class r250 {
public:
    static constexpr std::uint32_t default_seed = 1;

    r250(sycl::queue queue, std::uint32_t seed = default_seed);

    r250(sycl::queue queue, std::vector<std::uint32_t> seed);

    r250(const r250& other);

    r250(r250&& other);

    r250& operator=(const r250& other);
```

(continues on next page)

(continued from previous page)

```

r250& operator=(r250&& other);

~r250();
};
}

```

Class Members

Routine	Description
<i>r250(sycl::queue queue, std::uint32_t seed = default_seed)</i>	Constructor for common seed initialization of the engine
<i>r250(sycl::queue queue, std::vector<std::uint32_t> seed)</i>	Constructor for extended seed initialization of the engine
<i>r250(const r250& other)</i>	Copy constructor
<i>r250(r250&& other)</i>	Move constructor
<i>r250& operator=(const r250& other)</i>	Copy assignment operator
<i>r250& operator=(r250&& other)</i>	Move assignment operator

Constructors

```
r250::r250(sycl::queue queue, std::uint32_t seed = default_seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume $x_{-250} = seed$. If $seed = 0$, assume $seed = 1$. Other values in state are initialized according to recurrent correlation $x_{n+1} = 69069x_n \pmod{2^{32}}$. Then the values $x_{7k-247}, k = 0, 1, \dots, 31$ are interpreted as a binary matrix of size 32×32 and diagonal bits are set to 0, the under-diagonal bits to 0.

```
r250::r250(sycl::queue queue, std::vector<std::uint32_t> seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state if $n \geq 0 : x_{k-250} = seed[k], k = 0, 1, \dots, 249$

```
r250::r250(const r250& other)
```

Input Parameters

other Valid `r250` object. The queue and state of the other engine is copied and applied to the current engine.

```
r250::r250(r250&& other)
```

Input Parameters

other Valid `r250` object. The queue and state of the other engine is moved to the current engine.

```
r250::r250& operator=(const r250& other)
```

Input Parameters

other Valid `r250` object. The queue and state of the other engine is copied and applied to the current engine.

```
r250::r250& operator=(r250&& other)
```

Input Parameters

other Valid `r250` r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

wichmann_hill

The `wichmann_hill` engine is the set of 273 Wichmann-Hill's combined multiplicative congruential generators from NAG Numerical Libraries [NAG].

Description

The set of 372 different basic pseudorandom number generators `wichmann_hill` is the second basic generator in the NAG libraries.

Generation algorithm

$$x_n = a_{1,j}x_{n-1} \pmod{m_{1,j}}$$

$$y_n = a_{2,j}y_{n-1} \pmod{m_{2,j}}$$

$$z_n = a_{3,j}z_{n-1} \pmod{m_{3,j}}$$

$$w_n = a_{4,j}w_{n-1} \pmod{m_{4,j}}$$

$$u_n = (x_n/m_{1,j} + y_n/m_{2,j} + z_n/m_{3,j} + w_n/m_{4,j}) \pmod{1}$$

The constants $a_{i,j}$ range from 112 to 127, the constants $m_{i,j}$ are prime numbers ranging from 16718909 to 16776917, close to 2^{24} .

class wichmann_hill**Syntax**

```

namespace oneapi::mkl::rng {
class wichmann_hill {
public:
    static constexpr std::uint32_t default_seed = 1;

    wichmann_hill(sycl::queue queue, std::uint32_t seed = default_seed);

    wichmann_hill(sycl::queue queue, std::uint32_t seed, std::uint32_t engine_idx);

    wichmann_hill(sycl::queue queue, std::initializer_list<std::uint32_t> seed);

    wichmann_hill(sycl::queue queue, std::initializer_list<std::uint32_t> seed,
↳std::uint32_t engine_idx);

    wichmann_hill(const wichmann_hill& other);

    wichmann_hill(wichmann_hill&& other);

    wichmann_hill& operator=(const wichmann_hill& other);

    wichmann_hill& operator=(wichmann_hill&& other);

    ~wichmann_hill();
};
}

```

Class Members

Routine	Description
<i>wichmann_hill(sycl::queue queue, std::uint32_t seed = default_seed)</i>	Constructor for common seed initialization of the engine (for this case multiple generators of the set would be used)
<i>wichmann_hill(sycl::queue queue, std::uint32_t seed, std::uint32_t engine_idx)</i>	Constructor for common seed initialization of the engine (for this case single generator of the set would be used)
<i>wichmann_hill(sycl::queue& queue, std::initializer_list<std::uint32_t> seed)</i>	Constructor for extended seed initialization of the engine (for this case multiple generators of the set would be used)
<i>wichmann_hill(sycl::queue& queue, std::initializer_list<std::uint32_t> seed, std::uint32_t engine_idx)</i>	Constructor for extended seed initialization of the engine (for this case single generator of the set would be used)

<i>wichmann_hill& operator=(const wichmann_hill& other)</i>	Copy assignment operator
<i>wichmann_hill& operator=(wichmann_hill&& other)</i>	Move assignment operator

Constructors

```
wichmann_hill::wichmann_hill(sycl::queue queue, std::uint32_t seed = default_seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state. Assume $x_0 = seed \bmod m_1$, $y_0 = z_0 = w_0 = 1$. If $x_0 = 0$, assume $x_0 = 1$.

```
wichmann_hill::wichmann_hill(sycl::queue queue, std::uint32_t seed, std::uint32_t engine_
↪idx)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state. Assume $x_0 = seed \bmod m_1$, $y_0 = z_0 = w_0 = 1$. If $x_0 = 0$, assume $x_0 = 1$.

engine_idx The index of the set 1, ..., 273.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $idx > 273$

```
wichmann_hill::wichmann_hill(sycl::queue& queue, std::initializer_list<std::uint32_t>
↪seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume: if $n = 0$: $x_0 = y_0 = z_0 = w_0 = 1$

if $n = 1$: $x_0 = seed[0] \bmod m_1$, $y_0 = z_0 = w_0 = 1$. If $x_0 = 0$, assume $x_0 = 1$.

if $n = 2$: $x_0 = seed[0] \bmod m_1$, $y_0 = seed[1] \bmod m_2$, $z_0 = w_0 = 1$.

if $n = 3$: $x_0 = seed[0] \bmod m_1$, $y_0 = seed[1] \bmod m_2$, $z_0 = seed[2] \bmod m_3$, $w_0 = 1$.

if $n \geq 4$: $x_0 = seed[0] \bmod m_1$, $y_0 = seed[1] \bmod m_2$

$z_0 = seed[2] \bmod m_3$, $w_0 = seed[3] \bmod m_4$.

```
wichmann_hill::wichmann_hill(sycl::queue& queue, std::initializer_list<std::uint32_t>
↪seed, std::uint32_t engine_idx)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume: if $n = 0 : x_0 = y_0 = z_0 = w_0 = 1$

if $n = 1 : x_0 = seed[0] \bmod m_1, y_0 = z_0 = w_0 = 1$. If $x_0 = 0$, assume $x_0 = 1$.

if $n = 2 : x_0 = seed[0] \bmod m_1, y_0 = seed[1] \bmod m_2, z_0 = w_0 = 1$.

if $n = 3 : x_0 = seed[0] \bmod m_1, y_0 = seed[1] \bmod m_2, z_0 = seed[2] \bmod m_3, w_0 = 1$.

if $n \geq 4 : x_0 = seed[0] \bmod m_1, y_0 = seed[1] \bmod m_2$

$z_0 = seed[2] \bmod m_3, w_0 = seed[3] \bmod m_4$.

engine_idx The index of the set $1, \dots, 273$.

```
wichmann_hill::wichmann_hill(const wichmann_hill& other)
```

Input Parameters

other Valid `wichmann_hill` object. The queue and state of the other engine is copied and applied to the current engine.

```
wichmann_hill::wichmann_hill(wichmann_hill&& other)
```

Input Parameters

other Valid `wichmann_hill` object. The queue and state of the other engine is moved to the current engine.

```
wichmann_hill::wichmann_hill& operator=(const wichmann_hill& other)
```

Input Parameters

other Valid `wichmann_hill` object. The queue and state of the other engine is copied and applied to the current engine.

```
wichmann_hill::wichmann_hill& operator=(wichmann_hill&& other)
```

Input Parameters

other Valid `wichmann_hill` r-value object. The queue and state of the other engine is moved to the current engine.

mt19937

Mersenne Twister pseudorandom number generator.

Description

The Mersenne Twister pseudorandom number generator, mt19937, is a modification of twisted generalized feedback shift register generator [Matsumoto98]. MT19937 has the period length of $2^{19937} - 1$ and is 623-dimensionally equidistributed with up to 32-bit accuracy. These properties make the generator applicable for simulations in various fields of science and engineering. The state of the generator is represented by 624 32-bit unsigned integer numbers.

Generation algorithm

$$x_n = x_{n-(624-397)} \oplus ((x_{n-624} \& 0x80000000) | (x_{n-624+1} \& 0x7FFFFFFF))A$$

$$y_n = x_n$$

$$y_n = y_n \oplus (y_n \gg 11)$$

$$y_n = y_n \oplus ((y_n \ll 7) \& 0x9D2C5680)$$

$$y_n = y_n \oplus ((y_n \ll 15) \& 0xEFC60000)$$

$$y_n = y_n \oplus (y_n \gg 18)$$

$$u_n = y_n / 2^{32}$$

Matrix $A_j(32 \times 32)$ has the following format:

$$\begin{bmatrix} 0 & 1 & 0 & \dots & \dots \\ 0 & 0 & \dots & 0 & \dots \\ \dots & \dots & \dots & \dots & \dots \\ 0 & \dots & 0 & 0 & 1 \\ a_{31} & a_{30} & \dots & \dots & a_0 \end{bmatrix}$$

Where the 32-bit vector $a = a_{31}..a_0$ has the value $a = 0x9908B0DF$.

class mt19937

Syntax

```

namespace oneapi::mkl::rng {
class mt19937 {
public:
    static constexpr std::uint32_t default_seed = 1;

    mt19937(sycl::queue queue, std::uint32_t seed = default_seed);

    mt19937(sycl::queue queue, std::initializer_list<std::uint32_t> seed);

```
mt19937::mt19937& operator=(mt19937&& other)
```

Input Parameters

other Valid mt19937 r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

sfmt19937

The SIMD-oriented Mersenne Twister pseudorandom number generator.

Description

SIMD-oriented Fast Mersenne Twister pseudorandom number generator SFMT19937 [Saito08] with a period length equal to $2^{19937} - 1$ of the produced sequence. The state of the engine contains the array of 156 128-bit integers.

Generation algorithm

$$w_n = w_0A \oplus w_M B \oplus w_{n-2}C \oplus w_{n-1}D$$

Where w_0, w_M, w_{n-2}, \dots are the 128-bit integers, and wA, wB, wC, wD operations are defined as follows:

$wA = (w \ll 8) \oplus w$, left shift of 128-bit integer w by a followed by exclusive-or operation

$wB = (w \gg 8) \& mask$, right shift of each 32-bit integer in quadruple w by and-operator with quadruple of 32-bit masks $mask = (0xBFFFFFFF6, 0xDFFAFFFF, 0xDDFECB7F, 0xDFFFFFFEF)$

$wC = (w \gg 8) \oplus w$, right shift of 128-bit integer w

$wD = (w \ll 8)$, left shift of each 32-bit integer in quadruple w

Integer output: $r_{4n+k} = w_n(k)$, where $w_n(k)$ is the k -th 32-bit integer in quadruple w_n , $k = 0, 1, 2, 3$

$$u_n = (int)r_n/2^{32} + 1/2$$

class sfmt19937**Syntax**

```

namespace oneapi::mkl::rng {
class sfmt19937 {
public:
    static constexpr std::uint32_t default_seed = 1;

other Valid `sfmt19937` r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

mt2203

The mt2203 engine is the set of 6024 Mersenne Twister pseudorandom number generators MT2203 [Matsumoto98], [Matsumoto00].

Description

The set of 6024 basic pseudorandom number generators MT2203 is a natural addition to the MT19937 generator. MT2203 generators are intended for use in large scale Monte Carlo simulations performed on multi-processor computer systems.

Generation algorithm

For $j = 1, \dots, 6024$:

$$x_{n,j} = x_{n-(69-34),j} \oplus ((x_{n-69,j} \& 0xFFFFFFFFE0) | (x_{n+69+1,j} \& 0x1F)) A_j$$

$$y_{n,j} = x_{n,j}$$

$$y_{n,j} = y_{n,j} \oplus (y_{n,j} \gg 12)$$

$$y_{n,j} = y_{n,j} \oplus ((y_{n,j} \ll 7) \& b_j)$$

$$y_{n,j} = y_{n,j} \oplus ((y_{n,j} \ll 15) \& c_j)$$

$$y_{n,j} = y_{n,j} \oplus (y_{n,j} \gg 18)$$

Matrix $A_j(32 \times 32)$ has the following format:

$$\begin{bmatrix} 0 & 1 & 0 & \dots & \dots \\ 0 & 0 & \dots & 0 & \dots \\ \dots & \dots & \dots & \dots & \dots \\ 0 & \dots & 0 & 0 & 1 \\ a_{31,j} & a_{30,j} & \dots & \dots & a_{0,1} \end{bmatrix}$$

class mt2203

<i>mt2203& operator=(mt2203&& other)</i>	Move assignment operator

Constructors

```
mt2203::mt2203(sycl::queue queue, std::uint32_t seed = default_seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state. The initialization algorithm described in [MT2203].

```
mt2203::mt2203(sycl::queue queue, std::uint32_t seed, std::uint32_t engine_idx)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state. The initialization algorithm described in [MT2203].

engine_idx The index of the set 1, ..., 6024.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `idx > 6024`

```
mt2203::mt2203(sycl::queue queue, std::initializer_list<std::uint32_t> seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state. The initialization algorithm described in [MT2203].

```
mt2203::mt2203(sycl::queue queue, std::initializer_list<std::uint32_t> seed, std::uint32_t engine_idx)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state. The initialization algorithm described in [MT2203].

engine_idx The index of the set 1, ..., 6024.

```
mt2203::mt2203(const mt2203& other)
```

Input Parameters

other Valid `mt2203` object. The queue and state of the other engine is copied and applied to the current engine.

```
mt2203::mt2203(mt2203&& other)
```

Input Parameters

other Valid mt2203 object. The queue and state of the other engine is moved to the current engine.

```
mt2203::mt2203& operator=(const mt2203& other)
```

Input Parameters

other Valid mt2203 object. The queue and state of the other engine is copied and applied to the current engine.

```
mt2203::mt2203& operator=(mt2203&& other)
```

Input Parameters

other Valid mt2203 r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

ars5

The ars5 counter-based pseudorandom number generator.

Description

The ars5 engine is a keyed family of counter-based BRNG. The state consists of a 128-bit integer counter c and a 128-bit key k . The BRNG is based on the AES encryption algorithm [FIPS-197].

Generation algorithm

The generator has a 32-bit integer output obtained in the following way [Salmon11]:

1. The i -th number is defined by the following formula $r_i = (f(i/4) \gg ((i \bmod 4) * 32)) \bmod 2^{32}$
2. **Function $f(c)$ takes a 128-bit argument and returns a 128-bit number. The returned number is obtained as follows:**
 - 2.1. $c_0 = c \oplus k$ and $k_0 = k$.
 - 2.2. The following recurrence is calculated $N = 5$ times:

$$c_{i+1} = \text{SubBytes}(c)$$

$$c_{i+1} = \text{ShiftRows}(c_{i+1})$$

$$c_{i+1} = \text{MixColumns}(c_{i+1}), \text{ this step is omitted if } i + 1 = N$$

$$c_{i+1} = \text{AddRoundKey}(c_{i+1}, k_j)$$

$$Lo(k_{i+1}) = Lo(k) + 0x9E3779B97F4A7C15$$

$$Hi(k_{i+1}) = Hi(k) + 0xBB67AE8584CAA73B$$
 Specification for *SubBytes*, *ShiftRows*, *MixColumns*, *AddRoundKey* functions can be found in [FIPS-197].
 - 2.3. Put $f(c) = c_N$, where $N = 10$
3. Real output: $u_n = (int)r_n/2^{32} + 1/2$

class ars5**Syntax**

```

namespace oneapi::mkl::rng {
class ars5 {
public:
    static constexpr std::uint64_t default_seed = 0;

    ars5(sycl::queue queue, std::uint64_t seed = default_seed);

    ars5(sycl::queue queue, std::initializer_list<std::uint64_t> seed);

    ars5(const ars5& other);

    ars5(ars5&& other);

    ars5& operator=(const ars5& other);

    ars5& operator=(ars5&& other);

    ~ars5();
};
}

```

Class Members

Routine	Description
<i>ars5(sycl::queue queue, std::uint64_t seed)</i>	Constructor for common seed initialization of the engine
<i>ars5(sycl::queue queue, std::initializer_list<std::uint64_t> seed)</i>	Constructor for extended seed initialization of the engine
<i>ars5(const ars5& other)</i>	Copy constructor
<i>ars5(ars5&& other)</i>	Move constructor
<i>ars5& operator=(const ars5& other)</i>	Copy assignment operator
<i>ars5& operator=(ars5&& other)</i>	Move assignment operator

Constructors

```
ars5::ars5(sycl::queue queue, std::uint64_t seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume $k = seed, c = 0$, where k is 128-bit key, c is 128-bit counter.

```
ars5::ars5(sycl::queue queue, std::initializer_list<std::uint64_t> seed)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

seed The initial conditions of the generator state, assume if $n = 0 : k = 0, c = 0$

if $n = 1 : k = seed[0], c = 0$

if $n = 2 : k = seed[0] + seed[1] \cdot 2^{64}, c = 0$

if $n = 3 : k = seed[0] + seed[1] \cdot 2^{64}, c = seed[2]$

if $n = 4 : k = seed[0] + seed[1] \cdot 2^{64}, c = seed[2] + seed[3] \cdot 2^{64}$

for $n > 4$ following arguments are ignored

```
ars5::ars5(const ars5& other)
```

Input Parameters

other Valid `ars5` object. The queue and state of the other engine is copied and applied to the current engine.

```
ars5::ars5(ars5&& other)
```

Input Parameters

other Valid `ars5` r-value object. The queue and state of the other engine is moved to the current engine.

```
ars5::ars5& operator=(const ars5& other)
```

Input Parameters

other Valid `ars5` object. The queue and state of the other engine is copied and applied to the current engine.

```
ars5::ars5& operator=(ars5&& other)
```

Input Parameters

other Valid `ars5` r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

sobol

The `sobol` is a 32-bit Gray code-based quasi-random number generator.

Description

Bratley and Fox [Bratley88] provide an implementation of the SOBOL quasi-random number generator. The default dimensions of quasi-random vectors can vary from 1 to 40 inclusive. It is also allowed to register user-defined parameters (direction numbers).

Generation algorithm

$$x_n = x_{n_1} \oplus v_c$$

$$u_n = x_n / 2^{32}$$

The value c is the right-most zero bit in $n - 1$; x_n is s -dimensional vector of 32-bit values. The s -dimensional vectors (calculated during engine initialization) $v_i, i = 1, 32$ are called direction numbers. The vector u_n is the generator output normalized to the unit hypercube $(0, 1)^s$.

class sobol

Syntax

```
namespace oneapi::mkl::rng {
class sobol {
public:
    static constexpr std::uint32_t default_dimensions_number = 1;

    sobol(sycl::queue queue, std::uint32_t dimensions = default_dimensions_number);

    sobol(sycl::queue queue, std::vector<std::uint32_t>& direction_numbers);

    sobol(const sobol& other);

    sobol(sobol&& other);

    sobol& operator=(const sobol& other);

    sobol& operator=(sobol&& other);

    ~sobol();
};
}
```

Class Members

Routine	Description
<code>sobol(sycl::queue queue, std::uint32_t dimensions = default_dimensions_number)</code>	Constructor with specified number of dimensions. The value should be 1..40.
<code>sobol(sycl::queue queue, std::vector<std::uint32_t>& direction_numbers)</code>	Constructor for extended use-case, when it's needed to use the number of dimensions greater than 40 or obtain another sequence.
<code>sobol(const sobol& other)</code>	Copy constructor
<code>sobol(sobol&& other)</code>	Move constructor
<code>sobol& operator=(const sobol& other)</code>	Copy assignment operator
<code>sobol& operator=(sobol&& other)</code>	Move assignment operator

Constructors

```
sobol::sobol(sycl::queue queue, std::uint32_t dimensions = default_dimensions_number)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

dimensions Number of dimensions. If $dimen < 1$ or $dimen > 40$, assume $dimen = 1$.

```
sobol::sobol(sycl::queue queue, std::vector<std::uint32_t>& direction_numbers)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

direction_numbers If you want to generate quasi-random vectors of greater dimension or obtain another sequence, you can register a set of your own `direction_numbers`. The number of dimensions corresponds to `direction_numbers.size() / 32`.

```
sobol::sobol(const sobol& other)
```

Input Parameters

other Valid `sobol` object. The queue and state of the other engine is copied and applied to the current engine.

```
sobol::sobol(sobol&& other)
```

Input Parameters

other Valid sobol object. The queue and state of the other engine is moved to the current engine.

```
sobol::sobol& operator=(const sobol& other)
```

Input Parameters

other Valid sobol object. The queue and state of the other engine is copied and applied to the current engine.

```
sobol::sobol& operator=(sobol&& other)
```

Input Parameters

other Valid sobol r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

niederreiter

The niederreiter generator is a 32-bit Gray code-based quasi-random number generator.

Description

According to results of Bratley, Fox and Niederreiter [*Bratley92*] Niederreiter sequences have the best known theoretical asymptotic properties. The default dimension of quasi-random vectors can vary from 1 to 318 inclusive. It is also allowed to register user-defined parameters (irreducible polynomials).

Generation algorithm

$$x_n = x_{n_1} \oplus v_c$$

$$u_n = x_n / 2^{32}$$

The value c is the right-most zero bit in $n - 1$; x_n is s-dimensional vector of 32-bit values. The s-dimensional vectors (calculated during engine initialization) $v_i, i = 1, 32$ are called direction numbers. The vector u_n is the generator output normalized to the unit hypercube $(0, 1)^s$.

class niederreiter**Syntax**

```

namespace oneapi::mkl::rng {
class niederreiter {
public:
    static constexpr std::uint32_t default_dimensions_number = 1;

    niederreiter(sycl::queue queue, std::uint32_t dimensions = default_dimensions_
↪number);

    niederreiter(sycl::queue queue, std::vector<std::uint32_t>& irred_polynomials);

    niederreiter(const niederreiter& other);

    niederreiter(niederreiter&& other);

    niederreiter& operator=(const niederreiter& other);

    niederreiter& operator=(niederreiter&& other);

    ~niederreiter();
};
}

```

Class Members

Routine	Description
<i>niederreiter(sycl::queue queue, std::uint32_t dimensions = default_dimensions_number)</i>	Constructor with specified number of dimensions. The value should be 1..318.
<i>niederreiter(sycl::queue queue, std::vector<std::uint32_t>& irred_polynomials)</i>	Constructor for extended use-case, when it's needed to use the number of dimensions greater than 318 or obtain another sequence.
<i>niederreiter(const niederreiter& other)</i>	Copy constructor
<i>niederreiter(niederreiter&& other)</i>	Move constructor
<i>niederreiter& operator=(const niederreiter& other)</i>	Copy assignment operator
<i>niederreiter& operator=(niederreiter&& other)</i>	Move assignment operator

Constructors

```
niederreiter::niederreiter(sycl::queue queue, std::uint32_t dimensions = default_
↳dimensions_number)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

dimensions Number of dimensions. If $dimen < 1$ or $dimen > 318$, assume $dimen = 1$.

```
niederreiter::niederreiter(sycl::queue queue, std::vector<std::uint32_t>& irred_
↳polynomials)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

irred_polynomials If you want to generate quasi-random vectors of greater dimension or obtain another sequence, you can register a set of your own irreducible polynomials. The number of dimensions corresponds to the length of the vector.

```
niederreiter::niederreiter(const niederreiter& other)
```

Input Parameters

other Valid `niederreiter` object. The queue and state of the other engine is copied and applied to the current engine.

```
niederreiter::niederreiter(niederreiter&& other)
```

Input Parameters

other Valid `niederreiter` object. The queue and state of the other engine is moved to the current engine.

```
niederreiter::niederreiter& operator=(const niederreiter& other)
```

Input Parameters

other Valid `niederreiter` object. The queue and state of the other engine is copied and applied to the current engine.

```
niederreiter::niederreiter& operator=(niederreiter&& other)
```

Input Parameters

other Valid `niederreiter` r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

nondeterministic

Non-deterministic random number generator.

Description

Implementation defined generator with non-deterministic source of randomness (for example, a hardware device).

class nondeterministic

Syntax

```

namespace oneapi::mkl::rng {
class nondeterministic {
public:
    nondeterministic(sycl::queue queue);

    nondeterministic(const nondeterministic& other);

    nondeterministic(nondeterministic&& other);

    nondeterministic& operator=(const nondeterministic& other);

    nondeterministic& operator=(nondeterministic&& other);

    ~nondeterministic();
};
}

```

Class Members

Routine	Description
<i>nondeterministic(sycl::queue queue)</i>	Constructor for the particular device
<i>nondeterministic(const nondeterministic& other)</i>	Copy constructor
<i>nondeterministic(nondeterministic&& other)</i>	Move constructor
<i>nondeterministic& operator=(const nondeterministic& other)</i>	Copy assignment operator
<i>nondeterministic& operator=(nondeterministic&& other)</i>	Move assignment operator

Constructors

```
nondeterministic::nondeterministic(sycl::queue queue)
```

Input Parameters

queue Valid `sycl::queue` object, calls of the `oneapi::mkl::rng::generate()` routine submits kernels in this queue to obtain random numbers from a given engine.

```
nondeterministic::nondeterministic(const nondeterministic& other)
```

Input Parameters

other Valid `nondeterministic` object. The queue and state of the other engine is copied and applied to the current engine.

```
nondeterministic::nondeterministic(nondeterministic&& other)
```

Input Parameters

other Valid `nondeterministic` object. The queue and state of the other engine is moved to the current engine.

```
nondeterministic::nondeterministic& operator=(const nondeterministic& other)
```

Input Parameters

other Valid `nondeterministic` object. The queue and state of the other engine is copied and applied to the current engine.

```
nondeterministic::nondeterministic& operator=(nondeterministic&& other)
```

Input Parameters

other Valid `nondeterministic` r-value object. The queue and state of the other engine is moved to the current engine.

Parent topic: *Engines (Basic Random Number Generators)*

Service Routines

Routine	Description
<i>leapfrog</i>	Proceed state of engine by the leapfrog method to generate a subsequence of the original sequence
<i>skip_ahead</i>	Proceed state of engine by the skip-ahead method to skip a given number of elements from the original sequence

Parent topic: *Random Number Generators*

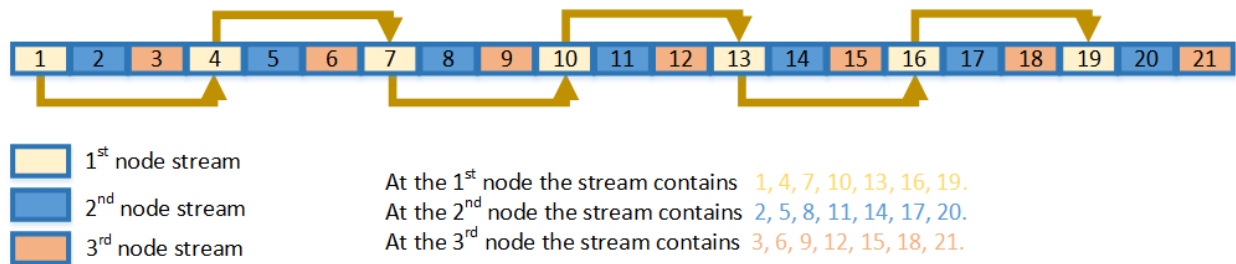

leapfrog

Proceed state of engine by the leapfrog method.

Description and Assumptions

`oneapi::mkl::rng::leapfrog` function generates random numbers in an engine with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the stride buffers without generating the original random sequence with subsequent manual distribution. see *Figure “Leapfrog Method”*.

Leapfrog Method

leapfrog

Syntax

```
namespace oneapi::mkl::rng {
template<typename EngineType>
void leapfrog(EngineType& engine, std::uint64_t idx, std::uint64_t stride);
}
```

Template Parameters

EngineType Type of engine. Note: may not be supported by all available engine classes.

Input Parameters

engine Engine which state would be skipped.

idx Index of the computational node.

stride Largest number of computational nodes, or stride.

Example

```
// Creating 3 identical engines
oneapi::mkl::rng::mcg31m1 engine_1(queue, seed);

oneapi::mkl::rng::mcg31m1 engine_2(engine_1);
oneapi::mkl::rng::mcg31m1 engine_3(engine_1);

// Leapfrogging the states of engines
oneapi::mkl::rng::leapfrog(engine_1, 0, 3);
oneapi::mkl::rng::leapfrog(engine_2, 1, 3);
oneapi::mkl::rng::leapfrog(engine_3, 2, 3);
// Generating random numbers
```

Parent topic: *Service Routines*

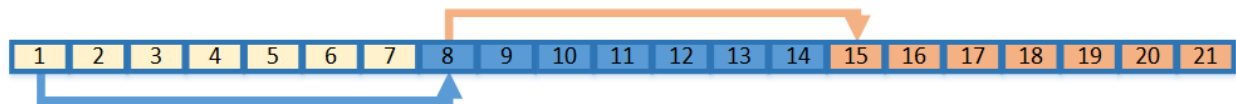

skip Ahead

Proceed state of engine by the skip-ahead method.

Description and Assumptions

oneapi::mkl::rng::skip Ahead function changes the current state of the engine so that with the further call of the generator the output subsequence begins with the specified offset see *Figure “Block-Splitting Method”*.

Block-Splitting Method

- 1st node stream
- 2nd node stream
- 3rd node stream

At the 1st node the stream contains 1, 2, 3, 4, 5, 6, 7.
 At the 2nd node the stream contains 8, 9, 10, 11, 12, 13, 14.
 At the 3rd node the stream contains 15, 16, 17, 18, 19, 20, 21.

skip Ahead

Syntax

```
namespace oneapi::mkl::rng {
template<typename EngineType>
void skip Ahead(EngineType& engine, std::uint64_t num_to_skip);
}
```

Template Parameters

EngineType Type of engine. Note: may not be supported by all available engine classes.

Input Parameters

engine Engine which state would be skipped.

num_to_skip Number of elements to skip in the engine's sequence.

Example

```
// Creating 3 identical engines
oneapi::mkl::rng::mcg31m1 engine_1(queue, seed);
oneapi::mkl::rng::mcg31m1 engine_2(engine_1);
oneapi::mkl::rng::mcg31m1 engine_3(engine_2);

// Skipping ahead by 7 elements the 2nd engine
oneapi::mkl::rng::skip_ahead(engine_2, 7);

// Skipping ahead by 14 elements the 3rd engine
oneapi::mkl::rng::skip_ahead(engine_3, 14);
```

skip_ahead (Interface with a partitioned number of skipped elements)

Syntax

```
namespace oneapi::mkl::rng {
template<typename EngineType>
void oneapi::mkl::rng::skip_ahead(EngineType& engine, std::initializer_list<std::uint64_
↳t> num_to_skip);
}
```

Template Parameters

EngineType Type of engine. Note: may not be supported by all available engine classes.

Input Parameters

engine Engine which state would be skipped.

num_to_skip Partitioned number of elements to skip in the engine's sequence. The total number of skipped elements would be: $num_to_skip[0] + num_to_skip[1] \cdot 2^{64} + \dots + num_to_skip[n-1] \cdot 2^{64(n-1)}$, where n is a number of elements in num_to_skip list.

Example with Partitioned Numer of Elements

```
// Creating the first engine
oneapi::mkl::rng::mrg32k3a engine_1(queue, seed);

// To skip 2^64 elements in the random stream number of skipped elements should be
//represented as num_to_skip = 2^64 = 0 + 1 * 2^64
std::initializer_list<std::uint64_t> num_to_skip = {0, 1};

// Creating the 2nd engine based on 1st. Skipping by 2^64
oneapi::mkl::rng::mrg32k3a engine_2(engine_1);
oneapi::mkl::rng::skip_ahead(engine_2, num_to_skip);
```

Distributions

oneMKL RNG routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence and the explanation of input and output parameters. [Table Continuous Distribution Generators](#) and [Table Discrete Distribution Generators](#) list the random number generator routines with data types and output distributions, and sets correspondence between data types of the generator routines and the basic random number generators.

Table Continuous Distribution Generators

Routine	Description
<i>uniform (continuous)</i>	Uniform continuous distribution on the interval [a, b)
<i>gaussian</i>	Normal (Gaussian) distribution
<i>exponential</i>	Exponential distribution
<i>laplace</i>	Laplace distribution (double exponential distribution)
<i>weibull</i>	Weibull distribution
<i>cauchy</i>	Cauchy distribution
<i>rayleigh</i>	Rayleigh distribution
<i>lognormal</i>	Lognormal distribution
<i>gumbel</i>	Gumbel (extreme value) distribution
<i>gamma</i>	Gamma distribution
<i>beta</i>	Beta distribution
<i>chi_square</i>	Chi-Square distribution
<i>gaussian_mv</i>	Normal Multivariate (Gaussian Multivariate) distribution

Table Discrete Distribution Generators

Type of Distribution	Description
<i>uniform (discrete)</i>	Uniform discrete distribution on the interval [a, b)
<i>uniform_bits</i>	Uniformly distributed bits in 32/64-bit chunks
<i>bits</i>	Bits of underlying BRNG integer recurrence
<i>bernoulli</i>	Bernoulli distribution
<i>geometric</i>	Geometric distribution
<i>binomial</i>	Binomial distribution
<i>hypergeometric</i>	Hypergeometric distribution
<i>poisson</i>	Poisson distribution
<i>poisson_v</i>	Poisson distribution with varying mean
<i>negative_binomial</i>	Negative binomial distribution, or Pascal distribution
<i>multinomial</i>	Multinomial distribution

Modes of random number generation

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within the definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval [a,b] belong to this interval irrespective of what a and b values may be. Fast mode provides high performance generation and also guarantees that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying the relevant value of the method parameter in generator routines. The list of distributions that support accurate mode of generation is given in the table below.

Table Distribution Generators with Accurate Method

Distribution	Method
<i>uniform (continuous)</i>	<code>oneapi::mkl::rng::uniform_method::accurate</code>
<i>exponential</i>	<code>oneapi::mkl::rng::exponential_method::icdf_accurate</code>
<i>weibull</i>	<code>oneapi::mkl::rng::weibull_method::icdf_accurate</code>
<i>rayleigh</i>	<code>oneapi::mkl::rng::rayleigh_method::icdf_accurate</code>
<i>lognormal</i>	<code>oneapi::mkl::rng::lognormal_method::box_muller2_accurate,</code> <code>oneapi::mkl::rng::lognormal_method::icdf_accurate</code>
<i>gamma</i>	<code>oneapi::mkl::rng::gamma_method::marsaglia_accurate</code>
<i>beta</i>	<code>oneapi::mkl::rng::beta_method::cja_accurate</code>

Parent topic: *Random Number Generators*

Distributions Template Parameter Method

Method	Dis-tributions	Math Description
uniform_method: uniform_method::accurate uniform_method: uniform(i)	uniform	Standard method. uniform_method::standard_accurate supported for uniform(s, d) only.
gaussian_method: gaussian(i)	gaussian	Generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula: $x = \sqrt{-2\ln u_1} \sin(2\pi u_2)$
gaussian_method: gaussian(i)	gaussian	Generates 2 normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas: $x_1 = \sqrt{-2\ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2\ln u_1} \cos 2\pi u_2$
gaussian_method: gaussian(i)	gaussian	Inverse cumulative distribution function (ICDF) method.
exponential_method: exponential_method: exponential_method: exponential_method::icdf_accurate	exponential	Inverse cumulative distribution function (ICDF) method.
weibull_method: weibull_method: weibull_method: weibull_method::icdf_accurate	weibull	Inverse cumulative distribution function (ICDF) method.
cauchy_method: cauchy(i)	cauchy	Inverse cumulative distribution function (ICDF) method.
rayleigh_method: rayleigh(i)	rayleigh	Inverse cumulative distribution function (ICDF) method.
bernoulli_method: bernoulli(i)	bernoulli	Inverse cumulative distribution function (ICDF) method.
geometric_method: geometric(i)	geometric	Inverse cumulative distribution function (ICDF) method.
gumbel_method: gumbel(i)	gumbel	Inverse cumulative distribution function (ICDF) method.
lognormal_method: lognormal(i)	lognormal	Inverse cumulative distribution function (ICDF) method.
lognormal_method: lognormal(i)	lognormal	Inverse cumulative distribution function (ICDF) method.
lognormal_method: lognormal(i)	lognormal	Generates 2 normally distributed random numbers x_1 and x_2 by box_muller2 method are lognormal_method::box_muller2_lognormal distribution.
gamma_method: gamma(i)	gamma	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled gamma distributed number; for $0.6 \leq \alpha < 1$, a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.
beta_method: beta(i)	beta	Cheng-Jonhnk-Atkinson method. For $\min(p, q) > 1$, Cheng method is used; for $\min(p, q) < 1$, Johnk method is used, if $q + K * p^2 + C \leq 0$ ($K = 0.852...$, $C = -0.956...$) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$, method of Johnk is used; for $\min(p, q) < 1$, $\max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for Cheng, Johnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.
chi_square_method: chi_square(i)	chi_square	Gamma based (offset): If $\nu \geq 17$ or ν is odd and $5 \leq \nu \leq 15$, a chi-square distribution is reduced to a Gamma distribution with these parameters: Shape $\alpha = \nu/2$ Offset $a = 0$ Scale factor $\beta = 2$ The random numbers of the Gamma distribution are generated.
binomial_method: binomial(i)	binomial	Acceptance/rejection method for $ntrial * \min(p, 1 - p) \geq 30$ with decomposition into four regions: two parallelograms, triangle, left exponential tail, right exponential tail.
poisson_method: poisson(i)	poisson	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into four regions: two parallelograms, triangle, left exponential tail, right exponential tail.
poisson_method: poisson(i)	poisson	Gamma based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.
poisson_v_method: poisson_v(i)	poisson	Gamma based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.
hypergeometric_method: hypergeometric(i)	hypergeometric	Acceptance/rejection method for large mode of distribution with decomposition into three regions: rectangular, left exponential tail, right exponential tail.
1.2.2 oneAPI multinomial_method: multinomial(i)	multinomial	Rejection method for: $\frac{(a-1)(1-p)}{p} \geq 100$ with decomposition into five regions: rectangular, 2 trapezoid, left exponential tail, right exponential tail.
		with parameters m, k , and a probability vector p . Random numbers of the multinomial distribution are generated by Poisson Approximation method.

Parent topic: *Distributions*

uniform (continuous)

Class is used for generation of uniformly distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers uniformly distributed over the interval $[a, b)$, where a, b are the left and right bounds of the interval, respectively, and $a, b \in R; a < b$

The probability distribution is given by:

$$f_{a,b}(x) = \begin{cases} \frac{1}{b-a}, & x \in [a, b) \\ 0, & x \notin [a, b) \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{x-a}{b-a}, & a \leq x < b \\ 1, & x \geq b \end{cases}$$

class uniform

Syntax

```
namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = uniform_method::by_default>
class uniform {
public:
    using method_type = Method;
    using result_type = RealType;
    uniform();
    explicit uniform(RealType a, RealType b);
    RealType a() const;
    RealType b() const;
};
}
```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = oneapi::mkl::rng::uniform_method::by_default Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::uniform_method::by_default

- `oneapi::mkl::rng::uniform_method::standard`
- `oneapi::mkl::rng::uniform_method::accurate`

See description of the methods in *Distributions methods template parameter*

Class Members

Routine	Description
<code>uniform()</code>	Default constructor
<code>explicit uniform(RealType a, RealType b)</code>	Constructor with parameters
<code>RealType a() const</code>	Method to obtain left bound <i>a</i>
<code>RealType b() const</code>	Method to obtain right bound <i>b</i>

Member types

```
uniform::method_type = Method
```

Description

The type which defines transformation method for generation.

```
uniform::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
uniform::uniform()
```

Description

Default constructor for distribution, parameters set as $a = 0.0$, $b = 1.0$.

```
explicit uniform::uniform(RealType a, RealType b)
```

Description

Constructor with parameters. a is a left bound, b is a right bound, assume $a < b$.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $a \geq b$

Characteristics

```
RealType uniform::a() const
```

Return Value

Returns the distribution parameter a - left bound.

```
RealType uniform::b() const
```

Return Value

Returns the distribution parameter b - right bound.

Parent topic: *Distributions*

gaussian

Class is used for generation of normally distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers normally distributed with mean (*mean*, a) and standard deviation (*stddev*, σ), where $a, \sigma \in R; \sigma > 0$.

The probability distribution is given by:

$$f_{a,\sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-a)^2}{2*\sigma^2}\right), x \in R.$$

The cumulative distribution function is as follows:

$$F_{a,\sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y-a)^2}{2*\sigma^2}\right) dy, x \in R.$$

class gaussian

Syntax

```

namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = gaussian_method::by_default>
class gaussian {
public:
    using method_type = Method;
    using result_type = RealType;
    gaussian();
    explicit gaussian(RealType mean, RealType stddev);
    RealType mean() const;
    RealType stddev() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = oneapi::mkl::rng::gaussian_method::by_default Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::gaussian_method::by_default
- oneapi::mkl::rng::gaussian_method::box_muller
- oneapi::mkl::rng::gaussian_method::box_muller2
- oneapi::mkl::rng::gaussian_method::icdf

See description of the methods in *Distributions methods template parameter*

Class Members

Routine	Description
<i>gaussian()</i>	Default constructor
<i>explicit gaussian(RealType mean, RealType stddev)</i>	Constructor with parameters
<i>RealType mean() const</i>	Method to obtain mean value
<i>RealType stddev() const</i>	Method to obtain standard deviation value

Member types

```
gaussian::method_type = Method
```

Description

The type which defines transformation method for generation.

```
gaussian::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
gaussian::gaussian()
```

Description

Default constructor for distribution, parameters set as *mean* = 0.0, *stddev* = 1.0.

```
explicit gaussian::gaussian(RealType mean, RealType stddev)
```

Description

Constructor with parameters. *mean* is a mean value, *stddev* is a standard deviation value.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $stddev \leq static_cast<RealType>(0.0)$

Characteristics

```
RealType gaussian::mean() const
```

Return Value

Returns the distribution parameter *mean* - mean value.

```
RealType gaussian::stddev() const
```

Return Value

Returns the distribution parameter *stddev* - standard deviation value.

Parent topic: *Distributions*

exponential

Class is used for generation of exponentially distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers exponentially distributed with displacement a and scalefactor β , where $a, \beta \in R; \beta > 0$.

The probability distribution is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp(-\frac{x-a}{\beta}), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp(-\frac{x-a}{\beta}), & x \geq a \\ 0, & x < a \end{cases}$$

class exponential

Syntax

```

namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = exponential_method::by_default>
class exponential {
public:
    using method_type = Method;
    using result_type = RealType;
    exponential();
    explicit exponential(RealType a, RealType beta);
    RealType a() const;
    RealType beta() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = oneapi::mkl::rng::exponential_method::by_default Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::exponential_method::by_default`
- `oneapi::mkl::rng::exponential_method::icdf`
- `oneapi::mkl::rng::exponential_method::icdf_accurate`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<code>exponential()</code>	Default constructor
<code>explicit exponential(RealType a, RealType beta)</code>	Constructor with parameters
<code>RealType a() const</code>	Method to obtain displacement value
<code>RealType beta() const</code>	Method to obtain scalefactor

Member types

```
exponential::method_type = Method
```

Description

The type which defines transformation method for generation.

```
exponential::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
exponential::exponential()
```

Description

Default constructor for distribution, parameters set as $a = 0.0$, $beta = 1.0$.

```
explicit exponential::exponential(RealType a, RealType beta)
```

Description

Constructor with parameters. a is a displacement, $beta$ is a scalefactor.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $beta \leq \text{static_cast}\langle\text{RealType}\rangle(0.0)$

Characteristics

```
RealType exponential::a() const
```

Return Value

Returns the distribution parameter a - displacement.

```
RealType exponential::beta() const
```

Return Value

Returns the distribution parameter $beta$ - scalefactor value.

Parent topic: *Distributions*

laplace

Class is used for generation of Laplace distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers Laplace distributed with mean value (or average) a , and scalefactor (b, β), where $a, \beta \in R; \beta > 0$. The scalefactor value determines the standard deviation as $\sigma = \beta\sqrt{2}$.

The probability distribution is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2}\beta} \exp\left(-\frac{|x-a|}{\beta}\right), x \in R.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}$$

class laplace

Syntax

```

template<typename RealType = float, typename Method = laplace_method::by_default>
class laplace {
public:
    using method_type = Method;
    using result_type = RealType;
    laplace();
    explicit laplace(RealType a, RealType b);
    RealType a() const;
    RealType b() const;
};

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = **oneapi::mkl::rng::laplace_method::by_default** Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::laplace_method::by_default
- oneapi::mkl::rng::laplace_method::icdf

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>laplace()</i>	Default constructor
<i>explicit laplace(RealType a, RealType b)</i>	Constructor with parameters
<i>RealType a() const</i>	Method to obtain mean value
<i>RealType b() const</i>	Method to obtain scalefactor value

Member types

```
laplace::method_type = Method
```

Description

The type which defines transformation method for generation.

```
laplace::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
laplace::laplace()
```

Description

Default constructor for distribution, parameters set as $a = 0.0$, and $beta = 1.0$.

```
explicit laplace::laplace(RealType a, RealType b)
```

Description

Constructor with parameters. a is a mean value, $beta$ is a scalefactor value.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $b \leq \text{static_cast}<\text{RealType}>(0.0)$

Characteristics

```
RealType laplace::a() const
```

Return Value

Returns the distribution parameter a - mean value.

```
RealType laplace::b() const
```

Return Value

Returns the distribution parameter b - scalefactor value.

Parent topic: *Distributions*

weibull

Class is used for generation of Weibull distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers Weibull distributed with displacement a , scalefactor β , and shape α , where $a, \beta, \alpha \in R; \alpha > 0; \beta > 0$.

The probability distribution is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\frac{x-a}{\beta}^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{x-a}{\beta}^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

class weibull

Syntax

```

namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = weibull_method::by_default>
class weibull {
public:
    using method_type = Method;
    using result_type = RealType;
    weibull();
    explicit weibull(RealType alpha, RealType a, RealType b);
    RealType alpha() const;
    RealType a() const;
    RealType beta() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = oneapi::mkl::rng::weibull_method::by_default Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::weibull_method::by_default
- oneapi::mkl::rng::weibull_method::icdf
- oneapi::mkl::rng::weibull_method::icdf_accurate

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>weibull()</i>	Default constructor
<i>explicit weibull(RealType alpha, RealType a, RealType beta)</i>	Constructor with parameters
<i>RealType alpha() const</i>	Method to obtain shape value
<i>RealType a() const</i>	Method to obtain displacement value
<i>RealType beta() const</i>	Method to obtain scalefactor value

Member types

```
weibull::method_type = Method
```

Description

The type which defines transformation method for generation.

```
weibull::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
weibull::weibull()
```

Description

Default constructor for distribution, parameters set as $\alpha = 1.0$, $a = 0.0$, and $b = 1.0$.

```
explicit weibull::weibull(RealType alpha, RealType a, RealType beta)
```

Description

Constructor with parameters. α is a shape value, a is a displacement value, b is a scalefactor value.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $\alpha \leq \text{static_cast}\langle\text{RealType}\rangle(0.0)$, or $beta \leq \text{static_cast}\langle\text{RealType}\rangle(0.0)$

Characteristics

```
RealType weibull::alpha() const
```

Return Value

Returns the distribution parameter α - shape value.

```
RealType weibull::a() const
```

Return Value

Returns the distribution parameter a - displacement value.

```
RealType weibull::beta() const
```

Return Value

Returns the distribution parameter $beta$ - scalefactor value.

Parent topic: *Distributions*

cauchy

Class is used for generation of Cauchy distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers Cauchy distributed with displacement a , and scale parameter (b, β) , where $a, \beta \in R; \beta > 0$.

The probability distribution is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta(1 + (\frac{x-a}{\beta})^2)}, x \in R.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \frac{1}{2} + \frac{1}{\pi} \arctan\left(\frac{x-a}{\beta}\right), x \in R.$$

class cauchy

Syntax

```

namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = cauchy_method::by_default>
class cauchy {
public:
    using method_type = Method;
    using result_type = RealType;
    cauchy();
    explicit cauchy(RealType a, RealType b);
    RealType a() const;
    RealType b() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = `oneapi::mkl::rng::cauchy_method::by_default` Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::cauchy_method::by_default`
- `oneapi::mkl::rng::cauchy_method::icdf`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>cauchy()</i>	Default constructor
<i>explicit cauchy(RealType a, RealType b)</i>	Constructor with parameters
<i>RealType a() const</i>	Method to obtain displacement value
<i>RealType b() const</i>	Method to obtain scalefactor value

Member types

```
cauchy::method_type = Method
```

Description

The type which defines transformation method for generation.

```
cauchy::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
cauchy::cauchy()
```

Description

Default constructor for distribution, parameters set as $a = 0.0$, and $b = 1.0$.

```
explicit cauchy::cauchy(RealType a, RealType b)
```

Description

Constructor with parameters. a is a displacement value, b is a scalefactor value.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $b \leq \text{static_cast}<\text{RealType}>(0.0)$

Characteristics

```
RealType cauchy::a() const
```

Return Value

Returns the distribution parameter a - displacement value.

```
RealType cauchy::b() const
```

Return Value

Returns the distribution parameter b - scalefactor value.

Parent topic: *Distributions*

rayleigh

Class is used for generation of Rayleigh distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers Rayleigh distributed with displacement a , and scalefactor (b, β) , where $a, \beta \in R; \beta > 0$.

The Rayleigh distribution is a special case of the *weibull* distribution, where the shape parameter $alpha = 2$.

The probability distribution is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}$$

class rayleigh

Syntax

```
namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = rayleigh_method::by_default>
class rayleigh {
public:
    using method_type = Method;
    using result_type = RealType;
    rayleigh();
    explicit rayleigh(RealType a, RealType b);
```

(continues on next page)

(continued from previous page)

```

RealType a() const;
RealType b() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = **oneapi::mkl::rng::rayleigh_method::by_default** Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::rayleigh_method::by_default
- oneapi::mkl::rng::rayleigh_method::icdf
- oneapi::mkl::rng::rayleigh_method::icdf_accurate

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>rayleigh()</i>	Default constructor
<i>explicit rayleigh(RealType a, RealType b)</i>	Constructor with parameters
<i>RealType a() const</i>	Method to obtain displacement value
<i>RealType b() const</i>	Method to obtain scalefactor value

Member types

```
rayleigh::method_type = Method
```

Description

The type which defines transformation method for generation.

```
rayleigh::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
rayleigh::rayleigh()
```

Description

Default constructor for distribution, parameters set as $a = 0.0$, and $b = 1.0$.

```
explicit rayleigh::rayleigh(RealType a, RealType b)
```

Description

Constructor with parameters. a is a displacement value, b is a scalefactor value.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $b \leq \text{static_cast}<\text{RealType}>(0.0)$

Characteristics

```
RealType rayleigh::a() const
```

Return Value

Returns the distribution parameter a - displacement value.

```
RealType rayleigh::b() const
```

Return Value

Returns the distribution parameter b - scalefactor value.

Parent topic: *Distributions*

lognormal

Class is used for generation of lognormally distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers lognormally distributed with mean (m, a) and standard deviation (s, σ) of subject normal distribution, displacement ($displ, b$), and scalefactor ($scale, \beta$), where $a, \sigma, b, \beta \in R; \sigma > 0; \beta > 0$.

The probability distribution is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x-b)/\beta)-a]^2}{2*\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi\left(\frac{\ln((x-b)/\beta)-a}{\sigma}\right), & x > b \\ 0, & x \leq b \end{cases}$$

class lognormal

Syntax

```
namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = lognormal_method::by_default>
class lognormal {
public:
    using method_type = Method;
    using result_type = RealType;
    lognormal();
    explicit lognormal(RealType m, RealType s, RealType displ = static_cast<RealType>(0.
↪0), RealType scale = static_cast<RealType>(1.0));
    RealType m() const;
    RealType s() const;
    RealType displ() const;
    RealType scale() const;
};
}
```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = `oneapi::mkl::rng::lognormal_method::by_default` Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::lognormal_method::by_default`

- `oneapi::mkl::rng::lognormal_method::box_muller2`
- `oneapi::mkl::rng::lognormal_method::icdf`
- `oneapi::mkl::rng::lognormal_method::box_muller2_accurate`
- `oneapi::mkl::rng::lognormal_method::icdf_accurate`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<code>lognormal()</code>	Default constructor
<code>explicit lognormal(RealType m, RealType s, RealType displ = static_cast<RealType>(0.0), RealType scale = static_cast<RealType>(1.0))</code>	Constructor with parameters
<code>RealType m() const</code>	Method to obtain mean value
<code>RealType s() const</code>	Method to obtain standard deviation value
<code>RealType displ() const</code>	Method to obtain displacement value
<code>RealType scale() const</code>	Method to obtain scale-factor value

Member types

```
lognormal::method_type = Method
```

Description

The type which defines transformation method for generation.

```
lognormal::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
lognormal::lognormal()
```

Description

Default constructor for distribution, parameters set as $m = 0.0$, $s = 1.0$, $displ = 0.0$, $scale = 1.0$.

```
explicit lognormal::lognormal(RealType m, RealType s, RealType displ = static_cast
↳<RealType>(0.0), RealType scale = static_cast<RealType>(1.0))
```

Description

Constructor with parameters. m is a mean value, s is a standard deviation value, $displ$ is a displacement value, $scale$ is a scalefactor value.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $s \leq \text{static_cast}<\text{RealType}>(0.0)$, or $scale \leq \text{static_cast}<\text{RealType}>(0.0)$

Characteristics

```
RealType lognormal::m() const
```

Return Value

Returns the distribution parameter m - mean value.

```
RealType lognormal::s() const
```

Return Value

Returns the distribution parameter s - standard deviation value.

```
RealType lognormal::displ() const
```

Return Value

Returns the distribution parameter $displ$ - displacement value.

```
RealType lognormal::scale() const
```

Return Value

Returns the distribution parameter *scale* - scalefactor value.

Parent topic: *Distributions*

gumbel

Class is used for generation of Gumbel distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers Gumbel distributed with displacement a , and scalefactor (b, β) , where $a, \beta \in R; \beta > 0$.

The probability distribution is given by:

$$f_{a,\beta}(x) = \frac{1}{\beta} \exp\left(-\frac{x-a}{\beta}\right) \exp\left(-\exp\left(\frac{x-a}{\beta}\right)\right), x \in R.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = 1 - \exp\left(-\exp\left(\frac{x-a}{\beta}\right)\right), x \in R.$$

class gumbel

Syntax

```
namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = gumbel_method::by_default>
class gumbel {
public:
    using method_type = Method;
    using result_type = RealType;
    gumbel();
    explicit gumbel(RealType a, RealType b);
    RealType a() const;
    RealType b() const;
};
}
```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = oneapi::mkl::rng::gumbel_method::by_default Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::gumbel_method::by_default`
- `oneapi::mkl::rng::gumbel_method::icdf`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<code>gumbel()</code>	Default constructor
<code>explicit gumbel(RealType a, RealType b)</code>	Constructor with parameters
<code>RealType a() const</code>	Method to obtain displacement value
<code>RealType b() const</code>	Method to obtain scalefactor value

Member types

```
gumbel::method_type = Method
```

Description

The type which defines transformation method for generation.

```
gumbel::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
gumbel::gumbel()
```

Description

Default constructor for distribution, parameters set as $a = 0.0$, and $beta = 1.0$.

```
explicit gumbel::gumbel(RealType a, RealType b)
```

Description

Constructor with parameters. a is a displacement value, $beta$ is a scalefactor value.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $b \leq \text{static_cast}\langle\text{RealType}\rangle(0.0)$

Characteristics

```
RealType gumbel::a() const
```

Return Value

Returns the distribution parameter a - displacement value.

```
RealType gumbel::b() const
```

Return Value

Returns the distribution parameter b - scalefactor value.

Parent topic: *Distributions*

gamma

Class is used for generation of gamma distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers gamma distributed with shape α , displacement a , and scale parameter β , where $a, \alpha, \beta \in R; \alpha > 0; \beta > 0$.

The probability distribution is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x-a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y-a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}$$

class gamma

Syntax

```

namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = gamma_method::by_default>
class gamma {
public:
    using method_type = Method;
    using result_type = RealType;
    gamma();
    explicit gamma(RealType alpha, RealType a, RealType beta);
    RealType alpha() const;
    RealType a() const;
    RealType beta() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = oneapi::mkl::rng::gamma_method::by_default Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::gamma_method::by_default
- oneapi::mkl::rng::gamma_method::marsaglia
- oneapi::mkl::rng::gamma_method::marsaglia_accurate

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>gamma()</i>	Default constructor
<i>explicit gamma(RealType alpha, RealType a, RealType beta)</i>	Constructor with parameters
<i>RealType alpha() const</i>	Method to obtain shape value
<i>RealType a() const</i>	Method to obtain displacement value
<i>RealType beta() const</i>	Method to obtain scale value

Member types

```
gamma::method_type = Method
```

Description

The type which defines transformation method for generation.

```
gamma::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
gamma::gamma()
```

Description

Default constructor for distribution, parameters set as $\alpha = 1.0$, $a = 0.0$, and $\beta = 1.0$.

```
explicit gamma::gamma(RealType alpha, RealType a, RealType beta)
```

Description

Constructor with parameters. α is a shape value, a is a displacement value, β is a scale parameter.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $\alpha \leq \text{static_cast}\langle\text{RealType}\rangle(0.0)$, or $\beta \leq \text{static_cast}\langle\text{RealType}\rangle(0.0)$

Characteristics

```
RealType gamma::alpha() const
```

Return Value

Returns the distribution parameter *alpha* - shape value.

```
RealType gamma::a() const
```

Return Value

Returns the distribution parameter *a* - displacement value.

```
RealType gamma::beta() const
```

Return Value

Returns the distribution parameter *beta* - scale parameter.

Parent topic: *Distributions*

beta

Class is used for generation of beta distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers beta distributed with shape parameters *p* and *q*, displacement *α* and scale parameter (*b*, *β*), where $p, q, \alpha, \beta \in R; p > 0; q > 0; \beta > 0$.

The probability distribution is given by:

$$f_{p,q,\alpha,\beta}(x) = \begin{cases} \frac{1}{B(p,q)*\beta^{p+q-1}}(x-\alpha)^{p-1} * (\beta+\alpha-x)^{q-1}, & \alpha \leq x < \alpha + \beta \\ 0, & x < \alpha, x \geq \alpha + \beta \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < \alpha \\ \int_{\alpha}^x \frac{1}{B(p,q)*\beta^{p+q-1}}(y-\alpha)^{p-1} * (\beta+\alpha-y)^{q-1} dy, & \alpha \leq x < \alpha + \beta, x \in R \\ 1, & x \geq \alpha + \beta \end{cases}$$

Where $B(p, 1)$ is the complete beta function.

class beta

Syntax

```
namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = beta_method::by_default>
class beta {
public:
    using method_type = Method;
    using result_type = RealType;
```

(continues on next page)

(continued from previous page)

```

beta();
explicit beta(RealType p, RealType q, RealType a, RealType b);
RealType p() const;
RealType q() const;
RealType a() const;
RealType b() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = oneapi::mkl::rng::beta_method::by_default Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::beta_method::by_default
- oneapi::mkl::rng::beta_method::cja
- oneapi::mkl::rng::beta_method::cja_accurate

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>beta()</i>	Default constructor
<i>explicit beta(RealType p, RealType q, RealType a, RealType b)</i>	Constructor with parameters
<i>RealType p() const</i>	Method to obtain shape p
<i>RealType q() const</i>	Method to obtain shape q
<i>RealType a() const</i>	Method to obtain displacement α
<i>RealType b() const</i>	Method to obtain scalefactor β

Member types

```
beta::method_type = Method
```

Description

The type which defines transformation method for generation.

```
beta::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
beta::beta()
```

Description

Default constructor for distribution, parameters set as $p = 1.0$, $q = 0.0$, $\alpha = 1.0$, $\beta = 1.0$.

```
explicit beta::beta(RealType p, RealType q, RealType a, RealType b)
```

Description

Constructor with parameters. p and q are shapes, α is a displacement, β is a scalefactor.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $p \leq 0.0f$, or $q \leq 0.0f$, or $\beta \leq 0.0f$

Characteristics

```
RealType beta::p() const
```

Return Value

Returns the distribution parameter p - shape.

```
RealType beta::q() const
```

Return Value

Returns the distribution parameter q - shape.

```
RealType beta::a() const
```

Return Value

Returns the distribution parameter α - displacement.

```
RealType beta::b() const
```

Return Value

Returns the distribution parameter β - scalefactor.

Parent topic: *Distributions*

chi_square

Class is used for generation of chi-square distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers chi-square distributed with n degrees of freedom, $n \in \mathbb{N}; n > 0$.

The probability distribution is given by:

$$f_n(x) = \begin{cases} \frac{x^{\frac{n-2}{2}} e^{-\frac{x}{2}}}{2^{n/2} \Gamma(n/2)}, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

The cumulative distribution function is as follows:

$$F_n(x) = \begin{cases} \int_0^x \frac{y^{\frac{n-2}{2}} e^{-\frac{y}{2}}}{2^{n/2} \Gamma(n/2)} dy, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

class chi_square

Syntax

```
namespace oneapi::mkl::rng {
template<typename RealType = float, typename Method = chi_square_method::by_default>
class chi_square {
public:
    using method_type = Method;
    using result_type = RealType;
    chi_square();
    explicit chi_square(std::int32_t n);
```

(continues on next page)

(continued from previous page)

```

std::int32_t n() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

typename Method = oneapi::mkl::rng::chi_square_method::by_default Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::chi_square_method::by_default
- oneapi::mkl::rng::chi_square_method::gamma_based

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>chi_square()</i>	Default constructor
<i>explicit chi_square(std::int32_t n)</i>	Constructor with parameters
<i>std::int32_t n() const</i>	Method to obtain number of degrees of freedom <i>n</i>

Member types

```
chi_square::method_type = Method
```

Description

The type which defines transformation method for generation.

```
chi_square::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
chi_square::chi_square()
```

Description

Default constructor for distribution, parameters set as $n = 5$.

```
explicit chi_square::chi_square(std::int32_t n)
```

Description

Constructor with parameters. n is the number of degrees of freedom.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $n < 1$

Characteristics

```
std::int32_t chi_square::n() const
```

Return Value

Returns the distribution parameter n - number of degrees of freedom.

Parent topic: *Distributions*

gaussian_mv

Class is used for generation of multivariate normally distributed real types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide n random numbers d -variate normally distributed, with mean a and variance-covariance matrix C , where $a \in R^d$; C is $d \times d$ symmetric positive matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp(-1/2(x - a)^T C^{-1}(x - a)).$$

class gaussian_mv

Syntax

```

namespace oneapi::mkl::rng {
template<typename RealType = std::int32_t, layout Layout = layout::packed, typename_
↳Method = gaussian_mv_method::by_default>
class gaussian_mv {
public:
    using method_type = Method;
    using result_type = RealType;
    explicit gaussian_mv(std::uint32_t dimen, std::vector<RealType> mean, std::vector
↳<RealType> matrix);
    std::int32_t dimen() const;
    std::vector<RealType> mean() const;
    std::vector<RealType> matrix() const;
};
}

```

Template parameters

typename RealType

Type of the produced values. Supported types:

- float
- double

Template parameters

oneapi::mkl::rng::layout Layout

Matrix layout:

- oneapi::mkl::rng::layout::full
- oneapi::mkl::rng::layout::packed
- oneapi::mkl::rng::layout::diagonal

typename Method = oneapi::mkl::rng::gaussian_mv_method::by_default Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::gaussian_mv_method::by_default
- oneapi::mkl::rng::gaussian_mv_method::box_muller
- oneapi::mkl::rng::gaussian_mv_method::box_muller2
- oneapi::mkl::rng::gaussian_mv_method::icdf

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<code>explicit gaussian_mv(std::uint32_t dimen, std::vector<RealType> mean, std::vector<RealType> matrix)</code>	Constructor with parameters
<code>std::int32_t dimen() const</code>	Method to obtain number of dimensions in output random vectors
<code>std::vector<double> mean() const</code>	Method to obtain mean vector a of dimension d .
<code>std::vector<double> matrix() const</code>	Method to obtain variance-covariance matrix C

Member types

```
gaussian_mv::method_type = Method
```

Description

The type which defines transformation method for generation.

```
gaussian_mv::result_type = RealType
```

Description

The type which defines type of generated random numbers.

Constructors

```
explicit gaussian_mv::gaussian_mv(std::uint32_t dimen, std::vector<RealType> mean, ↵
↵std::vector<RealType> matrix)
```

Description

Constructor with parameters. *dimen* is the number of dimensions, *mean* is a mean vector, *matrix* is a variance-covariance matrix.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $mean.size() \leq 0$, or $matrix.size() \leq 0$

Characteristics

```
std::int32_t gaussian_mv::dimen() const
```

Return Value

Returns the distribution parameter *dimen*.

```
std::vector<double> gaussian_mv::mean() const
```

Return Value

Returns the mean vector.

```
std::vector<double> gaussian_mv::matrix() const
```

Return Value

Returns the variance-covariance matrix.

Parent topic: *Distributions*

uniform (discrete)

Class is used for generation of uniformly distributed integer types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers uniformly distributed over the interval $[a, b)$, where a, b are the left and right bounds of the interval, respectively, and $a, b \in R; a < b$.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in R \\ 1, & x \geq b \end{cases}$$

class uniform

Syntax

```

namespace oneapi::mkl::rng {
template<typename Method = uniform_method::by_default>
class uniform<std::int32_t, Method> {
public:
    using method_type = Method;
    using result_type = std::int32_t;
    uniform();
    explicit uniform(std::int32_t a, std::int32_t b);
    std::int32_t a() const;
    std::int32_t b() const;
};
}

```

Template parameters

typename Method = oneapi::mkl::rng::uniform_method::by_default Transformation method, which will be used for generation. Supported types:

- oneapi::mkl::rng::uniform_method::by_default
- oneapi::mkl::rng::uniform_method::standard

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>uniform()</i>	Default constructor
<i>explicit uniform(std::int32_t a, std::int32_t b)</i>	Constructor with parameters
<i>std::int32_t a() const</i>	Method to obtain left bound <i>a</i>
<i>std::int32_t b() const</i>	Method to obtain right bound <i>b</i>

Member types

```
method_type = Method
```

Description

The type which defines transformation method for generation.

```
result_type = std::int32_t
```

Description

The type which defines type of generated random numbers.

Constructors

```
uniform()
```

Description

Default constructor for distribution, parameters set as $a = 0$, $b = \text{std::numeric_limits}<\text{std::int32_t}>::\text{max}()$.

```
uniform(std::int32_t a, std::int32_t b)
```

Description

Constructor with parameters. a is a left bound, b is a right bound, assume $a < b$.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $a \geq b$

Characteristics

```
a() const
```

Return Value

Returns the distribution parameter a - left bound.

```
b() const
```

Return Value

Returns the distribution parameter b - right bound.

Parent topic: *Distributions*

uniform_bits

Class is used for generation of uniformly distributed bits in 32/64-bit chunks.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide uniformly distributed bits in 32/64-bit chunks. It is designed to ensure each bit in the 32/64-bit chunk is uniformly distributed. Can be not supported by the specific engine.

class uniform_bits

Syntax

```

namespace oneapi::mkl::rng {
template<typename UIntType = std::uint32_t>
class uniform_bits {
public:
    using result_type = UIntType;
};
}

```

Template parameters

typename UIntType

Type of the produced values. Supported types:

- `std::uint32_t`
- `std::uint64_t`

Member types

```
uniform_bits::result_type = UIntType
```

Description

The type which defines type of generated random numbers.

Parent topic: *Distributions*

bits

Class is used for generation of underlying engine integer recurrence.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide integer random numbers. Each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated.

class bits

Syntax

```
namespace oneapi::mkl::rng {  
template<typename UIntType = std::uint32_t>  
class bits {  
public:  
    using result_type = UIntType;  
};  
}
```

Template parameters

typename UIntType

Type of the produced values. Supported types:

- `std::uint32_t`

Member types

```
bits::result_type = UIntType
```

Description

The type which defines type of generated random numbers.

Parent topic: *Distributions*

bernoulli

Class is used for generation of Bernoulli distributed integer types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers Bernoulli distributed with probability p of a single trial success, where $p \in R; 0 \leq p; p \leq 1$.

The probability distribution is given by:

$$P(X = 1) = p$$

$$P(X = 0) = 1 - p$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in R \\ 1, & x \geq 1 \end{cases}$$

class bernoulli

Syntax

```

namespace oneapi::mkl::rng {
template<typename IntType = std::int32_t, typename Method = bernoulli_method::by_default>
class bernoulli {
public:
    using method_type = Method;
    using result_type = IntType;
    bernoulli();
    explicit bernoulli(float p);
    float p() const;
};
}

```

Template parameters

typename IntType

Type of the produced values. Supported types:

- `std::int32_t`
- `std::uint32_t`

typename Method = oneapi::mkl::rng::bernoulli_method::by_default Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::bernoulli_method::by_default`
- `oneapi::mkl::rng::bernoulli_method::icdf`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>bernoulli()</i>	Default constructor
<i>explicit bernoulli(float p)</i>	Constructor with parameters
<i>float p() const</i>	Method to obtain probability p

Member types

```
bernoulli::method_type = Method
```

Description

The type which defines transformation method for generation.

```
bernoulli::result_type = IntType
```

Description

The type which defines type of generated random numbers.

Constructors

```
bernoulli::bernoulli()
```

Description

Default constructor for distribution, parameters set as $p = 0.5f$.

```
explicit bernoulli::bernoulli(float p)
```

Description

Constructor with parameters. p is a probability.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $p > 1.0f$, or $p < 0.0f$

Characteristics

```
float p() const
```

Return Value

Returns the distribution parameter p - probability.

Parent topic: *Distributions*

geometric

Class is used for generation of geometrically distributed integer types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers geometrically distributed with probability p of a single success trial, where $p \in R; 0 < p < 1$.

The probability distribution is given by:

$$P(X = k) = p * (1 - p)^k, k = \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & x \geq 0 \end{cases}$$

class geometric

Syntax

```
namespace oneapi::mkl::rng {
template<typename IntType = std::int32_t, typename Method = geometric_method::by_default>
class geometric {
public:
    using method_type = Method;
    using result_type = IntType;
    geometric();
    explicit geometric(float p);
    float p() const;
};
}
```

Template parameters

typename IntType

Type of the produced values. Supported types:

- `std::int32_t`
- `std::uint32_t`

typename Method = `oneapi::mkl::rng::geometric_method::by_default` Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::geometric_method::by_default`
- `oneapi::mkl::rng::geometric_method::icdf`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>geometric()</i>	Default constructor
<i>explicit geometric(float p)</i>	Constructor with parameters
<i>float p() const</i>	Method to obtain probability value

Member types

```
geometric::method_type = Method
```

Description

The type which defines transformation method for generation.

```
geometric::result_type = IntType
```

Description

The type which defines type of generated random numbers.

Constructors

```
geometric::geometric()
```

Description

Default constructor for distribution, parameters set as $p = 0.5$.

```
explicit geometric::geometric(float p)
```

Description

Constructor with parameters. p is a probability value.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $p \geq 1.0f$, or $p \leq 0.0f$

Characteristics

```
float geometric::p() const
```

Return Value

Returns the distribution parameter p - probability value.

Parent topic: *Distributions*

binomial

Class is used for generation of binomially distributed integer types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers binomially distributed with a number of independent Bernoulli trials m , and with probability p of a single trial success, where $p \in R; 0 \leq p \leq 1, m \in N$.

A binomially distributed variate represents the number of successes in m independent Bernoulli trials with probability of a single trial success p .

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1 - p)^{m-k}, & 0 \leq x < m, x \in R \\ 1, & x \geq m \end{cases}$$

class binomial

Syntax

```

namespace oneapi::mkl::rng {
template<typename IntType = std::int32_t, typename Method = binomial_method::by_default>
class binomial {
public:
    using method_type = Method;
    using result_type = IntType;
    binomial();
    explicit binomial(std::int32_t ntrial, double p);
    std::int32_t ntrial() const;
    double p() const;
};
}

```

Template parameters

typename IntType

Type of the produced values. Supported types:

- `std::int32_t`

typename Method = oneapi::mkl::rng::binomial_method::by_default Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::binomial_method::by_default`
- `oneapi::mkl::rng::binomial_method::btpe`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>binomial()</i>	Default constructor
<i>explicit binomial(std::int32_t ntrial, double p)</i>	Constructor with parameters
<i>std::int32_t ntrial() const</i>	Method to obtain number of independent trials <i>m</i>
<i>double p() const</i>	Method to obtain success probability of a single trial <i>p</i>

Member types

```
binomial::method_type = Method
```

Description

The type which defines transformation method for generation.

```
binomial::result_type = IntType
```

Description

The type which defines type of generated random numbers.

Constructors

```
binomial::binomial()
```

Description

Default constructor for distribution, parameters set as $m = 5$, $p = 0.5$.

```
explicit binomial::binomial(std::int32_t ntrial, double p)
```

Description

Constructor with parameters. *ntrial* is the number of independent trials, *p* is the success probability of a single trial.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $p > 1.0$, or $p < 0.0$, or $ntrial < 1$

Characteristics

```
std::int32_t binomial::ntrial() const
```

Return Value

Returns the distribution parameter *m* - number of independent trials.

```
double binomial::p() const
```

Return Value

Returns the distribution parameter p - success probability of a single trial.

Parent topic: *Distributions*

hypergeometric

Class is used for generation of hypergeometrically distributed integer types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers hypergeometrically distributed with lot size l , size of sampling s , and number of marked elements in the lot m , where $l, m, s \in \mathbb{N} \cup \{0\}; l \geq \max(s, m)$.

Consider a lot of l elements comprising m marked and $l - m$ unmarked elements. A trial sampling without replacement of exactly s elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of s elements contains exactly k marked elements.

The probability distribution is given by:

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, k \in \{\max(0, s + m - l), \dots, \min(s, m)\}.$$

The cumulative distribution function is as follows:

$$F_{l,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - l) \\ \sum_{k=\max(0, s+m-l)}^{\lfloor x \rfloor} \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, & \max(0, s + m - l) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

class hypergeometric

Syntax

```
namespace oneapi::mkl::rng {
template<typename IntType = std::int32_t, typename Method = hypergeometric_method::by_
↳default>
class hypergeometric {
public:
    using method_type = Method;
    using result_type = IntType;
    hypergeometric();
    explicit hypergeometric(std::int32_t l, std::int32_T s, std::int32_T m);
    std::int32_t s() const;
    std::int32_t m() const;
    std::int32_t l() const;
};
}
```

Template parameters

typename IntType

Type of the produced values. Supported types:

- `std::int32_t`
- `std::uint32_t`

typename Method = oneapi::mkl::rng::hypergeometric_method::by_default Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::hypergeometric_method::by_default`
- `oneapi::mkl::rng::hypergeometric_method::h2pe`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<code>hypergeometric()</code>	Default constructor
<code>explicit hypergeometric(std::int32_t l, std::int32_T s, std::int32_T m)</code>	Constructor with parameters
<code>std::int32_t s() const</code>	Method to obtain lot size
<code>std::int32_t m() const</code>	Method to obtain size of sampling without replacement
<code>std::int32_t l() const</code>	Method to obtain number of marked elements

Member types

```
hypergeometric::method_type = Method
```

Description

The type which defines transformation method for generation.

```
hypergeometric::result_type = IntType
```

Description

The type which defines type of generated random numbers.

Constructors

```
hypergeometric::hypergeometric()
```

Description

Default constructor for distribution, parameters set as $l = 1$, $s = 1$, $m = 1$.

```
explicit hypergeometric::hypergeometric(std::int32_t l, std::int32_T s, std::int32_T m)
```

Description

Constructor with parameters. l is a lot size, s is a size of sampling without replacement, m is a number of marked elements.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $s < 0$, or $m < 0$, or $l < (s > m ? s : m)$

Characteristics

```
std::int32_t hypergeometric::l() const
```

Return Value

Returns the distribution parameter l - lot size value.

```
std::int32_t hypergeometric::s() const
```

Return Value

Returns the distribution parameter s - size of sampling without replacement.

```
std::int32_t hypergeometric::m() const
```

Return Value

Returns the distribution parameter m - number of marked elements.

Parent topic: *Distributions*

poisson

Class is used for generation of Poisson distributed integer types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide random numbers Poisson distributed with distribution parameter λ , where $\lambda \in R; \lambda > 0$;

The probability distribution is given by:

$$P(X = k) = \frac{\lambda^k e^{-\lambda}}{k!}.$$

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

class poisson

Syntax

```

namespace oneapi::mkl::rng {
template<typename IntType = std::int32_t, typename Method = poisson_method::by_default>
class poisson {
public:
    using method_type = Method;
    using result_type = IntType;
    poisson();
    explicit poisson(double lambda);
    double lambda() const;
};
}

```

Template parameters

typename IntType

Type of the produced values. Supported types:

- `std::int32_t`

typename Method = oneapi::mkl::rng::poisson_method::by_default Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::poisson_method::by_default`
- `oneapi::mkl::rng::poisson_method::ptpe`
- `oneapi::mkl::rng::poisson_method::gaussian_icdf_based`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>poisson()</i>	Default constructor
<i>explicit poisson(double lambda)</i>	Constructor with parameters
<i>double lambda() const</i>	Method to obtain distribution parameter

Member types

```
poisson::method_type = Method
```

Description

The type which defines transformation method for generation.

```
poisson::result_type = IntType
```

Description

The type which defines type of generated random numbers.

Constructors

```
poisson::poisson()
```

Description

Default constructor for distribution, parameters set as $lambda = 0.5$.

```
explicit poisson::poisson(double lambda)
```

Description

Constructor with parameters. $lambda$ is a distribution parameter.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $lambda \leq 0.0$

Characteristics

```
double poisson::lambda() const
```

Return Value

Returns the distribution parameter *lambda*.

Parent topic: *Distributions*

poisson_v

Class is used for generation of Poisson distributed integer types random numbers with varying mean.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide n random numbers Poisson distributed, with distribution parameter λ_i , where $\lambda_i \in R; \lambda_i > 0; i = 1, \dots, n$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k e^{-\lambda_i}}{k!}, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

class poisson_v

Syntax

```
namespace oneapi::mkl::rng {
template<typename IntType = std::int32_t, typename Method = poisson_v_method::by_default>
class poisson_v {
public:
    using method_type = Method;
    using result_type = IntType;
    explicit poisson_v(std::vector<double> lambda);
    std::vector<double> lambda() const;
};
}
```

Template parameters

typename IntType

Type of the produced values. Supported types:

- `std::int32_t`

typename Method = `oneapi::mkl::rng::poisson_v_method::by_default` Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::poisson_v_method::by_default`
- `oneapi::mkl::rng::poisson_v_method::gaussian_icdf_based`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<code>explicit poisson_v(std::vector<double> lambda)</code>	Constructor with parameters
<code>std::vector<double> lambda() const</code>	Method to obtain distribution parameter

Member types

```
poisson_v::method_type = Method
```

Description

The type which defines transformation method for generation.

```
poisson_v::result_type = IntType
```

Description

The type which defines type of generated random numbers.

Constructors

```
explicit poisson_v::poisson_v(std::vector<double> lambda)
```

Description

Constructor with parameters. *lambda* is a distribution parameter.

Throws

oneapi::mkl::invalid_argument Exception is thrown when *lambda.size()* ≤ 1

Characteristics

```
double poisson_v::lambda() const
```

Return Value

Returns the distribution parameter *lambda*.

Parent topic: *Distributions*

negative_binomial

Class is used for generation of negative binomially distributed integer types random numbers.

Description

The class object is used in the *oneapi::mkl::rng::generate()* function to provide random numbers negative binomially distributed with distribution parameters *a* and *p*, where $p, a \in R; 0 \leq p \leq 1, a > 0$.

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1-p)^k, k \in \{0, 1, 2, \dots\}$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^k p^a (1-p)^k, & x \geq 0, x \in R \\ 0, & x < 0 \end{cases}$$

class negative_binomial

Syntax

```
namespace oneapi::mkl::rng {
template<typename IntType = std::int32_t, typename Method = negative_binomial_method::by_
↳ default>
class negative_binomial {
public:
```

(continues on next page)

(continued from previous page)

```

using method_type = Method;
using result_type = IntType;
negative_binomial();
explicit negative_binomial(double a, double p);
double a() const;
double p() const;
};
}

```

Template parameters

typename IntType

Type of the produced values. Supported types:

- `std::int32_t`
- `std::uint32_t`

typename **Method** = **oneapi::mkl::rng::negative_binomial_method::by_default** Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::negative_binomial_method::by_default`
- `oneapi::mkl::rng::negative_binomial_method::nbar`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<i>negative_binomial()</i>	Default constructor
<i>explicit negative_binomial(double a, double p)</i>	Constructor with parameters
<i>double a() const</i>	Method to obtain the first distribution parameter <i>a</i>
<i>double p() const</i>	Method to obtain the second distribution parameter <i>p</i>

Member types

```
negative_binomial::method_type = Method
```

Description

The type which defines transformation method for generation.

```
negative_binomial::result_type = IntType
```

Description

The type which defines type of generated random numbers.

Constructors

```
negative_binomial::negative_binomial()
```

Description

Default constructor for distribution, parameters set as $a = 0.1$, $p = 0.5$.

```
explicit negative_binomial::negative_binomial(double a, double p)
```

Description

Constructor with parameters. a is the first distribution parameter, p is the second distribution parameter.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $p \geq 1.0$, or $p \leq 0.0$, or $a \leq 0.0$

Characteristics

```
double negative_binomial::a() const
```

Return Value

Returns the distribution parameter a - the first distribution parameter.

```
double negative_binomial::p() const
```

Return Value

Returns the distribution parameter p - the second distribution parameter.

Parent topic: *Distributions*

multinomial

Class is used for generation of multinomially distributed integer types random numbers.

Description

The class object is used in the `oneapi::mkl::rng::generate()` function to provide n random numbers multinomially distributed, with independent trials $(ntrial, m)$ and possible mutually exclusive outcomes k , with corresponding probabilities p_i , where $p_i \in R; 0 \leq p_i \leq 1; m, k \in N$.

The probability distribution is given by:

$$P(X_1 = x_1, \dots, X_k = x_k) = \frac{m!}{\prod_{i=1}^k x_i!} \prod_{i=1}^k p_i^{x_i}, 0 \leq x_i \leq m, \sum_{i=1}^k x_i = m$$

class multinomial

Syntax

```
namespace oneapi::mkl::rng {
template<typename IntType = std::int32_t, typename Method = multinomial_method::by_
↳default>
class multinomial {
public:
    using method_type = Method;
    using result_type = IntType;
    explicit multinomial(double ntrial, std::vector<double> p);
    std::int32_t ntrial() const;
    std::vector<double> p() const;
};
}
```

Template parameters

typename IntType

Type of the produced values. Supported types:

- `std::int32_t`
- `std::uint32_t`

typename Method = oneapi::mkl::rng::multinomial_method::by_default Transformation method, which will be used for generation. Supported types:

- `oneapi::mkl::rng::multinomial_method::by_default`
- `oneapi::mkl::rng::multinomial_method::poisson_icdf_based`

See description of the methods in *Distributions methods template parameter*.

Class Members

Routine	Description
<code>explicit multinomial(double ntrial, std::vector<double> p)</code>	Constructor with parameters
<code>std::int32_t ntrial() const</code>	Method to obtain number of independent trials
<code>std::vector<double> p() const</code>	Method to obtain probability vector of possible outcomes

Member types

```
multinomial::method_type = Method
```

Description

The type which defines the transformation method for generation.

```
multinomial::result_type = IntType
```

Description

The type which defines the type of generated random numbers.

Constructors

```
explicit multinomial(double ntrial, std::vector<double> p)
```

Description

Constructor with parameters. *ntrial* is a number of independent trials, *p* is a probability vector.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $ntrial < 0$, or $p.size() < 1$

Characteristics

```
std::int32_t multinomial::ntrial() const
```

Return Value

Returns the distribution parameter *ntrial*.

```
std::vector<double> multinomial::p() const
```

Return Value

Returns the distribution parameter *p*.

11.2.5 Summary Statistics

The oneMKL provides a set of *Summary Statistics routines* that compute basic statistical estimates for single and double precision multi-dimensional datasets.

Summary Statistics

Definitions

The oneMKL Summary Statistics domains consists of:

- Dataset structure. The structure consolidates the information of a multi-dimensional dataset (see detailed description in *dataset*).
- Computation routines. The routines are represented as free functions (see detailed description for each routine in *Summary Statistics Routines*):
 - Raw and central sums / moments up to the fourth order
 - Variation coefficient
 - Skewness and excess kurtosis (further referred as kurtosis)
 - Minimum and maximum

Refer to *oneMKL Summary Statistics Usage Model*.

oneMKL Summary Statistics Usage Model

Description

A typical algorithm for summary statistics is as follows:

1. Create and initialize an object for dataset.
2. Call the summary statistics routine to calculate the appropriate estimate.

The following example demonstrates how to calculate mean values for a 3-dimensional dataset filled with random numbers. For dataset creation, the *make_dataset* helper function is used.

Buffer-based example

```
#include <iostream>
#include <vector>

#include "CL/sycl.hpp"
#include "oneapi/mkl/stats.hpp"

int main() {
    sycl::queue queue;
```

(continues on next page)

(continued from previous page)

```

const size_t n_observations = 1000;
const size_t n_dims = 3;
std::vector<float> x(n_observations * n_dims);
// fill x storage with random numbers
for(int i = 0; i < n_dims, i++) {
    for(int j = 0; j < n_observations; j++) {
        x[j + i * n_observations] = float(std::rand()) / float(RAND_MAX);
    }
}
//create buffer for dataset
sycl::buffer<float, 1> x_buf(x.data(), x.size());
// create buffer for mean values
sycl::buffer<float, 1> mean_buf(n_dims);
// create oneapi::mkl::stats::dataset
auto dataset = oneapi::mkl::stats::make_dataset<oneapi::mkl::stats::layout::row_
↳major>(n_dims, n_observations, x_buf);

oneapi::mkl::stats::mean(queue, dataset, mean_buf);

// create host accessor for mean_buf to print results
auto acc = mean_buf.template get_access<sycl::access::mode::read>();

for(int i = 0; i < n_dims; i++) {
    std::cout << "Mean value for dimension " << i << ": " << acc[i] << std::endl;
}
return 0;
}

```

USM-based example

```

#include <iostream>
#include <vector>

#include "CL/sycl.hpp"
#include "oneapi/mkl/stats.hpp"

int main() {
    sycl::queue queue;

    const size_t n_observations = 1000;
    const size_t n_dims = 3;

    sycl::usm_allocator<float, sycl::usm::alloc::shared> allocator(queue);

    std::vector<float, decltype(allocator)> x(n_observations * n_dims, allocator);
    // fill x storage with random numbers

```

(continues on next page)

(continued from previous page)

```

for(int i = 0; i < n_dims, i++) {
    for(int j = 0; j < n_observations; j++) {
        x[j + i * n_observations] = float(std::rand()) / float(RAND_MAX);
    }
}
std::vector<float, decltype(allocator)> mean_buf(n_dims, allocator);
// create oneapi::mkl::stats::dataset
auto dataset = oneapi::mkl::stats::make_dataset<oneapi::mkl::stats::layout::row_
↪major>(n_dims, n_observations, x);

sycl::event event = oneapi::mkl::stats::mean(queue, dataset, mean);
event.wait();
for(int i = 0; i < n_dims; i++) {
    std::cout << "Mean value for dimension " << i << ": " << mean[i] << std::endl;
}
return 0;
}

```

USM usage

You can also use USM with raw pointers by using the `sycl::malloc_shared/malloc_device` functions.

Parent topic: *Summary Statistics*

dataset

The structure consolidates the information of a multi-dimensional dataset.

Description

The `dataset` struct object is used in *Summary Statistics Routines* as a multi-dimensional data storage. `dataset` struct contains information about observations matrix and its size (dimensions x observations), observations weights and indices for dimensions (defines dimensions to be processed).

structure dataset (Buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<layout ObservationsLayout, typename Type>
    struct dataset<ObservationsLayout, sycl::buffer<Type, 1>> {

        explicit dataset(std::int64_t n_dims_, std::int64_t n_observations_,
            sycl::buffer<Type, 1> observations_, sycl::buffer<Type, 1> weights_ = {0}
↪,
            sycl::buffer<std::int64_t, 1> indices_ = {0}) :
            n_dims(n_dims_), n_observations(n_observations_),
            observations(observations_),

```

(continues on next page)

(continued from previous page)

```

        weights(weights_), indices(indices_) {};

    std::int64_t n_dims;
    std::int64_t n_observations;
    sycl::buffer<Type, 1> observations;
    sycl::buffer<Type, 1> weights = {0};
    sycl::buffer<std::int64_t, 1> indices = {0};
    static constexpr layout layout = ObservationsLayout;
};
}

```

Template parameters

typename Type Type of the multi-dimensional data. Supported types:

- float
- double

oneapi::mkl::stats::layout ObservationsLayout Type of the multi-dimensional data layout. Supported types:

- oneapi::mkl::stats::layout::row_major
- oneapi::mkl::stats::layout::col_major

Struct Members

Routine	Description
<i>explicit dataset(std::int64_t n_dims_, std::int64_t n_observations_, sycl::buffer<Type, 1> observations_, sycl::buffer<Type, 1> weights_ = {0}, sycl::buffer<std::int64_t, 1> indices_ = {0})</i>	Constructor

Constructors

```
explicit dataset::dataset(std::int64_t n_dims_, std::int64_t n_observations_,
    sycl::buffer<Type, 1> observations_,
    sycl::buffer<Type, 1> weights_ = {0},
    sycl::buffer<std::int64_t, 1> indices_ = {0})
```

Description

Constructor with parameters.

- *n_dims_* is the number of dimensions
- *n_observations_* is the number of observations
- *observations_* is the matrix of observations
- *weights_* is an optional parameter, represents array of weights for observations (of size *n_observations_*). If the parameter is not specified, each observation is assigned a weight equal 1.
- *indices_* is an optional parameter, represents array of dimensions that are processed (of size *n_dims_*). If the parameter is not specified, all dimensions are processed.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $n_dims_ \leq 0$, or $n_observations_ \leq 0$, or $observations_get_count() == 0$

structure dataset (USM version)

Syntax

```
namespace oneapi::mkl::stats {
template<layout ObservationsLayout, typename Type>
    struct dataset<Type*, ObservationsLayout> {
        explicit dataset(std::int64_t n_dims_, std::int64_t n_observations_, Type*
↪observations_,
            Type* weights_ = nullptr, std::int64_t* indices_ = nullptr) :
            n_dims(n_dims_), n_observations(n_observations_),
            observations(observations_),
            weights(weights_), indices(indices_) {};

        std::int64_t n_dims;
        std::int64_t n_observations;
        Type* observations;
        Type* weights = nullptr;
        std::int64_t* indices = nullptr;
        static constexpr layout layout = ObservationsLayout;
    };
}
```

Template parameters

typename Type Type of the multi-dimensional data. Supported types:

- float
- double

oneapi::mkl::stats::layout ObservationsLayout Type of the multi-dimensional data layout. Supported types:

- oneapi::mkl::stats::layout::row_major
- oneapi::mkl::stats::layout::col_major

Struct Members

Routine	Description
<i>explicit dataset(std::int64_t n_dims_, std::int64_t n_observations_, Type* observations_, Type* weights_ = nullptr, std::int64_t* indices_ = nullptr)</i>	Constructor

Constructors

```
explicit dataset::dataset(std::int64_t n_dims_, std::int64_t n_observations_,
    Type* observations_,
    Type* weights_ = nullptr,
    std::int64_t* indices_ = nullptr)
```

Description

Constructor with parameters.

- *n_dims_* is the number of dimensions
- *n_observations_* is the number of observations
- *observations_* is the matrix of observations
- *weights_* is an optional parameter, represents array of weights for observations (of size *n_observations_*). If the parameter is not specified, each observation is assigned a weight equal 1.
- *indices_* is an optional parameter, represents array of dimensions that are processed (of size *n_dims_*). If the parameter is not specified, all dimensions are processed.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $n_dims_ \leq 0$, or $n_observations_ \leq 0$, or $observations_ == nullptr$

Summary Statistics Routines

The oneMKL Summary Statistics routines calculate next estimates:

Routine	Description
<i>raw_sum</i>	Raw sums up to the fourth order
<i>central_sum</i>	Central sums up to the fourth order
<i>central_sum with provided mean</i>	Central sums up to the fourth order with provided mean
<i>mean</i>	Mean value
<i>raw_moment</i>	Raw moments up to the fourth order
<i>central_moment</i>	Central moments up to the fourth order
<i>central_moment with provided mean</i>	Central moments up to the fourth order with provided mean
<i>variation</i>	Variation coefficient
<i>variation with provided mean</i>	Variation coefficient with provided mean
<i>skewness</i>	Skewness value
<i>skewness with provided mean</i>	Skewness value with provided mean
<i>kurtosis</i>	Kurtosis value
<i>kurtosis with provided mean</i>	Kurtosis value with provided mean
<i>min</i>	Min value
<i>max</i>	Max value
<i>min_max</i>	Min and max values

Parent topic: *Summary Statistics*

raw_sum

Entry point to compute raw sums up to the 4th order.

Description and Assumptions

The `oneapi::mkl::stats::raw_sum` function is used to compute an array of raw sums up to the 4th order (raw sums for each dataset's dimension).

raw_sum supports the following precisions for data:

T
float
double

raw_sum (Buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void raw_sum(sycl::queue& queue,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> sum,
        sycl::buffer<Type, 1> raw_sum_2 = {0},
        sycl::buffer<Type, 1> raw_sum_3 = {0},
        sycl::buffer<Type, 1> raw_sum_4 = {0});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

sum `sycl::buffer` array of sum values.

raw_sum_2 Optional parameter. `sycl::buffer` array of 2nd order raw sum values.

raw_sum_3 Optional parameter. `sycl::buffer` array of 3rd order raw sum values.

raw_sum_4 Optional parameter. `sycl::buffer` array of 4th order raw sum values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `sum.get_count() == 0 & raw_sum_2.get_count() == 0 & raw_sum_3.get_count() == 0 & raw_sum_4.get_count() == 0`, or dataset object is invalid

raw_sum (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event raw_sum(sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data,
        Type* sum,
        Type* raw_sum_2 = nullptr,
        Type* raw_sum_3 = nullptr,
        Type* raw_sum_4 = nullptr,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

sum Pointer to the array of sum values.

raw_sum_2 Optional parameter. Pointer to the array of the 2nd order raw sum values.

raw_sum_3 Optional parameter. Pointer to the array of the 3rd order raw sum values.

raw_sum_4 Optional parameter. Pointer to the array of the 2nd order raw sum values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `sum == nullptr & raw_sum_2 == nullptr & raw_sum_3 == nullptr & raw_sum_4 == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

central_sum

Entry point to compute central sums up to the 4th order.

Description and Assumptions

The `oneapi::mkl::stats::central_sum` function is used to compute an array of central sums up to the 4th order (central sums for each dataset's dimension).

`central_sum` supports the following precisions for data:

T
float
double

central_sum (Buffer version)

Syntax

```
namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
void central_sum(sycl::queue& queue,
const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
sycl::buffer<Type, 1> central_sum_2,
sycl::buffer<Type, 1> central_sum_3 = {0},
sycl::buffer<Type, 1> central_sum_4 = {0});
}
```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

central_sum_2 sycl::buffer array of 2nd order central sum values.

central_sum_3 Optional parameter. sycl::buffer array of 3rd order central sum values.

central_sum_4 Optional parameter. sycl::buffer array of 4th order central sum values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `central_sum_2.get_count() == 0 & central_sum_3.get_count() == 0 & central_sum_4.get_count() == 0`, or dataset object is invalid

central_sum (USM version)

Syntax

```
namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event central_sum(
        sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data,
        Type* central_sum_2,
        Type* central_sum_3 = nullptr,
        Type* central_sum_4 = nullptr,
        const std::vector<sycl::event> &dependencies = {});
}
```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

central_sum_2 Pointer to the array of the 2nd order central sum values.

central_sum_3 Optional parameter. Pointer to the array of the 3rd order central sum values.

central_sum_4 Optional parameter. Pointer to the array of the 2nd order central sum values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `central_sum_2 == nullptr & central_sum_3 == nullptr & central_sum_4 == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

central_sum with provided mean

Entry point to compute central sums up to the 4th order with the provided mean values.

Description and Assumptions

The `oneapi::mkl::stats::central_sum` function is used to compute an array of central sums up to the 4th order (central sums for each dataset's dimension) with the provided mean values.

central_sum with provided mean supports the following precisions for data:

T
float
double

central_sum with provided mean (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void central_sum(sycl::queue& queue,
                    sycl::buffer<Type, 1> mean,

```

(continues on next page)

(continued from previous page)

```

const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
sycl::buffer<Type, 1> central_sum_2,
sycl::buffer<Type, 1> central_sum_3 = {0},
sycl::buffer<Type, 1> central_sum_4 = {0});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean `sycl::buffer` to the array of provided mean values.

data Dataset which is used for computation.

Output Parameters

central_sum_2 `sycl::buffer` array of 2nd order central sum values.

central_sum_3 Optional parameter. `sycl::buffer` array of 3rd order central sum values.

central_sum_4 Optional parameter. `sycl::buffer` array of 4th order central sum values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `central_sum_2.get_count() == 0 & central_sum_3.get_count() == 0 & central_sum_4.get_count() == 0`, or `mean.get_count() == 0`, or `dataset` object is invalid

central_sum with provided mean (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event central_sum(sycl::queue& queue,
        Type* mean,
        const dataset<ObservationsLayout, Type*>& data,
        Type* central_sum_2,
        Type* central_sum_3 = nullptr,
        Type* central_sum_4 = nullptr,

```

(continues on next page)

(continued from previous page)

```

const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean Pointer to the array of provided mean values.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

central_sum_2 Pointer to the array of the 2nd order central sum values.

central_sum_3 Optional parameter. Pointer to the array of the 3rd order central sum values.

central_sum_4 Optional parameter. Pointer to the array of the 2nd order central sum values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `central_sum_2 == nullptr & central_sum_3 == nullptr & central_sum_4 == nullptr`, or `mean == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

mean

Entry point to compute mean values.

Description and Assumptions

The `oneapi::mkl::stats::mean` function is used to compute a mean array (mean value for each dataset's dimension).

mean supports the following precisions for data:

T
float
double

mean (buffer version)

Syntax

```
namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
void mean(sycl::queue& queue,
const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
sycl::buffer<Type, 1> mean);
}
```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

mean `sycl::buffer` array of mean values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `mean.get_count() == 0`, or dataset object is invalid

mean (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
sycl::event mean(sycl::queue& queue,
    const dataset<ObservationsLayout, Type*>& data,
    Type* mean,
    const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

mean Pointer to the array of mean values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `mean == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

raw_moment

Entry point to compute raw moments up to the 4th order.

Description and Assumptions

The `oneapi::mkl::stats::raw_moment` function is used to compute array of raw moments up to the 4th order (raw moments for each dataset's dimension).

raw_moment supports the following precisions for data:

T
float
double

oneapi::mkl::stats::raw_moment (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = fast, typename Type, layout ObservationsLayout>
    void raw_moment(sycl::queue& queue,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> mean,
        sycl::buffer<Type, 1> raw_moment_2 = {0},
        sycl::buffer<Type, 1> raw_moment_3 = {0},
        sycl::buffer<Type, 1> raw_moment_4 = {0});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

mean `sycl::buffer` array of mean values.

raw_moment_2 Optional parameter. `sycl::buffer` array of 2nd order raw moment values.

raw_moment_3 Optional parameter. `sycl::buffer` array of 3rd order raw moment values.

raw_moment_4 Optional parameter. `sycl::buffer` array of 4th order raw moment values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `mean.get_count() == 0 & raw_moment_2.get_count() == 0 & raw_moment_3.get_count() == 0 & raw_moment_4.get_count() == 0`, or dataset object is invalid

raw_moment (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event raw_moment(
        sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data,
        Type* mean,
        Type* raw_moment_2 = nullptr,
        Type* raw_moment_3 = nullptr,
        Type* raw_moment_4 = nullptr,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

mean Pointer to the array of mean values.

raw_moment_2 Optional parameter. Pointer to the array of the 2nd order raw moment values.

raw_moment_3 Optional parameter. Pointer to the array of the 3rd order raw moment values.

raw_moment_4 Optional parameter. Pointer to the array of the 2nd order raw moment values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `mean == nullptr & raw_moment_2 == nullptr & raw_moment_3 == nullptr & raw_moment_4 == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

central_moment

Entry point to compute central moments up to the 4th order.

Description and Assumptions

The `oneapi::mkl::stats::central_moment` function is used to compute an array of central moments up to the 4th order (central moments for each dataset's dimension).

central_moment supports the following precisions for data:

T
float
double

central_moment (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = oneapi::mkl::stats::method::fast, typename Type,
        layout ObservationsLayout>
    void central_moment(sycl::queue& queue,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> central_moment_2,
        sycl::buffer<Type, 1> central_moment_3 = {0},
        sycl::buffer<Type, 1> central_moment_4 = {0});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

central_moment_2 `sycl::buffer` array of 2nd order central moment values.

central_moment_3 Optional parameter. `sycl::buffer` array of 3rd order central moment values.

central_moment_4 Optional parameter. `sycl::buffer` array of 4th order central moment values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `central_moment_2.get_count() == 0` & `central_moment_3.get_count() == 0` & `central_moment_4.get_count() == 0`, or dataset object is invalid

central_moment (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event central_moment(sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data, Type* central_moment_2,
        Type* central_moment_3 = nullptr, Type* central_moment_4 = nullptr,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

central_moment_2 Pointer to the array of the 2nd order central moment values.

central_moment_3 Optional parameter. Pointer to the array of the 3rd order central moment values.

central_moment_4 Optional parameter. Pointer to the array of the 2nd order central moment values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `central_moment_2 == nullptr & central_moment_3 == nullptr & central_moment_4 == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

central_moment with provided mean

Entry point to compute central moments up to the 4th order with the provided mean values.

Description and Assumptions

The `oneapi::mkl::stats::central_moment` function is used to compute an array of central moments up to the 4th order (central moments for each dataset's dimension) with the provided mean values.

central_moment with provided mean supports the following precisions for data:

T
float
double

central_moment with provided mean (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void central_moment(sycl::queue& queue,
        sycl::buffer<Type, 1> mean,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> central_moment_2,
        sycl::buffer<Type, 1> central_moment_3 = {0},
        sycl::buffer<Type, 1> central_moment_4 = {0});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean `sycl::buffer` to the array of provided mean values.

data Dataset which is used for computation.

Output Parameters

central_moment_2 `sycl::buffer` array of 2nd order central moment values.

central_moment_3 Optional parameter. `sycl::buffer` array of 3rd order central moment values.

central_moment_4 Optional parameter. `sycl::buffer` array of 4th order central moment values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `central_moment_2.get_count() == 0 & central_moment_3.get_count() == 0 & central_moment_4.get_count() == 0`, or `mean.get_count() == 0`, or dataset object is invalid

central_moment with provided mean (USM version)

Syntax

```
namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event central_moment(sycl::queue& queue,
        Type* mean,
        const dataset<ObservationsLayout, Type*>& data,
        Type* central_moment_2,
        Type* central_moment_3 = nullptr,
        Type* central_moment_4 = nullptr,
        const std::vector<sycl::event> &dependencies = {});
}
```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean Pointer to the array of provided mean values.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

central_moment_2 Pointer to the array of the 2nd order central moment values.

central_moment_3 Optional parameter. Pointer to the array of the 3rd order central moment values.

central_moment_4 Optional parameter. Pointer to the array of the 2nd order central moment values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `central_moment_2 == nullptr & central_moment_3 == nullptr & central_moment_4 == nullptr` or `mean == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

variation

Entry point to compute variation.

Description and Assumptions

The `oneapi::mkl::stats::variation` function is used to compute a variation array (variation for each dataset's dimension).

variation supports the following precisions for data:

T
float
double

variation (buffer version)**Syntax**

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void variation(sycl::queue& queue,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> variation);
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- oneapi::mkl::stats::method::fast
- oneapi::mkl::stats::method::one_pass

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

variation sycl::buffer array of variation values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when variation.get_count() == 0, or dataset object is invalid

variation (USM version)**Syntax**

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event variation(sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data,
        Type* variation,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

variation Pointer to the array of variation values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `variation == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

variation with provided mean

Entry point to compute variation with the provided mean values.

Description and Assumptions

The `oneapi::mkl::stats::variation` function is used to compute an array of variation (variation for each dataset's dimension) with the provided mean values.

variation with provided mean supports the following precisions for data:

T
float
double

oneapi::mkl::stats::variation (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void variation(sycl::queue& queue, sycl::buffer<Type, 1> mean,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> variation);
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- oneapi::mkl::stats::method::fast

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean sycl::buffer to the array of provided mean values.

data Dataset which is used for computation.

Output Parameters

variation sycl::buffer array of variation values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when variation.get_count() == 0, or mean.get_count() == 0, or dataset object is invalid

variation with provided mean (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event variation(sycl::queue& queue,
        Type* mean,
        const dataset<ObservationsLayout, Type*>& data,
        Type* variation,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean Pointer to the array of provided mean values.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

variation Pointer to the array of the variation values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `variation == nullptr`, or `mean == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

skewness

Entry point to compute skewness.

Description and Assumptions

The `oneapi::mkl::stats::skewness` function is used to compute a skewness array (skewness for each dataset's dimension).

skewness supports the following precisions for data:

T
float
double

skewness (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void skewness(sycl::queue& queue,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> skewness);
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- oneapi::mkl::stats::method::fast
- oneapi::mkl::stats::method::one_pass

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

skewness sycl::buffer array of skewness values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when skewness.get_count() == 0, or dataset object is invalid

skewness (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event skewness(sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data,
        Type* skewness,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

skewness Pointer to the array of skewness values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `skewness == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

skewness with provided mean

Entry point to compute skewness with the provided mean values.

Description and Assumptions

The `oneapi::mkl::stats::skewness` function is used to compute an array of skewness (skewness for each dataset's dimension) with the provided mean values.

skewness with provided mean supports the following precisions for data:

T
float
double

skewness with provided mean (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void skewness(sycl::queue& queue,
                 sycl::buffer<Type, 1> mean,
                 const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
                 sycl::buffer<Type, 1> skewness);
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean `sycl::buffer` to the array of provided mean values.

data Dataset which is used for computation.

Output Parameters

skewness `sycl::buffer` array of skewness values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `skewness.get_count() == 0`, or `mean.get_count() == 0`, or `dataset` object is invalid

skewness with provided mean (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event skewness(sycl::queue& queue,
                       Type* mean,
                       const dataset<ObservationsLayout, Type*>& data,
                       Type* skewness,
                       const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean Pointer to the array of provided mean values.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

skewness Pointer to the array of the skewness values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `skewness == nullptr`, or `mean == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

kurtosis

Entry point to compute kurtosis.

Description and Assumptions

The `oneapi::mkl::stats::kurtosis` function is used to compute a kurtosis array (kurtosis for each dataset's dimension).

kurtosis supports the following precisions for data:

T
float
double

kurtosis (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
    template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void kurtosis(sycl::queue& queue,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> kurtosis);
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- oneapi::mkl::stats::method::fast
- oneapi::mkl::stats::method::one_pass

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

kurtosis sycl::buffer array of kurtosis values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when kurtosis.get_count() == 0, or dataset object is invalid

kurtosis (USM version)

Syntax

```

namespace oneapi::mkl::stats {
    template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event kurtosis(sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data,
        Type* kurtosis,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`
- `oneapi::mkl::stats::method::one_pass`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

kurtosis Pointer to the array of kurtosis values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `kurtosis == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

kurtosis with provided mean

Entry point to compute kurtosis with the provided mean values.

Description and Assumptions

The `oneapi::mkl::stats::kurtosis` function is used to compute an array of kurtosis (kurtosis for each dataset's dimension) with the provided mean values.

kurtosis with provided mean supports the following precisions for data:

T
float
double

kurtosis with provided mean (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type,
        layout ObservationsLayout>
void oneapi::mkl::stats::kurtosis(sycl::queue& queue,
sycl::buffer<Type, 1> mean,
const oneapi::mkl::stats::dataset<sycl::buffer<Type, 1>, ObservationsLayout>& data,
sycl::buffer<Type, 1> kurtosis);
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean `sycl::buffer` to the array of provided mean values.

data Dataset which is used for computation.

Output Parameters

kurtosis `sycl::buffer` array of kurtosis values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `kurtosis.get_count() == 0`, or `mean.get_count() == 0`, or `dataset` object is invalid

kurtosis with provided mean (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = fast, typename Type, layout ObservationsLayout>
sycl::event kurtosis(sycl::queue& queue,
Type* mean,
const dataset<ObservationsLayout, Type*>& data,
Type* kurtosis,

```

(continues on next page)

(continued from previous page)

```
    const std::vector<sycl::event> &dependencies = {});  
}
```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

mean Pointer to the array of provided mean values.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

kurtosis Pointer to the array of the kurtosis values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `kurtosis == nullptr`, or `mean == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

min

Entry point to compute min values.

Description and Assumptions

The `oneapi::mkl::stats::min` function is used to compute min arrays (min value for each dataset's dimension).

`min` supports the following precisions for data:

T
float
double

min (buffer version)

Syntax

```
namespace oneapi::mkl::stats {
template<method Method = fast, typename Type, layout ObservationsLayout>
void min(sycl::queue& queue,
const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
sycl::buffer<Type, 1> min);
}
```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

min `sycl::buffer` array of min values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `min.get_count() == 0`, or dataset object is invalid

min (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = fast, typename Type, layout ObservationsLayout>
    sycl::event min(sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data,
        Type* min,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

min Pointer to the array of min values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `min == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

max

Entry point to compute max values.

Description and Assumptions

The `oneapi::mkl::stats::max` function is used to compute a max values arrays (max value for each dataset's dimension).

max supports the following precisions for data:

T
float
double

max (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
void max(sycl::queue& queue,
const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
sycl::buffer<Type, 1> max);
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

max `sycl::buffer` array of max values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `max.get_count() == 0`, or dataset object is invalid

max (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
sycl::event max(sycl::queue& queue,
               const dataset<ObservationsLayout, Type*>& data,
               Type* max,
               const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

max Pointer to the array of max values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `max == nullptr`, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

min_max

Entry point to compute min and max values.

Description and Assumptions

The `oneapi::mkl::stats::min_max` function is used to compute min and max arrays (min and max values for each dataset's dimension).

min_max supports the following precisions for data:

T
float
double

min_max (buffer version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    void min_max(sycl::queue& queue,
        const dataset<ObservationsLayout, sycl::buffer<Type, 1>>& data,
        sycl::buffer<Type, 1> min,
        sycl::buffer<Type, 1> max);
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

Output Parameters

min `sycl::buffer` array of min values.

max `sycl::buffer` array of max values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when `min.get_count() == 0`, or `max.get_count() == 0`, or dataset object is invalid

min_max (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<method Method = method::fast, typename Type, layout ObservationsLayout>
    sycl::event min_max(sycl::queue& queue,
        const dataset<ObservationsLayout, Type*>& data,
        Type* min,
        Type* max,
        const std::vector<sycl::event> &dependencies = {});
}

```

Template Parameters

Method Method which is used for estimate computation. The specific values are as follows:

- `oneapi::mkl::stats::method::fast`

Type Data precision.

ObservationsLayout Data layout. The specific values are described in *dataset*.

Input Parameters

queue The queue where the routine should be executed.

data Dataset which is used for computation.

dependencies Optional parameter. List of events to wait for before starting computation, if any.

Output Parameters

min Pointer to the array of min values.

max Pointer to the array of max values.

Throws

oneapi::mkl::invalid_argument Exception is thrown when min == nullptr, or max == nullptr, or dataset object is invalid

Return Value

Output event to wait on to ensure computation is complete.

Parent topic: *Summary Statistics Routines*

Service Routines

Routine	Description
<i>make_dataset</i>	Creates a dataset from the provided parameters

Parent topic: *Summary Statistics*

make_dataset

Entry point to create a dataset from the provided parameters.

Description and Assumptions

The `oneapi::mkl::stats::make_dataset` function is used to create a dataset from the provided storage of the observations matrix, the number of dimensions and observations, and other parameters.

make_dataset supports the following precisions for data:

T
float
double

make_dataset (buffer version)

Syntax

```
namespace oneapi::mkl::stats {
template<layout ObservationsLayout = layout::row_major, typename Type>
  dataset<sycl::buffer<Type, 1>, ObservationsLayout> make_dataset(
    std::int64_t n_dims,
```

(continues on next page)

(continued from previous page)

```

std::int64_t n_observations,
sycl::buffer<Type, 1> observations,
sycl::buffer<Type, 1> weights = {0},
sycl::buffer<std::int64_t, 1> indices = {0});
}

```

Template Parameters

ObservationsLayout Data layout. The specific values are described in *dataset*.

Type Data precision.

Input Parameters

n_dims The number of dimensions.

n_observations The number of observations.

observations Matrix of observations.

weights Optional parameter. Array of weights of size `n_observations`. Elements of the array are non-negative members. If the parameter is not specified, each observation has weight equal to 1.

indices Optional parameter. Array of vector components that are processed. The size of the array is `n_dims`. If the parameter is not specified, all components are processed.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $n_dims \leq 0$, or $n_observations \leq 0$, or `observations.get_count() == 0`

Return Value

Dataset holding specified parameters.

make_dataset (USM version)

Syntax

```

namespace oneapi::mkl::stats {
template<layout ObservationsLayout = layout::row_major, typename Type>
dataset<Type*, ObservationsLayout> make_dataset(std::int64_t
n_dims, std::int64_t n_observations,
Type* observations, Type* weights = nullptr, std::int64_t* indices = nullptr);
}

```

Template Parameters

ObservationsLayout Data layout. The specific values are described in *dataset*.

Type Data precision.

Input Parameters

n_dims The number of dimensions.

n_observations The number of observations.

observations Matrix of observations.

weights Optional parameter. Array of weights of size `n_observations`. Elements of the array are non-negative members. If the parameter is not specified, each observation has weight equal to 1.

indices Optional parameter. Array of vector components that are processed. Size of array is `n_dims`. If the parameter is not specified, all components are processed.

Throws

oneapi::mkl::invalid_argument Exception is thrown when $n_dims \leq 0$, or $n_observations \leq 0$, or `observations == nullptr`

Return Value

Dataset holding specified parameters.

Parent topic: *Summary Statistics*

11.2.6 Vector Math

oneMKL *Vector Mathematics functions* (VM) compute a mathematical function of each of the vector elements. VM includes a set of functions (arithmetic, power, trigonometric, exponential, hyperbolic, special, and rounding) that operate on vectors of real and complex numbers.

Vector Math

Application programs that improve performance with VM include nonlinear programming software, computation of integrals, financial calculations, computer graphics, and many others.

VM functions fall into the following groups according to the operations they perform:

- *VM Mathematical Functions* compute values of mathematical functions, such as sine, cosine, exponential, or logarithm, on vectors stored contiguously in memory.
- *VM Service Functions* set/get the accuracy modes and the error codes, and create error handlers for mathematical functions.

The VM mathematical functions take an input vector as an argument, compute values of the respective function element-wise, and return the results in an output vector. All the VM mathematical functions can perform in-place operations, where the input and output arrays are at the same memory locations.

- *Special Value Notations*

Special Value Notations

This defines notations of special values for complex functions. The definitions are provided in text, tables, or formulas.

- $z, z1, z2$, etc. denote complex numbers.
- $i, i2=-1$ is the imaginary unit.
- $x, X, x1, x2$, etc. denote real imaginary parts.
- $y, Y, y1, y2$, etc. denote imaginary parts.
- **X and Y represent any finite positive IEEE-754 floating point** values, if not stated otherwise.
- **Quiet NaN and signaling NaN are denoted with QNaN and SNAN**, respectively.
- **The IEEE-754 positive infinities or floating-point numbers are** denoted with a + sign before X, Y, etc.
- **The IEEE-754 negative infinities or floating-point numbers are** denoted with a - sign before X, Y, etc.

CONJ(z) and CIS(z) are defined as follows:

$$\text{CONJ}(x+i \cdot y)=x-i \cdot y$$

$$\text{CIS}(y)=\cos(y)+i \cdot \sin(y).$$

The special value tables show the result of the function for the z argument at the intersection of the RE(z) column and the i *IM(z) row. If the function encounters a special point for the argument z , the lower part of this cell shows the special point and the VM status value for this element. An empty cell indicates that this argument is normal and the result is well-defined computationally.

Parent topic: *Vector Math*

VM Mathematical Functions

This section describes VM functions that compute values of mathematical functions on real and complex vector arguments with unit increment.

Each function is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data, as well as a description of the input/output arguments.

The input range of parameters is equal to the mathematical range of the input data type, unless the function description specifies input threshold values, which mark off the precision overflow, as follows:

- FLT_MAX denotes the maximum number representable in single precision real data type
- DBL_MAX denotes the maximum number representable in double precision real data type

The following tables list the available mathematical functions grouped by category.

Arithmetic Routines	Description
<i>add</i>	Adds vector elements
<i>sub</i>	Subtracts vector elements
<i>sqr</i>	Squares vector elements
<i>mul</i>	Multiplies vector elements
<i>mulbyconj</i>	Multiplies elements of one vector by conjugated elements of the second vector

continues on next page

Table 7 – continued from previous page

Arithmetic Routines	Description
<i>conj</i>	Conjugates vector elements
<i>abs</i>	Computes the absolute value of vector elements
<i>arg</i>	Computes the argument of vector elements
<i>linearfrac</i>	Performs linear fraction transformation of vectors
<i>fmod</i>	Performs element by element computation of the modulus function of vector a with respect to vector b
<i>remainder</i>	Performs element by element computation of the remainder function on the elements of vector a and the corresponding elements of vector b

Power and Root Routines	Description
<i>inv</i>	Inverts vector elements
<i>div</i>	Divides elements of one vector by elements of the second vector
<i>sqrt</i>	Computes the square root of vector elements
<i>invsqrt</i>	Computes the inverse square root of vector elements
<i>cbrt</i>	Computes the cube root of vector elements
<i>invcbrt</i>	Computes the inverse cube root of vector elements
<i>pow2o3</i>	Computes the cube root of the square of each vector element
<i>pow3o2</i>	Computes the square root of the cube of each vector element
<i>pow</i>	Raises each vector element to the specified power
<i>powx</i>	Raises each vector element to the constant power
<i>powr</i>	Computes a to the power b for elements of two vectors, where the elements of vector argument a are all non-negative
<i>hypot</i>	Computes the square root of sum of squares

Exponential and Logarithmic Routines	Description
<i>exp</i>	Computes the base e exponential of vector elements
<i>exp2</i>	Computes the base 2 exponential of vector elements
<i>exp10</i>	Computes the base 10 exponential of vector elements
<i>expm1</i>	Computes the base e exponential of vector elements decreased by 1
<i>ln</i>	Computes the natural logarithm of vector elements
<i>log2</i>	Computes the base 2 logarithm of vector elements
<i>log10</i>	Computes the base 10 logarithm of vector elements
<i>log1p</i>	Computes the natural logarithm of vector elements that are increased by 1
<i>logb</i>	Computes the exponents of the elements of input vector a

Trigonometric Routines	Description
<i>cos</i>	Computes the cosine of vector elements
<i>sin</i>	Computes the sine of vector elements
<i>sincos</i>	Computes the sine and cosine of vector elements
<i>cis</i>	Computes the complex exponent of vector elements (cosine and sine combined to complex value)
<i>tan</i>	Computes the tangent of vector elements
<i>acos</i>	Computes the inverse cosine of vector elements
<i>asin</i>	Computes the inverse sine of vector elements
<i>atan</i>	Computes the inverse tangent of vector elements

continues on next page

Table 10 – continued from previous page

Trigonometric Routines	Description
<i>atan2</i>	Computes the four-quadrant inverse tangent of ratios of the elements of two vectors
<i>cospi</i>	Computes the cosine of vector elements multiplied by π
<i>sinpi</i>	Computes the sine of vector elements multiplied by π
<i>tanpi</i>	Computes the tangent of vector elements multiplied by π
<i>acospi</i>	Computes the inverse cosine of vector elements divided by π
<i>asinpi</i>	Computes the inverse sine of vector elements divided by π
<i>atanpi</i>	Computes the inverse tangent of vector elements divided by π
<i>atan2pi</i>	Computes the four-quadrant inverse tangent of the ratios of the corresponding elements of two vectors divided by π
<i>cosd</i>	Computes the cosine of vector elements multiplied by $\pi/180$
<i>sind</i>	Computes the sine of vector elements multiplied by $\pi/180$
<i>tand</i>	Computes the tangent of vector elements multiplied by $\pi/180$

Hyperbolic Routines	Description
<i>cosh</i>	Computes the hyperbolic cosine of vector elements
<i>sinh</i>	Computes the hyperbolic sine of vector elements
<i>tanh</i>	Computes the hyperbolic tangent of vector elements
<i>acosh</i>	Computes the inverse hyperbolic cosine of vector elements
<i>asinh</i>	Computes the inverse hyperbolic sine of vector elements
<i>atanh</i>	Computes the inverse hyperbolic tangent of vector elements.

Special Routines	Description
<i>erf</i>	Computes the error function value of vector elements
<i>erfc</i>	Computes the complementary error function value of vector elements
<i>cdfnorm</i>	Computes the cumulative normal distribution function value of vector elements
<i>erfinv</i>	Computes the inverse error function value of vector elements
<i>erfcinv</i>	Computes the inverse complementary error function value of vector elements
<i>cdfnorminv</i>	Computes the inverse cumulative normal distribution function value of vector elements
<i>lgamma</i>	Computes the natural logarithm for the absolute value of the gamma function of vector elements
<i>tgamma</i>	Computes the gamma function of vector elements
<i>expint1</i>	Computes the exponential integral of vector elements

Rounding Routines	Description
<i>floor</i>	Rounds towards minus infinity
<i>ceil</i>	Rounds towards plus infinity
<i>trunc</i>	Rounds towards zero infinity
<i>round</i>	Rounds to nearest integer
<i>nearbyint</i>	Rounds according to current mode
<i>rint</i>	Rounds according to current mode and reports inexact result status
<i>modf</i>	Computes the integer and fractional parts
<i>frac</i>	Computes the fractional part

Miscellaneous Routines	Description
<i>copysign</i>	Returns vector of elements of one argument with signs changed to match other argument elements
<i>nextafter</i>	Returns vector of elements containing the next representable floating-point values following the values from the elements of one vector in the direction of the corresponding elements of another vector
<i>fdim</i>	Returns vector containing the differences of the corresponding elements of the vector arguments if the first is larger and +0 otherwise
<i>fmax</i>	Returns the larger of each pair of elements of the two vector arguments
<i>fmin</i>	Returns the smaller of each pair of elements of the two vector arguments
<i>maxmag</i>	Returns the element with the larger magnitude between each pair of elements of the two vector arguments
<i>minmag</i>	Returns the element with the smaller magnitude between each pair of elements of the two vector arguments

Parent topic: *Vector Math*

abs

Computes absolute value of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event abs(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<R,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event abs(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    R* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

abs supports the following precisions.

T	R
float	float
double	double
std::complex<float>	float
std::complex<double>	double

Description

The `abs(a)` function computes an absolute value of vector elements.

Argument	Result	Status code
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNaN	QNaN	
SNAN	QNaN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{abs}(a) = \text{hypot}(\text{RE}(a), \text{IM}(a)).$$

The `abs` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

acos

Computes inverse cosine of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event acos(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event acos(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

acos supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The acos(a) function computes inverse cosine of vector elements.

Argument	Result	Status code
+0	$+\pi/2$	
-0	$+\pi/2$	
+1	+0	
-1	$+\pi$	
$ a > 1$	QNAN	oneapi::mkl::vm::status::errdom

Notes:

- $\text{acos}(\text{CONJ}(a)) = \text{CONJ}(\text{acos}(a))$.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
    sycl::event acosh(
        sycl::queue& exec_queue,
        std::int64_t n,
        sycl::buffer<T,1>& a,
        sycl::buffer<T,1> y,
        oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
        oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event acosh(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

acosh supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The acosh(a) function computes inverse hyperbolic cosine (nonnegative) of vector elements.

Argument	Result	Status code
+1	+0

Notes:

- $\text{acosh}(\text{CONJ}(a)) = \text{CONJ}(\text{acosh}(a))$.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

acospi

Computes the inverse cosine of vector elements divided by π .

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event acospi(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event acospi(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

acospi supports the following precisions.

T
float
double

Description

The `acospi(a)` function computes the inverse cosine of vector elements divided by π . For an argument `a`, the function computes `acos(a)/ π` .

Argument	Result	Status code
+0	+1/2	
-0	+1/2	
+1	+0	
-1	+1	
$ a > 1$	QNAN	oneapi::mkl::vm::status::errdom
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$\bullet \infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

add

Performs element by element addition of vector a and vector b.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event add(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event add(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

add supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The `add(a, b)` function performs element by element addition of vector `a` and vector `b`.

Argument 1	Argument 2	Result	Status code
+0	+0	+0	
+0	-0	+0	
-0	+0	+0	
-0	-0	-0	
$+\infty$	$+\infty$	$+\infty$	
$+\infty$	$-\infty$	QNAN	
$-\infty$	$+\infty$	QNAN	
$-\infty$	$-\infty$	$-\infty$	
SNAN	any value	QNAN	
any value	SNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{add}(x_1+i*y_1, x_2+i*y_2) = (x_1+x_2) + i*(y_1+y_2)$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all $\text{RE}(x)$, $\text{RE}(y)$, $\text{IM}(x)$, $\text{IM}(y)$ arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, and sets the VM status code to `oneapi::mkl::vm::status::overflow` (overriding any possible `oneapi::mkl::vm::status::accuracy_warning` status).

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

arg

Computes argument of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event arg(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<R,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event arg(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    R* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

arg supports the following precisions.

T	R
std::complex<float>	float
std::complex<double>	double

Description

The `arg(a)` function computes argument of vector elements.

See *Special Value Notations* for the conventions used in the table below.

RE(a) i·IM(a)	$-\infty$	$-X$	-0	$+0$	$+X$	$+\infty$	NAN
$+i\cdot\infty$	$+3\cdot\pi/4$	$+\pi/2$	$+\pi/2$	$+\pi/2$	$+\pi/2$	$+\pi/4$	NAN
$+i\cdot Y$	$+\pi$		$+\pi/2$	$+\pi/2$		$+0$	NAN
$+i\cdot 0$	$+\pi$	$+\pi$	$+\pi$	$+0$	$+0$	$+0$	NAN
$-i\cdot 0$	$-\pi$	$-\pi$	$-\pi$	-0	-0	-0	NAN
$-i\cdot Y$	$-\pi$		$-\pi/2$	$-\pi/2$		-0	NAN
$-i\cdot\infty$	$-3\cdot\pi/4$	$-\pi/2$	$-\pi/2$	$-\pi/2$	$-\pi/2$	$-\pi/4$	NAN
$+i\cdot\text{NAN}$	NAN	NAN	NAN	NAN	NAN	NAN	NAN

Note

$\arg(a) = \text{atan2}(\text{IM}(a), \text{RE}(a))$

The `arg` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

Parent topic: *VM Mathematical Functions*

asin

Computes inverse sine of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event asin(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event asin(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

asin supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The asin(a) function computes inverse sine of vector elements.

Argument	Result	Status code
+0	+0	
-0	-0	
+1	$+\pi/2$	
-1	$-\pi/2$	
$ a > 1$	QNAN	oneapi::mkl::vm::status::errdom
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{asin}(a) = -i * \text{asinh}(i * z).$$

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

asinh

Computes inverse hyperbolic sine of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event asinh(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event asinh(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

asinh supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The asinh(a) function computes inverse hyperbolic sine of vector elements.

Argument	Result	Status code

The asinh(a) function does not generate any errors.

Notes:

- $\text{asinh}(\text{CONJ}(a)) = \text{CONJ}(\text{asinh}(a))$
- $\text{asinh}(-a) = -\text{asinh}(a)$.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

asinpi

Computes the inverse sine of vector elements divided by π .

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event asinpi(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event asinpi(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

asinpi supports the following precisions.

T
float
double

Description

The asinpi(a) function computes the inverse sine of vector elements divided by π . For an argument a, the function computes asinpi(a)/ π .

Argument	Result	Status code
+0	+0	
-0	-0	
+1	+1/2	
-1	-1/2	
a > 1	QNAN	oneapi::mkl::vm::status::errdom
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is oneapi::mkl::vm::mode::not_defined.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

atan

Computes inverse tangent of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event atan(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```

namespace oneapi::mkl::vm {
sycl::event atan(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm

```

atan supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The atan(a) function computes inverse tangent of vector elements.

Argument	Result	Status code
+0	+0	
-0	-0	
+∞	+π/2	
-∞	-π/2	
QNAN	QNAN	
SNAN	QNAN	

The atan function does not generate any errors.

Specifications for special values of the complex functions are defined according to the following formula

$$\operatorname{atan}(a) = -i \cdot \operatorname{atanh}(i \cdot a).$$

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event atan2(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event atan2(
    sycl::queue& exec_queue,
```

(continues on next page)

(continued from previous page)

```

std::int64_t n,
const T *a,
const T *b,
T* y,
std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm

```

ad2d supports the following precisions.

T
float
double

Description

The atan2(a, b) function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector are computed as the four-quadrant arctangent of $a[i] / b[i]$.

Argument 1	Argument 2	Result	Status code

SNAN	QNAN	QNAN	
SNAN	SNAN	QNAN	

The atan2(a, b) function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing 1st input vector of size n.

b The buffer b containing 2nd input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the 1st input vector of size n.

b Pointer b to the 2nd input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

atan2pi

Computes the four-quadrant inverse tangent of the ratios of the corresponding elements of two vectors divided by π .

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event atan2pi(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event atan2pi(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

atan2pi supports the following precisions.

T
float
double

Description

The $\text{atan2pi}(a, b)$ function computes the four-quadrant inverse tangent of the ratios of the corresponding elements of two vectors divided by π .

For the elements of the output vector y , the function computes the four-quadrant arctangent of a_i/b_i , with the result divided by π .

Argument 1	Argument 2	Result	Status code
$-\infty$	$-\infty$	$-3/4$	
$-\infty$	$b < +0$	$-1/2$	
$-\infty$	-0	$+1/2$	
$-\infty$	$+0$	$-1/2$

QNAN	QNAN	QNAN	
QNAN	SNAN	QNAN	
SNAN	QNAN	QNAN	
SNAN	SNAN	QNAN	

The $\text{atan2pi}(a, b)$ function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer *a* containing 1st input vector of size *n*.

b The buffer *b* containing 2nd input vector of size *n*.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer *a* to the 1st input vector of size *n*.

b Pointer *b* to the 2nd input vector of size *n*.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

atanh

Computes inverse hyperbolic tangent of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event atanh(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event atanh(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

atanh supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The $\text{atanh}(a)$ function computes inverse hyperbolic tangent of vector elements.

Argument	Result	Status code
+1	$+\infty$	oneapi::mkl::vm::status::sing
-1	$-\infty$	oneapi::mkl::vm::status::sing
$ a > 1$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
$+\infty$	$+\infty$	oneapi::mkl::vm::status::errdom
QNAN	QNAN

Notes:

- $\text{atanh}(\pm 1 \pm i \cdot 0) = \pm \infty \pm i \cdot 0$, and `oneapi::mkl::vm::status::sing` error is generated
- $\text{atanh}(\text{CONJ}(a)) = \text{CONJ}(\text{atanh}(a))$
- $\text{atanh}(-a) = -\text{atanh}(a)$.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

atanpi

Computes the inverse tangent of vector elements divided by π .

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
    sycl::event atanpi(
        sycl::queue& exec_queue,
        std::int64_t n,
        sycl::buffer<T,1>& a,
        sycl::buffer<T,1>& y,
        oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
    sycl::event atanpi(
        sycl::queue& exec_queue,
        std::int64_t n,
        const T *a,
        T* y,
        std::vector<sycl::event> const & depends = {},
        oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

`atanpi` supports the following precisions.

T
float
double

Description

The `atanpi(a)` function computes the inverse tangent of vector elements divided by π . For an argument `a`, the function computes `atan(a)/ π` .

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	+1/2	
$-\infty$	-1/2	
QNAN	QNAN	
SNAN	QNAN	

The `atanpi` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See `set_mode` function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the `set_mode` function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

cbrt

Computes a cube root of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event cbrt(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event cbrt(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

cbrt supports the following precisions.

T
float
double

Description

The `cbirt(a)` function computes a cube root of vector elements.

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
QNAN	QNAN	
SNAN	QNAN	
+0	+0	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer `y` containing the output vector of size `n`.

USM API:

y Pointer `y` to the output vector of size `n`.

return value (event) Event, signifying availability of computed output and status code(s).

cdfnorm

Computes the cumulative normal distribution function values of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event cdfnorm(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event cdfnorm(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

cdfnorm supports the following precisions.

T
float
double

Description

The `cdfnorm` function computes the cumulative normal distribution function values for elements of the input vector `a` and writes them to the output vector `y`.

The cumulative normal distribution function is defined as given by:

$$\text{cdfnorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt$$

Useful relations for these functions:

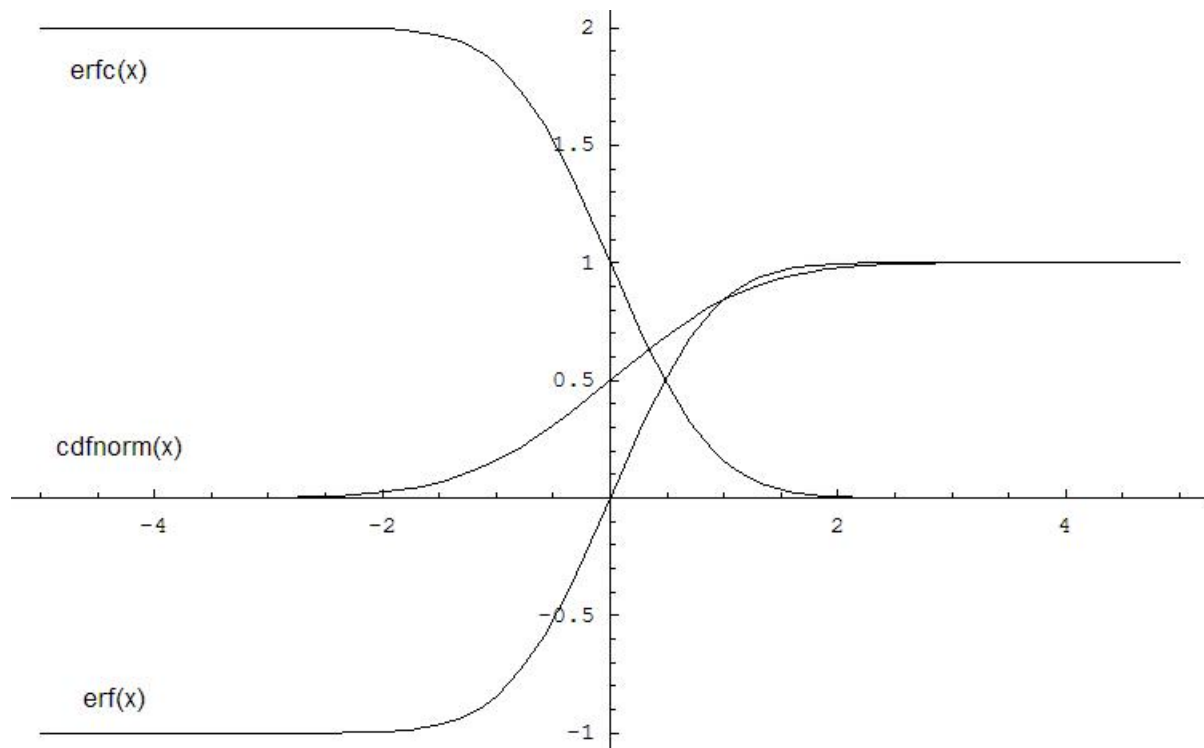

$$\text{erf}(x) + \text{erfc}(x) = 1$$

$$\begin{aligned} \text{cdfnorm}(x) &= \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) \\ &= 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right) \end{aligned}$$

where `erf` and `erfc` are the error and complementary error functions, respectively.

The following figure illustrates the relationships among the family of error functions (`erf`, `erfc`, `cdfnorm`).

cdfnorm Family Functions Relationship |

Argument	Result	Status code
<code>a < underflow</code>	<code>+0</code>	<code>oneapi::mkl::vm::status::underflow</code>
<code>+\infty</code>	<code>+1</code>	
<code>-\infty</code>	<code>+0</code>	
<code>QNAN</code>	<code>QNAN</code>	
<code>SNAN</code>	<code>QNAN</code>	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

cdfnorminv

Computes the inverse cumulative normal distribution function values of vector elements.

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event cdfnorminv(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event cdfnorminv(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

cdfnorminv supports the following precisions.

T
float
double

Description

The `cdfnorminv(a)` function computes the inverse cumulative normal distribution function values for elements of the input vector `a` and writes them to the output vector `y`.

The inverse cumulative normal distribution function is defined as given by:

$$\text{cdfnorminv}(x) = \text{cdfnorm}^{-1}(x)$$

where `cdfnorm(x)` denotes the cumulative normal distribution function.

Useful relations:

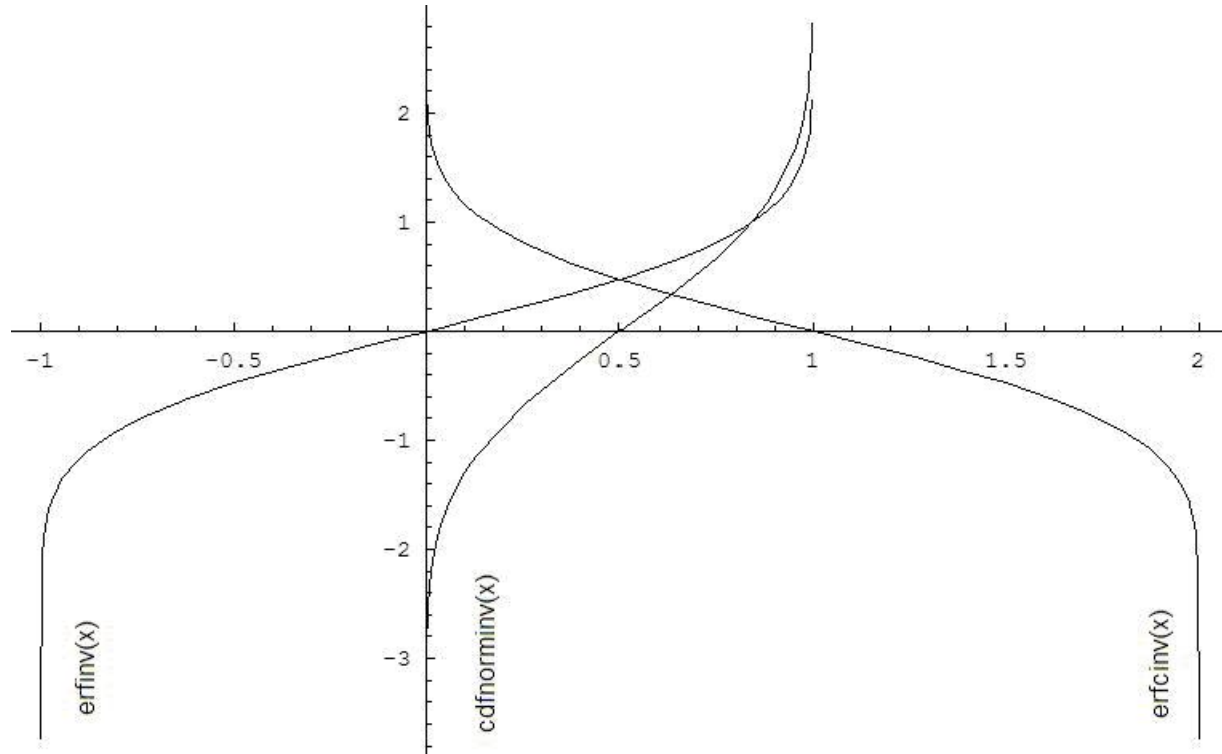

$$\operatorname{erfcinv}(x) = \operatorname{erfinv}(1 - x)$$

$$\begin{aligned} \operatorname{cdfnorminv}(x) &= \sqrt{2} \operatorname{erfinv}(2x - 1) \\ &= \sqrt{2} \operatorname{erfcinv}(2 - 2x) \end{aligned}$$

where $\operatorname{erfinv}(x)$ denotes the inverse error function and $\operatorname{erfcinv}(x)$ denotes the inverse complementary error function.

The following figure illustrates the relationships among erfinv family functions (erfinv , $\operatorname{erfcinv}$, $\operatorname{cdfnorminv}$).

$\operatorname{cdfnorminv}$ Family Functions Relationship |

Argument	Result	Status code

ceil

Computes an integer value rounded towards plus infinity for each vector element.

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event ceil(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event ceil(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm

```

ceil supports the following precisions.

T
float
double

Description

The ceil(a) function computes an integer value rounded towards plus infinity for each vector element.

$$y_i = \lceil a_i \rceil$$

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
QNAN	QNAN	
SNAN	QNAN	

The ceil function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

cis

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event cis(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<R,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event cis(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    R* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

cis supports the following precisions.

T	R
float	std::complex<float>
double	std::complex<double>

Description

The `cis(a)` function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Argument	Result	Status code
• 0	+1+i·0	
• 0	+1-i·0	
• ∞	QNAN+i·QNAN	oneapi::mkl::vm::status::errdom
• ∞	QNAN+i·QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN+i·QNAN	
SNAN	QNAN+i·QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

conj

Performs element by element conjugation of the vector.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event conj(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event conj(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

`conj` supports the following precisions.

T
std::complex<float>
std::complex<double>

Description

The conj function performs element by element conjugation of the vector.

No special values are specified. The conj function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

copysign

Returns vector of elements of one argument with signs changed to match other argument elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event copysign(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event copysign(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

copysign supports the following precisions.

T
float
double

Description

The `copysign(a, b)` function returns the first vector argument elements with the sign changed to match the sign of the second vector argument's corresponding elements.

Argument 1	Argument 2	Result	Status code
any value	positive value	+any value	
any value	negative value	-any value	

The `copysign(a, b)` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer `y` containing the output vector of size `n`.

USM API:

y Pointer `y` to the output vector of size `n`.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

cos

Computes cosine of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event cos(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event cos(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

cos supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The $\cos(a)$ function computes cosine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 213$ and $\text{abs}(a[i]) \leq 216$ for single and double precisions, respectively, are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Argument	Result	VM status code
+0	+1	
-0	+1	
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Cos}(z) = \text{Cosh}(i*z).$$

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

cosd

Computes the cosine of vector elements multiplied by $\pi/180$.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event cosd(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event cosd(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

cosd supports the following precisions.

T
float
double

Description

The `cosd(a)` function is a degree argument trigonometric function. It computes the cosine of vector elements multiplied by $\pi/180$. For an argument `a`, the function computes $\cos(\pi*a/180)$.

Note that arguments $\text{abs}(a_i) \leq 2^{24}$ for single precision or $\text{abs}(a_i) \leq 2^{52}$ for double precision, they belong to the *fast computational path*: trigonometric function arguments for which VM provides the best possible performance. Avoid arguments which do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

Argument	Result	Status code
+0	+1	
-0	+1	
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

Parent topic: *VM Mathematical Functions*

cosh

Computes hyperbolic cosine of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event cosh(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event cosh(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

cosh supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The cosh(a) function computes hyperbolic cosine of vector elements.

Data Type	Threshold Limitations on Input Parameters
single precision	$-\text{Log}(\text{FLT_MAX}) - \text{Log}2 <a[i] < \text{Log}(\text{FLT_MAX}) + \text{Log}2$

Notes:

- **The complex cosh(a) function sets the VM status code to oneapi::mkl::vm::status::overflow** in the case of overflow, that is, when RE(a), IM(a) are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\text{cosh}(\text{CONJ}(a)) = \text{CONJ}(\text{cosh}(a))$
- $\text{cosh}(-a) = \text{cosh}(a)$.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

cospi

Computes the cosine of vector elements multiplied by π .

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event cospi(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event cospi(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

cospi supports the following precisions.:

T
float
double

Description

The `cospi(a)` function computes the cosine of vector elements multiplied by π . For an argument `a`, the function computes $\cos(\pi*a)$.

Argument	Result	Status code
+0	+1	
-0	+1	
$n + 0.5$, for any integer n where $n + 0.5$ is representable	+0	
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

If arguments $\text{abs}(a_i) \leq 2^{22}$ for single precision or $\text{abs}(a_i) \leq 2^{51}$ for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments which do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer *a* containing input vector of size *n*.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer *a* to the input vector of size *n*.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

div

Performs element by element division of vector *a* by vector *b*

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event div(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event div(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

div supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The div(a, b) function performs element by element division of vector a by vector b.

Argument 1	Argument 2	Result	VM status code
X > +0	+0	+∞	oneapi::mkl::vm::status::sing
X > +0	-0	-∞	oneapi::mkl::vm::status::sing
X < +0	+0	-∞	oneapi::mkl::vm::status::sing
X < +0	-0	+∞	oneapi::mkl::vm::status::sing
+0	+0	QNAN	oneapi::mkl::vm::status::sing
-0	-0	QNAN	oneapi::mkl::vm::status::sing
X > +0	+∞	+0	
X > +0	-∞	-0	
+∞	+∞	QNAN	
-∞	-∞	QNAN	
QNAN	QNAN	QNAN	
SNAN	SNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Div}(x_1+i*y_1, x_2+i*y_2) = (x_1+i*y_1)*(x_2-i*y_2)/(x_2*x_2+y_2*y_2).$$

Overflow in a complex function occurs when x_2+i*y_2 is not zero, x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In that case, the function returns ∞ in that part of the result, and sets the VM status code to `oneapi::mkl::vm::status::overflow`.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing 1st input vector of size n.

b The buffer b containing 2nd input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the 1st input vector of size n.

b Pointer b to the 2nd input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

erf

Computes the error function value of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event erf(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```

namespace oneapi::mkl::vm {
sycl::event erf(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm

```

erf supports the following precisions.

T
float
double

Description

The erf function computes the error function values for elements of the input vector a and writes them to the output vector y.

The error function is defined as given by:

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Useful relations:

$$\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$$

where erfc is the complementary error function.

$$\Phi(x) = \frac{1}{2} \left(1 + \operatorname{erf} \left(\frac{x}{\sqrt{2}} \right) \right)$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

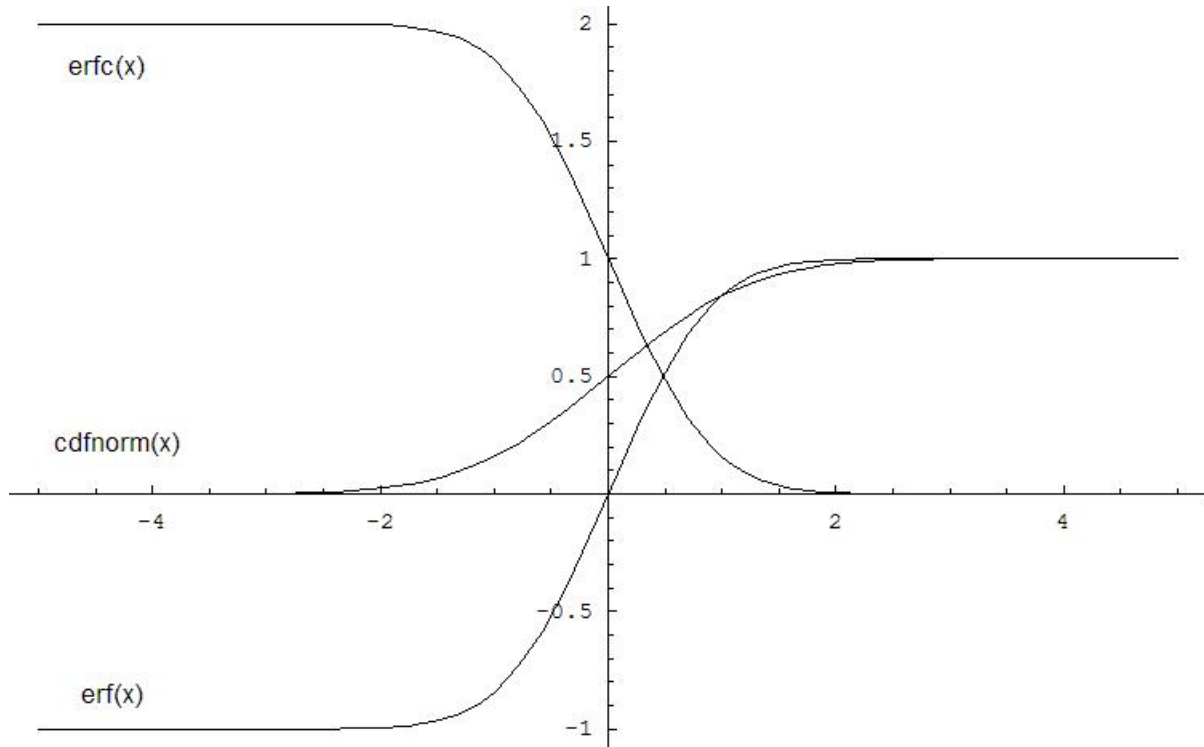

is the cumulative normal distribution function.

$$\Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1)$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$, respectively.

The following figure illustrates the relationships among erf family functions (erf, erfc, cdfnorm).

erf Family Functions Relationship |

Useful relations for these functions:

$$\operatorname{erf}(x) + \operatorname{erfc}(x) = 1$$

$$\begin{aligned} \operatorname{cdfnorm}(x) &= \frac{1}{2} \left(1 + \operatorname{erf} \left(\frac{x}{\sqrt{2}} \right) \right) \\ &= 1 - \frac{1}{2} \operatorname{erfc} \left(\frac{x}{\sqrt{2}} \right) \end{aligned}$$

erfc

Computes the complementary error function value of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event erfc(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event erfc(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

erfc supports the following precisions.

T
float
double

Description

The erfc function computes the complementary error function values for elements of the input vector a and writes them to the output vector y.

The complementary error function is defined as follows:

$$\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt$$

Useful relations:

$$\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$$

$$\Phi(x) = \frac{1}{2} \left(1 + \operatorname{erf} \left(\frac{x}{\sqrt{2}} \right) \right)$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

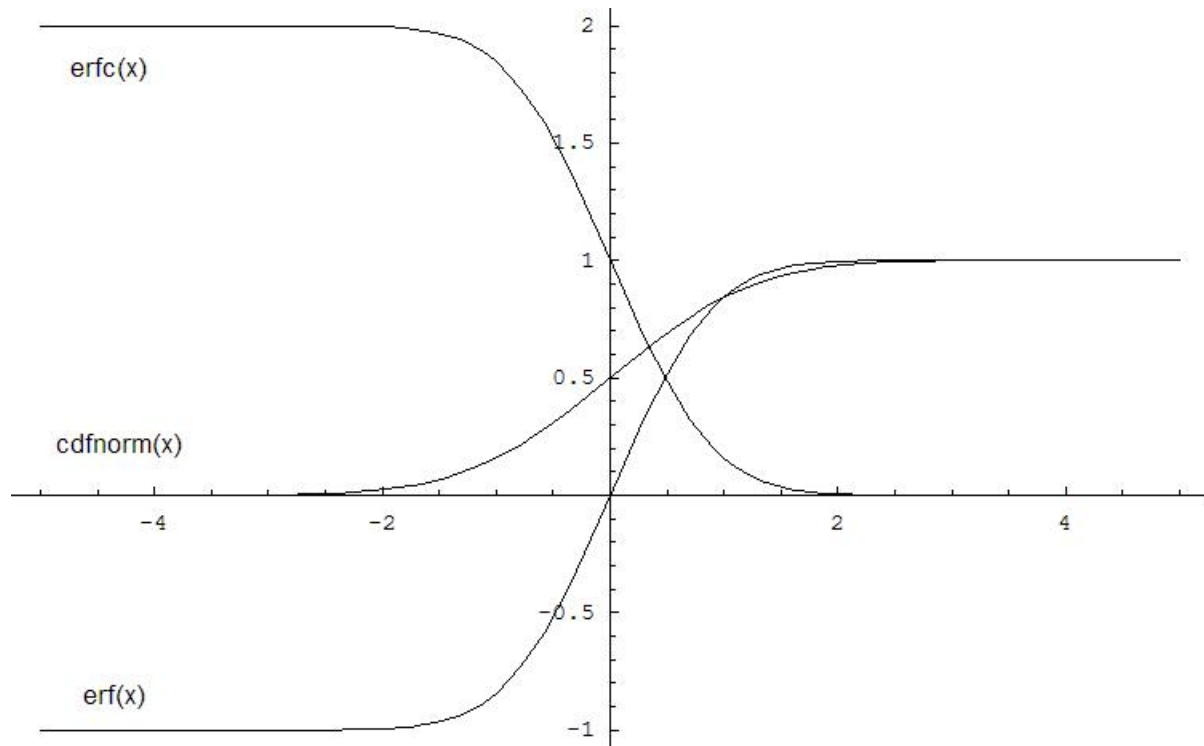

is the cumulative normal distribution function.

$$\Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1)$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$, respectively.

The following figure illustrates the relationships among erf family functions (erf, erfc, cdfnorm).

erfc Family Functions Relationship |

Useful relations for these functions:

$$\operatorname{erf}(x) + \operatorname{erfc}(x) = 1$$

$$\begin{aligned} \operatorname{cdfnorm}(x) &= \frac{1}{2} \left(1 + \operatorname{erf} \left(\frac{x}{\sqrt{2}} \right) \right) \\ &= 1 - \frac{1}{2} \operatorname{erfc} \left(\frac{x}{\sqrt{2}} \right) \end{aligned}$$

erfcinv

Computes the inverse complementary error function value of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event erfcinv(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event erfcinv(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

erfcinv supports the following precisions.

T
float
double

Description

The `erfcinv(a)` function computes the inverse complimentary error function values for elements of the input vector `a` and writes them to the output vector `y`.

The inverse complimentary error function is defined as given by:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

Useful relations for these functions:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\begin{aligned} \text{cdfnorminv}(x) &= \sqrt{2} \text{erfinv}(2x - 1) \\ &= \sqrt{2} \text{erfcinv}(2 - 2x) \end{aligned}$$

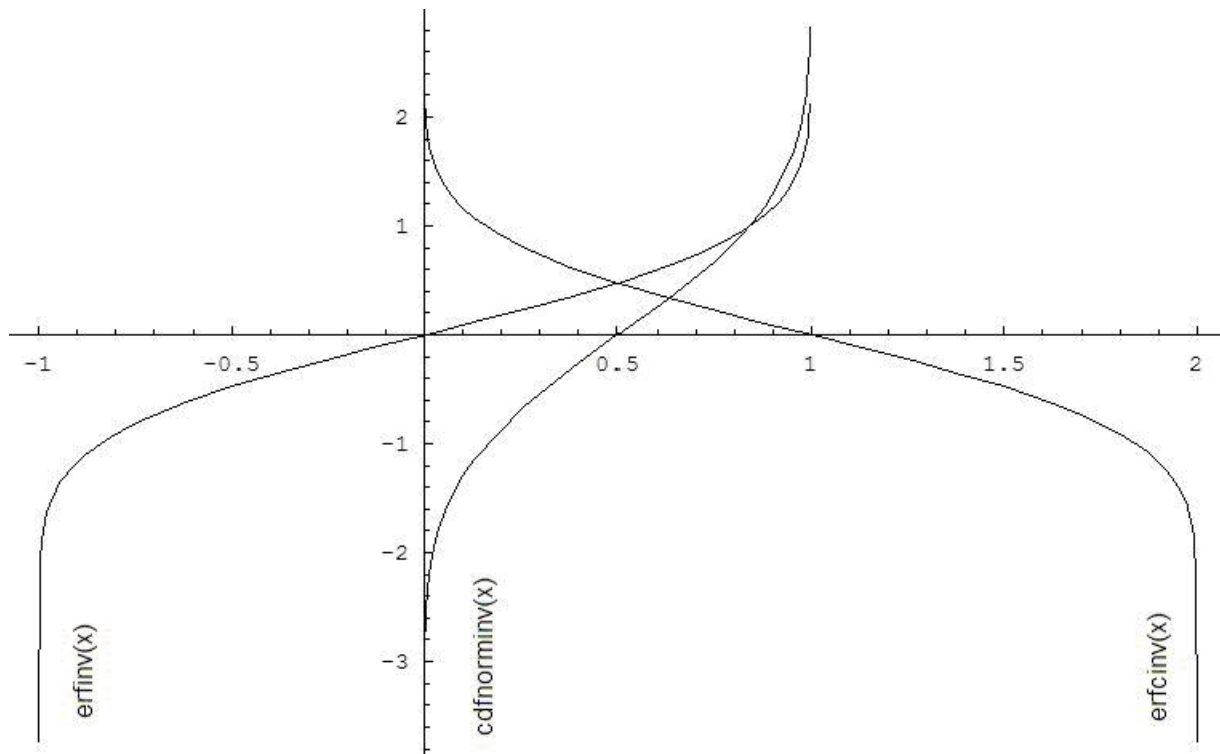

$$\text{erfinv}(x) = \text{erf}^{-1}(x)$$

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

where $\text{erf}(x)$ denotes the error function and $\text{erfinv}(x)$ denotes the inverse error function.

The following figure illustrates the relationships among `erfinv` family functions (`erfinv`, `erfcinv`, `cdfnorminv`).

    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

erfinv supports the following precisions.

T
float
double

Description

The `erfinv(a)` function computes the inverse error function values for elements of the input vector `a` and writes them to the output vector `y`.

$$y_i = \text{erf}^{-1}(a)$$

where $\text{erf}(x)$ is the error function defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Useful relations for these functions:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\begin{aligned} \text{cdfnorminv}(x) &= \sqrt{2} \text{erfinv}(2x - 1) \\ &= \sqrt{2} \text{erfcinv}(2 - 2x) \end{aligned}$$

$$\text{erf}^{-1}(x) = \text{erfc}^{-1}(1 - x)$$

where `erfc` is the complementary error function.

$$\Phi(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right)$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

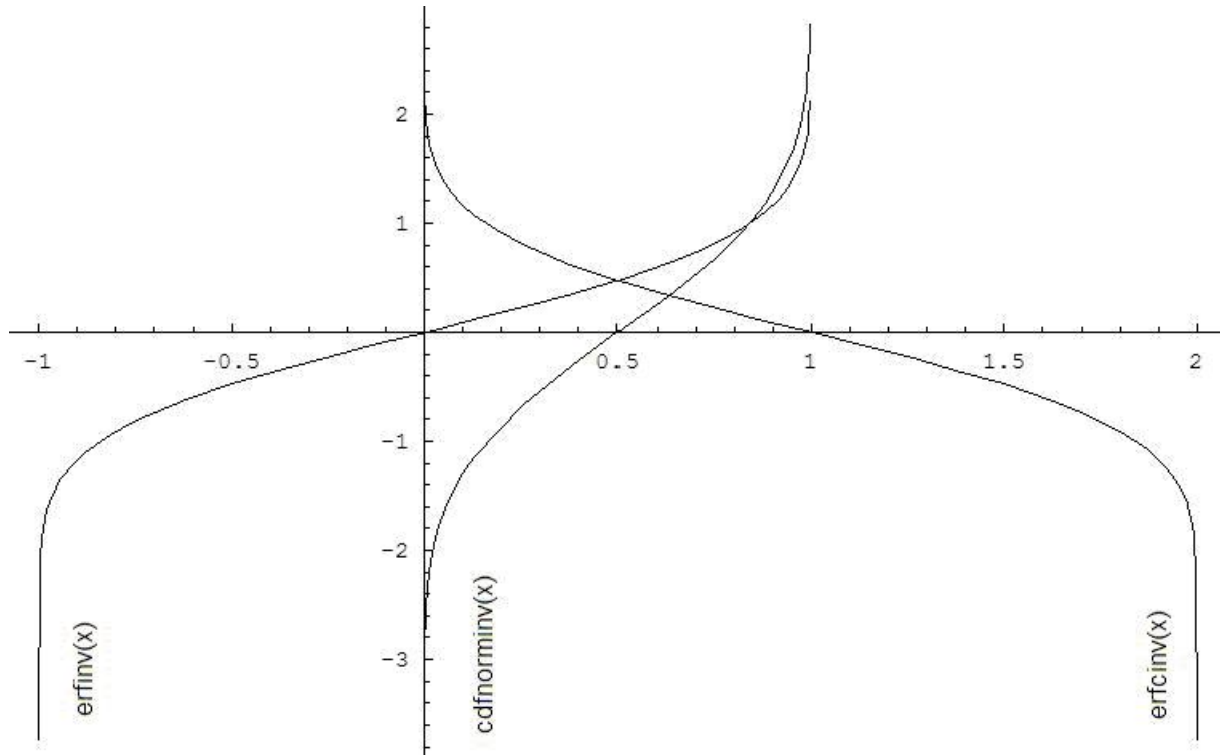

is the cumulative normal distribution function.

$$\Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1)$$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$, respectively.

The following figure illustrates the relationships among `erfinv` family functions (`erfinv`, `erfcinv`, `cdfnorminv`).

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

exp

Computes an exponential of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event exp(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event exp(
```

(continues on next page)

(continued from previous page)

```

sycl::queue& exec_queue,
std::int64_t n,
const T *a,
T* y,
std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm

```

exp supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The exp(a) function computes an exponential of vector elements.

Data Type	Threshold Limitations on Input Parameters
single precision	a[i] < Log(FLT_MAX)
double precision	a[i] < Log(DBL_MAX)

Argument	Result	Status code
+0	+1	
-0	+1	
a > overflow	+∞	oneapi::mkl::vm::status::overflow
a < underflow	+0	oneapi::mkl::vm::status::overflow
+∞	+∞	
-∞	+0	
QNAN	QNAN	
SNAN	QNAN	

+i·∞									
+i·Y									
+i·0									
-i·0									
-i·Y									
-i·∞									
+i·NAN									

Notes:

- The complex $\exp(z)$ function sets the VM status code to `oneapi::mkl::vm::status::overflow` in the case of overflow, that is, when both $\text{RE}(z)$ and $\text{IM}(z)$ are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer `y` containing the output vector of size `n`.

USM API:

y Pointer `y` to the output vector of size `n`.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

exp10

Computes the base 10 exponential of vector elements.

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event exp10(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event exp10(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

exp10 supports the following precisions.

T
float
double

Description

The exp10(a) function computes the base 10 exponential of vector elements.

Data Type	Threshold Limitations on Input Parameters
single precision	$a_i < \log_{10}(\text{FLT_MAX})$
double precision	$a_i < \log_{10}(\text{DBL_MAX})$

Argument	Result	VM status code
+0	+1	
-0	+1	
$a > \text{overflow}$	$+\infty$	<code>oneapi::mkl::vm::status::overflow</code>
$a < \text{underflow}$	+0	<code>oneapi::mkl::vm::status::underflow</code>
$+\infty$	$+\infty$	
$-\infty$	+0	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer *a* containing input vector of size *n*.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer *a* to the input vector of size *n*.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

exp2

Computes the base 2 exponential of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event exp2(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event exp2(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

exp2 supports the following precisions.

T
float
double

Description

The `exp2` function computes the base 2 exponential of vector elements.

Data Type	Threshold Limitations on Input Parameters
single precision	$a_i < \log_2(\text{FLT_MAX})$
double precision	$a_i < \log_2(\text{DBL_MAX})$

Argument	Result	Status code
+0	+1	
-0	+1	
$a > \text{overflow}$	$+\infty$	<code>oneapi::mkl::vm::status::overflow</code>
$a < \text{underflow}$	+0	<code>oneapi::mkl::vm::status::underflow</code>
$+\infty$	$+\infty$	
$-\infty$	+0	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

expint1

Computes the exponential integral of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event expint1(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event expint1(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

`expint1` supports the following precisions.

T
float
double

Description

The `expint1(a)` function computes the exponential integral of vector elements of the input vector `a` and writes them to the output vector `y`.

For positive real values `x`, this can be written as:

$$E_1(x) = \int_x^\infty \frac{e^{-t}}{t} dt = \int_1^\infty \frac{e^{-xt}}{t} dt$$

For negative real values `x`, the result is defined as NAN.

Argument	Result	Status code
<code>x < +0</code>	QNAN	<code>oneapi::mkl::vm::status::errdom</code>
<code>+0</code>	<code>+\infty</code>	<code>oneapi::mkl::vm::status::sing</code>
<code>-0</code>	<code>+\infty</code>	<code>oneapi::mkl::vm::status::sing</code>
<code>+\infty</code>	<code>+0</code>	
<code>-\infty</code>	QNAN	<code>oneapi::mkl::vm::status::errdom</code>
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

expm1

Computes an exponential of vector elements decreased by 1. $\exp(a[i]) - 1$

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event expm1(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event expm1(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

expm1 supports the following precisions.

T
float
double

Description

The expm1(a) function computes an exponential of vector elements decreased by 1.

Argument	Result	Status code
+0	+1	
-0	+1	
a > overflow	$+\infty$	oneapi::mkl::vm::status::overflow
$+\infty$	$+\infty$	
$-\infty$	-0	
QNaN	QNaN	
SNAN	QNaN	

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Log}(\text{FLT_MAX})$
double precision	$a[i] < \text{Log}(\text{DBL_MAX})$

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is oneapi::mkl::vm::mode::not_defined.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is oneapi::mkl::vm::mode::not_defined.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

fdim

Returns vector containing the differences of the corresponding elements of the vector arguments if the first is larger and +0 otherwise.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event fdim(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event fdim(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

`fdim` supports the following precisions.

T
float
double

Description

The `fdim(a, b)` function returns a vector containing the differences of the corresponding elements of the first and second vector arguments if the first element is larger, and `+0` otherwise.

Argument 1	Argument 2	Result	Status code
any	QNaN	QNaN	
any	SNAN	QNaN	
QNaN	any	QNaN	
SNAN	any	QNaN	

The `fdim(a, b)` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

floor

Computes an integer value rounded towards minus infinity for each vector element.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event floor(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event floor(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

floor supports the following precisions.

T
float
double

Description

The floor(a) function computes an integer value rounded towards minus infinity for each vector element.

$$y_i = \lfloor a_i \rfloor$$

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
QNAN	QNAN	
SNAN	QNAN	

The floor function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

fmax

Returns the larger of each pair of elements of the two vector arguments.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event fmax(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event fmax(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

`fmax` supports the following precisions.

T
float
double

Description

The `fmax(a, b)` function returns a vector with element values equal to the larger value from each pair of corresponding elements of the two vectors `a` and `b`: if `a < b` `fmax(a, b)` returns `b`, otherwise `fmax(a, b)` returns `a`.

Argument 1	Argument 2	Result	Status code
a not NAN	NAN	a	
NAN	b not NAN	b	
NAN	NAN	NAN	

The `fmax(a, b)` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

fmin

Returns the smaller of each pair of elements of the two vector arguments.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event fmin(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event fmin(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

`fmin` supports the following precisions.

T
float
double

Description

The `fmin(a, b)` function returns a vector with element values equal to the smaller value from each pair of corresponding elements of the two vectors `a` and `b`: if `a > b` `fmin(a, b)` returns `b`, otherwise `fmin(a, b)` returns `a`.

Argument 1	Argument 2	Result	Status code
a not NAN	NAN	a	
NAN	b not NAN	b	
NAN	NAN	NAN	

The `fmin(a, b)` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

Parent topic: *VM Mathematical Functions*

fmod

The `fmod` function performs element by element computation of the modulus function of vector **a** with respect to vector **b**.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event fmod(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event fmod(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
}
```

(continues on next page)

(continued from previous page)

```
} // namespace oneapi::mkl::vm
```

`fmod` supports the following precisions.

T
float
double

Description

The `fmod(a, b)` function computes the modulus function of each element of vector `a`, with respect to the corresponding elements of vector `b`:

$$a_i - b_i * \text{trunc}(a_i/b_i)$$

In general, the modulus function `fmod(ai, bi)` returns the value $a_i - n * b_i$ for some integer `n` such that if `bi` is nonzero, the result has the same sign as `ai` and a magnitude less than the magnitude of `bi`.

Argument 1	Argument 2	Result	Status code
a not NAN	± 0	NAN	oneapi::mkl::vm::status::sing
$\pm \infty$	b not NAN	NAN	oneapi::mkl::vm::status::sing
± 0	$b \neq 0$, not NAN	± 0	
a finite	$\pm \infty$	a	
NAN	b		
a	NAN	NAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: [VM Mathematical Functions](#)

frac

Computes a signed fractional part for each vector element.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event frac(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event frac(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
```

(continues on next page)

(continued from previous page)

```

std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm

```

frac supports the following precisions.

T
float
double

Description

The frac(a) function computes a signed fractional part for each vector element.

$$y_i = \begin{cases} a_i - \lfloor a_i \rfloor, & a_i \geq 0 \\ a_i - \lceil a_i \rceil, & a_i < 0 \end{cases}$$

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	+0	
$-\infty$	-0	
QNaN	QNaN	
SNAN	QNaN	

The frac function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

hypot

Computes a square root of sum of two squared elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event hypot(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event hypot(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

hypot supports the following precisions.

T
float
double

Description

The function `hypot(a, b)` computes a square root of sum of two squared elements.

Argument 1	Argument 2	Result	Status code
+0	+0	+0	
-0	-0	+0	
$+\infty$	any value	$+\infty$	
any value	$+\infty$	$+\infty$	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	any value	QNAN	
any value	QNAN	QNAN	

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{sqrt}(\text{FLT_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{FLT_MAX})$
double precision	$\text{abs}(a[i]) < \text{sqrt}(\text{DBL_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{DBL_MAX})$

The `hypot(a, b)` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

inv

Performs element by element inversion of the vector.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event inv(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event inv(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

inv supports the following precisions.

T
float
double

Description

The `inv(a)` function performs element by element inversion of the vector.

Argument	Result	VM status code
+0	$+\infty$	oneapi::mkl::vm::status::sing
-0	$-\infty$	oneapi::mkl::vm::status::sing
$+\infty$	+0	
$-\infty$	-0	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

Parent topic: *VM Mathematical Functions*

invcbrr

Computes an inverse cube root of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event invcbrr(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event invcbrr(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

`invcbrrt` supports the following precisions.

T
float
double

Description

The `invcbrrt(a)` function computes an inverse cube root of vector elements.

Argument	Result	Status code
+0	$+\infty$	<code>oneapi::mkl::vm::status::sing</code>
-0	$-\infty$	<code>oneapi::mkl::vm::status::sing</code>
$+\infty$	+0	
$-\infty$	-0	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

Parent topic: *VM Mathematical Functions*

invsqrt

Computes an inverse square root of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event invsqrt(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event invsqrt(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

`invsqrt` supports the following precisions.

T
float
double

Description

The `invsqrt(a)` function computes an inverse square root of vector elements.

Argument	Result	VM status code
$a < +0$	QNAN	<code>oneapi::mkl::vm::status::errdom</code>
$+0$	$+\infty$	<code>oneapi::mkl::vm::status::sing</code>
-0	$-\infty$	<code>oneapi::mkl::vm::status::sing</code>

lgamma

Computes the natural logarithm of the absolute value of gamma function for vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event lgamma(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event lgamma(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

`lgamma` supports the following precisions.

T
float
double

Description

The `lgamma(a)` function computes the natural logarithm of the absolute value of gamma function for elements of the input vector `a` and writes them to the output vector `y`. Precision overflow thresholds for the `lgamma` function are beyond the scope of this document. If the result does not meet the target precision, the function sets the VM status code to `oneapi::mkl::vm::status::overflow`.

Argument	Result	VM status code
+1	+0	
+2	+0	
+0	$+\infty$	<code>oneapi::mkl::vm::status::sing</code>
-0	$+\infty$	<code>oneapi::mkl::vm::status::sing</code>
negative integer	$+\infty$	<code>oneapi::mkl::vm::status::sing</code>
$-\infty$	$+\infty$	
$+\infty$	$+\infty$	
<code>a > overflow</code>	$+\infty$	<code>oneapi::mkl::vm::status::overflow</code>
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Parent topic: *VM Mathematical Functions*

linearfrac

Performs linear fraction transformation of vectors *a* and *b* with scalar parameters.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event linearfrac(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    T scalea,
    T shifta,
    T scaleb,
    T shiftb,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event linearfrac(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T scalea,
    T shifta,
```

(continues on next page)

(continued from previous page)

```

T scaleb,
T shiftb,
T* y,
std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm

```

linearfrac supports the following precisions.

T
float
double

Description

The linearfrac(a, b, scalea, shifta, scaleb, shiftb) function performs a linear fraction transformation of vector a by vector b with scalar parameters: scaling multipliers scalea, scaleb and shifting addends shifta, shiftb:

$$y[i] = (\text{scalea} \cdot a[i] + \text{shifta}) / (\text{scaleb} \cdot b[i] + \text{shiftb}), \quad i=1, 2, \dots, n$$

The linearfrac function is implemented in the EP accuracy mode only, therefore no special values are defined for this function. If used in HA or LA mode, linearfrac sets the VM status code to oneapi::mkl::vm::status::accuracy_warning. Correctness is guaranteed within the threshold limitations defined for each input parameter (see the table below); otherwise, the behavior is unspecified.

Threshold Limitations on Input Parameters
$2^{EMIN}/2 \leq \text{scalea} \leq 2^{(EMAX-2)}/2$
$2^{EMIN}/2 \leq \text{scaleb} \leq 2^{(EMAX-2)}/2$
$ \text{shifta} \leq 2^{EMAX-2}$
$ \text{shiftb} \leq 2^{EMAX-2}$
$2^{EMIN}/2 \leq a[i] \leq 2^{(EMAX-2)}/2$
$2^{EMIN}/2 \leq b[i] \leq 2^{(EMAX-2)}/2$
$a[i] \neq -(\text{shifta}/\text{scalea}) \cdot (1 - \delta_1), \quad \delta_1 \leq 2^{1-(p-1)}/2$
$b[i] \neq -(\text{shiftb}/\text{scaleb}) \cdot (1 - \delta_2), \quad \delta_2 \leq 2^{1-(p-1)}/2$

EMIN and EMAX are the minimum and maximum exponents and p is the number of significant bits (precision) for the corresponding data type according to the ANSI/IEEE Standard 754-2008 ([Bibliography](#)):

- for single precision $EMIN = -126, EMAX = 127, p = 24$
- for double precision $EMIN = -1022, EMAX = 1023, p = 53$

The thresholds become less strict for common cases with scalea=0 and/or scaleb=0:

- if scalea=0, there are no limitations for the values of a[i] and shifta.
- if scaleb=0, there are no limitations for the values of b[i] and shiftb.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer **a** containing 1st input vector of size **n**.

b The buffer **b** containing 2nd input vector of size **n**.

scalea Constant value for scaling multipliers of vector **a**

shifta Constant value for shifting addend of vector **a**

scaleb Constant value for scaling multipliers of vector **b**

shiftb**** Constant value for shifting addend of vector **b**

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The pointer **a** to the 1st input vector of size **n**.

b The pointer **b** to the 2nd input vector of size **n**.

scalea Constant value for scaling multipliers of vector **a**

shifta Constant value for shifting addend of vector **a**

scaleb Constant value for scaling multipliers of vector **b**

shiftb**** Constant value for shifting addend of vector **b**

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

In

Computes natural logarithm of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event ln(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event ln(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

In supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The $\ln(a)$ function computes natural logarithm of vector elements.

Argument	Result	Status code
+1	+0	
$a < +0$	QNAN	oneapi::mkl::vm::status::errdom
+0	$-\infty$	oneapi::mkl::vm::status::sing

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

log10

Computes the base 10 logarithm of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event log10(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event log10(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
}
```

(continues on next page)

(continued from previous page)

```
} // namespace oneapi::mkl::vm
```

log10 supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The log10(a) function computes the base 10 logarithm of vector elements.

Argument	Result	Status code
+1	+0

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

log1p

Computes a natural logarithm of vector elements that are increased by 1. $\log(a[i] + 1)$

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event log1p(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event log1p(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

log1p supports the following precisions.

T
float
double

Description

The log1p(a) function computes a natural logarithm of vector elements that are increased by 1.

Argument	Result	VM status code
-1	$-\infty$	oneapi::mkl::vm::status::sing
a < -1	QNAN	oneapi::mkl::vm::status::errdom
+0	+0	
-0	-0	
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
$+\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

log2

Computes the base 2 logarithm of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event log2(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event log2(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

log2 supports the following precisions.

T
float
double

Description

The $\log_2(a)$ function computes the base 2 logarithm of vector elements.

Argument	Result	Status code
+1	+0	
$a < +0$	QNAN	oneapi::mkl::vm::status::errdom
+0	$-\infty$	oneapi::mkl::vm::status::sing
-0	$-\infty$	oneapi::mkl::vm::status::sing
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
$+\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

logb

Computes the exponents of the elements of input vector a.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event logb(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event logb(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

logb supports the following precisions.

T
float
double

Description

The $\log_b(a)$ function computes the exponents of the elements of the input vector a . For each element a_i of vector a , this is the integral part of $\log_2|a_i|$. The returned value is exact and is independent of the current rounding direction mode.

Argument	Result	VM status code
+0	$+\infty$	oneapi::mkl::vm::status::errdom
-0	$-\infty$	oneapi::mkl::vm::status::errdom
$-\infty$	$+\infty$	
$+\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n .

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the 1st input vector of size n .

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n .

USM API:

y Pointer y to the output vector of size n .

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

maxmag

Returns the element with the larger magnitude between each pair of elements of the two vector arguments.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event maxmag(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event maxmag(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

maxmag supports the following precisions.

T
float
double

Description

The `maxmag(a, b)` function returns a vector with element values equal to the element with the larger magnitude from each pair of corresponding elements of the two vectors `a` and `b`:

- If $|a| > |b|$ `maxmag(a, b)` returns `a`, otherwise `maxmag(a, b)` returns `b`.
- If $|b| > |a|$ `maxmag(a, b)` returns `b`, otherwise `maxmag(a, b)` returns `a`.
- Otherwise `maxmag(a, b)` behaves like `fmax`.

Argument 1	Argument 2	Result	Status code
a not NAN	NAN	a	
NAN	b not NAN	b	
NAN	NAN	NAN	

The `maxmag(a, b)` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer `y` containing the output vector of size `n`.

USM API:

y Pointer `y` to the output vector of size `n`.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

minmag

Returns the element with the smaller magnitude between each pair of elements of the two vector arguments.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event minmag(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event minmag(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

minmag supports the following precisions.

T
float
double

Description

The `minmag(a, b)` function returns a vector with element values equal to the element with the smaller magnitude from each pair of corresponding elements of the two vectors `a` and `b`:

- If $|a| < |b|$ **minmag(a, b) returns a**, otherwise `minmag(a, b)` returns `b`.
- If $|b| < |a|$ **minmag(a, b) returns b**, otherwise `minmag(a, b)` returns `a`.
- Otherwise `minmag` behaves like `fmin`.

Argument 1	Argument 2	Result	Status code
a not NAN	NAN	a	
NAN	b not NAN	b	
NAN	NAN	NAN	

The `minmag(a, b)` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer `y` containing the output vector of size `n`.

USM API:

y Pointer `y` to the output vector of size `n`.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

modf

Computes a truncated integer value and the remaining fraction part for each vector element.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event modf(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    sycl::buffer<T,1>& z,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event modf(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    T* z,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

modf supports the following precisions.

T
float
double

Description

The `modf(a)` function computes a truncated integer value and the remaining fraction part for each vector element.

$$a_i \geq 0, \begin{cases} y_i = \lfloor a_i \rfloor \\ z_i = a_i - \lfloor a_i \rfloor \end{cases}$$

$$a_i < 0, \begin{cases} y_i = \lceil a_i \rceil \\ z_i = a_i - \lceil a_i \rceil \end{cases}$$

Argument	Result 1	Result 2	Status code
+0	+0	+0	
-0	-0	-0	
$+\infty$	$+\infty$	+0	
$-\infty$	$-\infty$	-0	
SNAN	QNAN	QNAN	
QNAN	QNAN	QNAN	

The `modf` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n* for truncated integer values.

z The buffer *z* containing the output vector of size *n* for remaining fraction parts.

USM API:

y Pointer *y* to the output vector of size *n* for truncated integer values.

z Pointer *z* to the output vector of size *n* for remaining fraction parts.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

Parent topic: *VM Mathematical Functions*

mul

Performs element by element multiplication of vector *a* and vector *b*.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event mul(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event mul(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
```

(continues on next page)

(continued from previous page)

```

oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm

```

mul supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The mul(a, b) function performs element by element multiplication of vector a and vector b.

Argument 1	Argument 2	Result	Status code
+0	+0	+0	
+0	-0	-0	
-0	+0	-0	
-0	-0	+0	
+0	+∞	QNAN	
+0	-∞	QNAN	
-0	+∞	QNAN	
-0	-∞	QNAN	
+∞	+0	QNAN	
+∞	-0	QNAN	
-∞	+0	QNAN	
-∞	-0	QNAN	
+∞	+∞	+∞	
+∞	-∞	-∞	
-∞	+∞	-∞	
-∞	-∞	+∞	
SNAN	any value	QNAN	
any value	SNAN	QNAN	
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{mul}(x_1+i*y_1, x_2+i*y_2) = (x_1*x_2-y_1*y_2) + i*(x_1*y_2+y_1*x_2)$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all RE(x), RE(y), IM(x), IM(y) arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, and sets the VM status code to oneapi::mkl::vm::status::overflow (overriding any possible oneapi::mkl::vm::status::accuracy_warning status).

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer **a** containing 1st input vector of size **n**.

b The buffer **b** containing 2nd input vector of size **n**.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer **a** to the 1st input vector of size **n**.

b Pointer **b** to the 2nd input vector of size **n**.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

mulbyconj

Performs element by element multiplication of vector a element and conjugated vector b element.

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event mulbyconj(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event mulbyconj(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

mulbyconj supports the following precisions.

T
std::complex<float>
std::complex<double>

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer **a** containing 1st input vector of size **n**.

b The buffer **b** containing 2nd input vector of size **n**.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer **a** to the 1st input vector of size **n**.

b Pointer **b** to the 2nd input vector of size **n**.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

nearbyint

Computes a rounded integer value in the current rounding mode for each vector element.

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event nearbyint(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event nearbyint(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm

```

nearbyint supports the following precisions.

T
float
double

Description

The nearbyint(a) function computes a rounded integer value in a current rounding mode for each vector element.

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
QNAN	QNAN	
SNAN	QNAN	

The nearbyint function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer *a* containing input vector of size *n*.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer *a* to the input vector of size *n*.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

nextafter

Returns vector of elements containing the next representable floating-point values following the values from the elements of one vector in the direction of the corresponding elements of another vector.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event nextafter(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event nextafter(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

nextafter supports the following precisions.

T
float
double

Description

The nextafter(a, b) function returns a vector containing the next representable floating-point values following the first vector argument elements in the direction of the second vector argument's corresponding elements.

Arguments/Results	Status code
Input vector argument element is finite and the corresponding result vector element value is infinite	oneapi::mkl::vm::status::overflow
Result vector element value is subnormal or zero, and different from the corresponding input vector argument element	oneapi::mkl::vm::status::underflow

Even though underflow or overflow can occur, the returned value is independent of the current rounding direction mode.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer **a** containing 1st input vector of size **n**.

b The buffer **b** containing 2nd input vector of size **n**.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer **a** to the 1st input vector of size **n**.

b Pointer **b** to the 2nd input vector of size **n**.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

pow

Computes a to the power b for elements of two vectors.

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event pow(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event pow(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

pow supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The pow(a, b) function computes a to the power b for elements of two vectors.

The real function pow has certain limitations on the input range of a and b parameters. Specifically, if a[i] is positive, then b[i] may be arbitrary. For negative a[i], the value of b[i] must be an integer (either positive or negative).

The complex function pow has no input range limitations.

QNaN	QNaN	QNaN	
QNaN	SNAN	QNaN	
SNAN	QNaN	QNaN	
SNAN	SNAN	QNaN	

* Overflow in a real function is supported only in the HA/LA accuracy modes. The overflow occurs when x and y are finite numbers, but the result is too large to fit the target precision. In this case, the function:

1. Returns ∞ in the result.
2. Sets the VM status code to `oneapi::mkl::vm::status::overflow`.

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all $RE(x)$, $RE(y)$, $IM(x)$, $IM(y)$ arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, and sets the VM status code to `oneapi::mkl::vm::status::overflow` (overriding any possible `oneapi::mkl::vm::status::accuracy_warning` status).

The complex double precision versions of this function are implemented in the EP accuracy mode only. If used in HA or LA mode, the functions set the VM status code to `oneapi::mkl::vm::status::accuracy_warning`.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing 1st input vector of size n.

b The buffer b containing 2nd input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the 1st input vector of size n.

b Pointer *b* to the 2nd input vector of size *n*.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

pow2o3

Computes the cube root of the square of each vector element.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event pow2o3(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event pow2o3(
    sycl::queue& exec_queue,
```

(continues on next page)

(continued from previous page)

```

std::int64_t n,
const T *a,
T* y,
std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm

```

pow2o3 supports the following precisions.

T
float
double

Description

The pow2o3(a) function computes the cube root of the square of each vector element.

Argument	Result	Status code
+0	+0	
-0	+0	
$+\infty$	$+\infty$	
$-\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

} // namespace oneapi::mkl::vm
```

pow3o2 supports the following precisions.

T
float
double

Description

The pow3o2(a) function computes the square root of the cube of each vector element.

Data Type	Threshold Limitations on Input Parameters
single precision	$ a_i < (\text{FLT_MAX})^{2/3}$
double precision	$ a_i < (\text{FLT_MAX})^{2/3}$

Argument	Result	VM status code
$a < +0$	QNAN	oneapi::mkl::vm::status::errdom
+0	+0	
-0	-0	
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
$+\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is oneapi::mkl::vm::mode::not_defined.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer `y` containing the output vector of size `n`.

USM API:

y Pointer `y` to the output vector of size `n`.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

power

Computes `a` to the power `b` for elements of two vectors, where the elements of vector argument `a` are all non-negative.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event power(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event power(
    sycl::queue& exec_queue,
    std::int64_t n,
```

(continues on next page)

(continued from previous page)

```

const T *a,
const T *b,
T* y,
std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

powr supports the following precisions.

T
float
double

Description

The powr(a, b) function raises each element of vector a by the corresponding element of vector b. The elements of a are all nonnegative ($a_i \geq 0$).

Data Type	Threshold Limitations on Input Parameters
single precision	$a_i < (\text{FLT_MAX})^{1/\hat{b} \hat{i}}$
double precision	$a_i < (\text{DBL_MAX})^{1/\hat{b} \hat{i}}$

Special values and VM status code treatment for v?Powr function are the same as for pow, unless otherwise indicated in this table:

Argument 1	Argument 2	Result	Status code
$a < 0$	any value b	NAN	oneapi::mkl::vm::status::errdom
$0 < a < \infty$	± 0	1	
± 0	$-\infty < b < 0$	$+\infty$	
± 0	$-\infty$	$+\infty$	
± 0	$b > 0$	+0	
1	$-\infty < b < \infty$	1	
± 0	± 0	NAN	
$+\infty$	± 0	NAN

SNAN	QNAN	QNAN	oneapi::mkl::vm::status::errdom
SNAN	SNAN	QNAN	oneapi::mkl::vm::status::errdom

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer **a** containing 1st input vector of size **n**.

b The buffer **b** containing 2nd input vector of size **n**.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer **a** to the 1st input vector of size **n**.

b Pointer **b** to the 2nd input vector of size **n**.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

powx

Computes vector a to the scalar power b.

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event powx(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    T b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event powx(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

powx supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The `powx` function computes a to the power b for a vector a and a scalar b .

The real function `powx` has certain limitations on the input range of a and b parameters. Specifically, if $a[i]$ is positive, then b may be arbitrary. For negative $a[i]$, the value of b must be an integer (either positive or negative).

The complex function `powx` has no input range limitations.

Special values and VM status code treatment are the same as for the `pow` function.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing 1st input vector of size n .

b Fixed value of power b .

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the 1st input vector of size n .

b Fixed value of power b .

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n .

USM API:

y Pointer y to the output vector of size n .

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

remainder

Performs element by element computation of the remainder function on the elements of vector a and the corresponding elements of vector b.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event remainder(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event remainder(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    const T *b,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm
```

remainder supports the following precisions.

T
float
double

Description

The `remainder(a)` function computes the remainder of each element of vector `a`, with respect to the corresponding elements of vector `b`: compute the values of `n` such that

$$n = a_i - n*b_i$$

where `n` is the integer nearest to the exact value of a_i/b_i . If two integers are equally close to a_i/b_i , `n` is the even one. If `n` is zero, it has the same sign as a_i .

Argument 1	Argument 2	Result	VM status code
a not NAN	± 0	NAN	oneapi::mkl::vm::status::errdom
$\pm\infty$	b not NAN	NAN	
± 0	$b \neq 0$, not NAN	± 0	
a finite	$\pm\infty$	a	
NAN	b	NAN	
a	NAN	NAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing 1st input vector of size `n`.

b The buffer `b` containing 2nd input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the 1st input vector of size `n`.

b Pointer `b` to the 2nd input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

rint

Computes a rounded integer value in the current rounding mode.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event rint(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event rint(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

`rint` supports the following precisions.

T
float
double

Description

The rint(a) function computes a rounded floating-point integer value using the current rounding mode for each vector element.

The rounding mode affects the results computed for inputs that fall between consecutive integers. For example:

- $f(0.5) = 0$, for rounding modes set to round to nearest round toward zero or to minus infinity.
- $f(0.5) = 1$, for rounding modes set to plus infinity.
- $f(-1.5) = -2$, for rounding modes set to round to nearest or to minus infinity.
- $f(-1.5) = -1$, for rounding modes set to round toward zero or to plus infinity.

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
QNaN	QNaN	
SNAN	QNaN	

The rint function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

round

Computes a value rounded to the nearest integer for each vector element.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event round(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event round(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

`round` supports the following precisions.

T
float
double

Description

The `round(a)` function computes a value rounded to the nearest integer for each vector element. Input elements that are halfway between two consecutive integers are always rounded away from zero regardless of the rounding mode.

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
QNAN	QNAN	
SNAN	QNAN	

The `round(a)` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

sin

Computes sine of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event sin(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event sin(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

`sin` supports the following precisions.

T
float
double
<code>std::complex<float></code>
<code>std::complex<double></code>

Description

The `sin(a)` function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 213$ and $\text{abs}(a[i]) \leq 216$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Argument	Result	VM status code
+0	+0	
-0	-0	
$+\infty$	QNAN	<code>oneapi::mkl::vm::status::errdom</code>
$-\infty$	QNAN	<code>oneapi::mkl::vm::status::errdom</code>
QNAN	QNAN	
SNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Sin}(z) = -i * \text{Sinh}(i * z).$$

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: [VM Mathematical Functions](#)

sincos

Computes sine and cosine of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
    sycl::event sincos(
        sycl::queue& exec_queue,
        std::int64_t n,
        sycl::buffer<T,1>& a,
        sycl::buffer<T,1>& y,
        sycl::buffer<T,1>& z,
        oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
        oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
    sycl::event sincos(
        sycl::queue& exec_queue,
        std::int64_t n,
```

(continues on next page)

(continued from previous page)

```

const T *a,
T* y,
T* z,
std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm

```

sincos supports the following precisions.

T
float
double

Description

The sincos(a) function computes sine and cosine of vector elements.

Note that arguments $abs(a[i]) \leq 213$ and $abs(a[i]) \leq 216$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Argument	Result 1	Result 2	Status code
+0	+0	+1

$-\infty$	QNAN	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	QNAN	
SNAN	QNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output sine vector of size n.

z The buffer z containing the output cosine vector of size n.

USM API:

y Pointer y to the output sine vector of size n.

z The buffer z containing the output cosine vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

sind

Computes the sine of vector elements multiplied by $\pi/180$.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event sind(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```

namespace oneapi::mkl::vm {
sycl::event sind(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm

```

sind supports the following precisions.

T
float
double

Description

The `sind(a)` function is a degree argument trigonometric function. It computes the sine of vector elements multiplied by $\pi/180$. For an argument `a`, the function computes $\sin(\pi*a/180)$.

Note that arguments $\text{abs}(a_i) \leq 2^{24}$ for single precision or $\text{abs}(a_i) \leq 2^{52}$ for double precision, they belong to the *fast computational path*: trigonometric function arguments for which VM provides the best possible performance. Avoid arguments which do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See `set_mode` function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the `create_error_handler` function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: *VM Mathematical Functions*

sinh

Computes hyperbolic sine of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event sinh(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1> y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```

namespace oneapi::mkl::vm {
sycl::event sinh(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm

```

`sinh` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The `sinh(a)` function computes hyperbolic sine of vector elements.

Data Type	Threshold Limitations on Input Parameters
single precision	$-\text{Log}(\text{FLT_MAX}) - \text{Log}(2) < a[i] < \text{Log}(\text{FLT_MAX}) + \text{Log}(2)$
double precision	$-\text{Log}(\text{DBL_MAX}) - \text{Log}(2) < a[i] < \text{Log}(\text{DBL_MAX}) + \text{Log}(2)$

Argument	Result	Status code
+0	+0	
-0	-0	
a > overflow	$+\infty$	oneapi::mkl::vm::status::overflow
a < -overflow	$-\infty$	oneapi::mkl::vm::status::overflow
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
QNAN	QNAN	
SNAN	QNAN	

+i·∞	-∞+i·QNAN	QNAN+i·QNAN	0+i·QNAN	+0+i·QNAN	QNAN+i·QNAN	-∞+i·QNAN	QNAN+i·QNAN
+i·Y	-∞·Cos(Y)+ i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	-∞+i·0		-0+i·0	+0+i·0		+∞+i·0	QNAN+i·0
-i·0	-∞-i·0		-0-i·0	+0-i·0		+∞-i·0	QNAN-i·0
-i·Y	-∞·Cos(Y)+ i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	-∞+i·QNAN	QNAN+i·QNAN	0+i·QNAN	+0+i·QNAN	QNAN+i·QNAN	-∞+i·QNAN	QNAN+i·QNAN
+i·NAN	-∞+i·QNAN	QNAN+i·QNAN	0+i·QNAN	+0+i·QNAN	QNAN+i·QNAN	-∞+i·QNAN	QNAN+i·QNAN

Notes:

- **The complex sinh(a) function sets the VM status code to** `oneapi::mkl::vm::status::overflow` in the case of overflow, that is, when RE(a), IM(a) are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\sinh(\text{CONJ}(a)) = \text{CONJ}(\sinh(a))$
- $\sinh(-a) = -\sinh(a)$.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

sinpi

Computes the sine of vector elements multiplied by π .

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event sinpi(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event sinpi(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

`sinpi` supports the following precisions.

T
float
double

Description

The `sinpi(a)` function computes the sine of vector elements multiplied by π . For an argument `a`, the function computes $\sin(\pi*a)$.

Argument	Result	Status code
+0	+0	
-0	-0	
+n, positive integer	+0	
-n, negative integer	-0	
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

If arguments $\text{abs}(a_i) \leq 2^{22}$ for single precision or $\text{abs}(a_i) \leq 2^{51}$ for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments which do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See `set_mode` function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the `create_error_handler` function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the `set_mode` function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the *create_error_handler* function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

sqr

Performs element by element squaring of the vector.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event sqr(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event sqr(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

sqr supports the following precisions.

T
float
double

Description

The `sqr()` function performs element by element squaring of the vector.

Argument	Result	Status code
+0	+0	
-0	+0	
$+\infty$	$+\infty$	
$-\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	

The `sqr` function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer `a` containing the input vector of size `n`.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer `a` to the input vector of size `n`.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

sqrt

Computes a square root of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event sqrt(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event sqrt(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

sqrt supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The sqrt function computes a square root of vector elements.

Argument	Result	VM status code
a< +0	QNAN	oneapi::mkl::vm::status::errdom

Parent topic: *VM Mathematical Functions*

sub

Performs element by element subtraction of vector b from vector a.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event sub(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& b,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
.. code-block:: cpp
```

```

namespace oneapi::mkl::vm {
sycl::event sub( sycl::queue& exec_queue, std::int64_t n, const T a, const T *b, T y,
  std::vector<sycl::event> const & depends = {}, oneapi::mkl::vm::mode mode =
  oneapi::mkl::vm::mode::not_defined, oneapi::mkl::vm::error_handler<T> errhandler - {});
} // namespace oneapi::mkl::vm

```

sub supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The sub(a, b) function performs element by element subtraction of vector a and vector b.

Argument 1	Argument 2	Result	Status code
+0	+0	+0	
+0	-0	+0	
-0	+0	+0	
-0	-0	-0	
+∞	+∞	QNAN	
+∞	-∞	+∞	
-∞	+∞	-∞	
-∞	-∞	QNAN	
SNAN	any value	QNAN	
any value	SNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{sub}(x_1+i*y_1, x_2+i*y_2) = (x_1-x_2) + i*(y_1-y_2)$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all RE(x), RE(y), IM(x), IM(y) arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, and sets the VM status code to `oneapi::mkl::vm::status::overflow` (overriding any possible `oneapi::mkl::vm::status::accuracy_warning` status).

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing 1st input vector of size n.

b The buffer b containing 2nd input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the 1st input vector of size n.

b Pointer b to the 2nd input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

tan

Computes tangent of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event tan(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
```

(continues on next page)

(continued from previous page)

```
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event tan(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

tan supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The tan(a) function computes tangent of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 213$ and $\text{abs}(a[i]) \leq 216$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Argument	Result	Status code

-0	-0	
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Tan}(z) = -i * \text{Tanh}(i * z).$$

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

tand

Computes the tangent of vector elements multiplied by $\pi/180$.

Syntax

Buffer API:

```

namespace oneapi::mkl::vm {

sycl::event tand(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

USM API:

```

namespace oneapi::mkl::vm {

sycl::event tand(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

tand supports the following precisions.

T
float
double

Description

The `tand(a)` function computes the tangent of vector elements multiplied by $\pi/180$. For an argument `x`, the function computes $\tan(\pi*x/180)$.

Note that arguments $\text{abs}(a_i) \leq 2^{38}$ for single precision or $\text{abs}(a_i) \leq 2^{67}$ for double precision, they belong to the *fast computational path*: trigonometric function arguments for which VM provides the best possible performance. Avoid arguments which do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer y containing the output vector of size n.

USM API:

y Pointer y to the output vector of size n.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

tanh

Computes hyperbolic tangent of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {

sycl::event tanh(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {

sycl::event tanh(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);

} // namespace oneapi::mkl::vm
```

tanh supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

The $\tanh(a)$ function computes hyperbolic tangent of vector elements.

Argument	Result	Erro Code
+0	+0	
-0	-0	
$+\infty$	+1	
$-\infty$	-1	
QNAN	QNAN	
SNAN	QNAN	

$+i\cdot\infty$	$-1+i\cdot 0$	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	$-1+i\cdot 0$	QNAN+i·QNAN
$+i\cdot Y$	- $1+i\cdot 0\cdot \text{Tan}(Y)$					$+1+i\cdot 0\cdot \text{Tan}(Y)$	QNAN+i·QNAN
$+i\cdot 0$	$-1+i\cdot 0$		$-0+i\cdot 0$	$+0+i\cdot 0$		$+1+i\cdot 0$	QNAN+i·0
$-i\cdot 0$	$-1-i\cdot 0$		$-0-i\cdot 0$	$+0-i\cdot 0$		$+1-i\cdot 0$	QNAN-i·0
$-i\cdot Y$	- $1+i\cdot 0\cdot \text{Tan}(Y)$					$+1+i\cdot 0\cdot \text{Tan}(Y)$	QNAN+i·QNAN
$-i\cdot\infty$	$-1-i\cdot 0$	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	$-1-i\cdot 0$	QNAN+i·QNAN
$+i\cdot \text{NAN}$	$-1+i\cdot 0$	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	$-1+i\cdot 0$	QNAN+i·QNAN

Notes:

- $\tanh(\text{CONJ}(a)) = \text{CONJ}(\tanh(a))$
- $\tanh(-a) = -\tanh(a)$.

The $\tanh(a)$ function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the *set_mode* function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

tanpi

Computes the tangent of vector elements multiplied by π .

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event tanpi(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event tanpi(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
    std::vector<sycl::event> const & depends = {},
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

tanpi supports the following precisions.

T
float
double

Description

The tanpi(a) function computes the tangent of vector elements multiplied by π . For an argument a, the function computes $\tan(\pi*a)$.

Argument	Result	Status code
+0	+0	
-0	+0	
n, even integer	*copysign(0.0, n)	
n, odd integer	*copysign(0.0, -n)	
n + 0.5, for n even integer and n + 0.5 representable	$+\infty$	
n + 0.5, for n odd integer and n + 0.5 representable	$-\infty$	
$+\infty$	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
QNAN	QNAN	
SNAN	QNAN	

The copysign(x, y) function returns the first vector argument x with the sign changed to match that of the second argument y.

If arguments $\text{abs}(a_i) \leq 2^{13}$ for single precision or $\text{abs}(a_i) \leq 2^{67}$ for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments which do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer *y* containing the output vector of size *n*.

USM API:

y Pointer *y* to the output vector of size *n*.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: [VM Mathematical Functions](#)

tgamma

Computes the gamma function of vector elements.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event tgamma(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
    oneapi::mkl::vm::error_handler<T> errhandler = {});
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event tgamma(
    sycl::queue& exec_queue,
    std::int64_t n,
```

(continues on next page)

(continued from previous page)

```

const T *a,
T* y,
std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined,
oneapi::mkl::vm::error_handler<T> errhandler = {});

} // namespace oneapi::mkl::vm

```

tgamma supports the following precisions.

T
float
double

Description

The tgamma(a) function computes the gamma function for elements of the input vector a and writes them to the output vector y. Precision overflow thresholds for the tgamma function are beyond the scope of this document. If the result does not meet the target precision, the function raises sets the VM status code to oneapi::mkl::vm::status::sing.

Argument	Result	Status code
+0	$+\infty$	oneapi::mkl::vm::status::sing
-0	$-\infty$	oneapi::mkl::vm::status::sing
negative integer	QNAN	oneapi::mkl::vm::status::errdom
$-\infty$	QNAN	oneapi::mkl::vm::status::errdom
$+\infty$	$+\infty$	
a > overflow	$+\infty$	oneapi::mkl::vm::status::sing
QNAN	QNAN	
SNAN	QNAN	

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is oneapi::mkl::vm::mode::not_defined.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

errhandler Sets local error handling mode for this function call. See the [create_error_handler](#) function for arguments and their descriptions. This is an optional parameter. The local error handler is disabled by default.

Output Parameters

Buffer API:

y The buffer `y` containing the output vector of size `n`.

USM API:

y Pointer `y` to the output vector of size `n`.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to [Exceptions](#)

Parent topic: [VM Mathematical Functions](#)

trunc

Computes an integer value rounded towards zero for each vector element.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
sycl::event trunc(
    sycl::queue& exec_queue,
    std::int64_t n,
    sycl::buffer<T,1>& a,
    sycl::buffer<T,1>& y,
    oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
sycl::event trunc(
    sycl::queue& exec_queue,
    std::int64_t n,
    const T *a,
    T* y,
```

(continues on next page)

(continued from previous page)

```

std::vector<sycl::event> const & depends = {},
oneapi::mkl::vm::mode mode = oneapi::mkl::vm::mode::not_defined);
} // namespace oneapi::mkl::vm

```

trunc supports the following precisions.

T
float
double

Description

The trunc(a) function computes an integer value rounded towards zero for each vector element.

$$y_i = \begin{cases} \lfloor a_i \rfloor, & a_i \geq 0 \\ \lceil a_i \rceil, & a_i < 0 \end{cases}$$

Argument	Result	Status code
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
QNaN	QNaN	
SNAN	QNaN	

The trunc function does not generate any errors.

Input Parameters

Buffer API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a The buffer a containing input vector of size n.

mode Overrides the global VM mode setting for this function call. See [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

USM API:

exec_queue The queue where the routine should be executed.

n Specifies the number of elements to be calculated.

a Pointer a to the input vector of size n.

depends Vector of dependent events (to wait for input data to be ready).

mode Overrides the global VM mode setting for this function call. See the [set_mode](#) function for possible values and their description. This is an optional parameter. The default value is `oneapi::mkl::vm::mode::not_defined`.

Output Parameters

Buffer API:

y The buffer **y** containing the output vector of size **n**.

USM API:

y Pointer **y** to the output vector of size **n**.

return value (event) Event, signifying availability of computed output and status code(s).

Exceptions

For list of generated exceptions please refer to *Exceptions*

Parent topic: *VM Mathematical Functions*

VM Service Functions

The VM Service functions enable you to set/get the accuracy mode and error code. These functions are available both in the Fortran and C interfaces. The table below lists available VM Service functions and their short description.

Function Short Name	Description
<i>set_mode</i>	Sets the VM mode for given queue
<i>get_mode</i>	Gets the VM mode for given queue
<i>set_status</i>	Sets the VM status code for given queue
<i>get_status</i>	Gets the VM status code for given queue
<i>clear_status</i>	Clears the VM status code for given queue
<i>create_error_handler</i>	Creates the local VM error handler for a function

Parent topic: *Vector Math*

set_mode

Sets a new mode for VM functions according to the mode parameter and returns the previous VM mode.

Syntax

```
namespace oneapi::mkl::vm {
    oneapi::mkl::vm::mode set_mode(
        sycl::queue& exec_queue,
        oneapi::mkl::vm::mode new_mode);
} // namespace oneapi::mkl::vm
```

Description

The `set_mode` function sets a new mode for VM functions according to the `new_mode` parameter and returns the previous VM mode. The mode change has a global effect on all the VM functions within a queue.

The `mode` parameter is designed to control accuracy for a given queue.

Value of mode	Description
Accuracy Control	
<code>oneapi::mkl::vm::mode::ha</code>	High accuracy versions of VM functions.
<code>oneapi::mkl::vm::mode::la</code>	Low accuracy versions of VM functions.
<code>oneapi::mkl::vm::mode::ep</code>	Enhanced performance accuracy versions of VM functions.
<code>oneapi::mkl::vm::mode::not_defined</code>	VM mode not defined. This has no effect.

The assumed value of the `mode` parameter for a new queue, if `set_mode` is not called is `oneapi::mkl::vm::mode::ha`.

Input Parameters

exec_queue The queue where the routine should be executed.

new_mode Specifies the VM mode to be set.

Output Parameters

return value (old_mode) Specifies the former VM mode.

Parent topic: *VM Service Functions*

get_mode

Gets the VM mode.

Syntax

```
namespace oneapi::mkl::vm {
    oneapi::mkl::vm::mode get_mode(
        sycl::queue& exec_queue);
} // namespace oneapi::mkl::vm
```

Description

The function `get_mode` function returns the global VM mode parameter that controls accuracy for a given queue.

Value of mode	Description
Accuracy Control	
<code>oneapi::mkl::vm::mode::high</code>	High accuracy versions of VM functions.
<code>oneapi::mkl::vm::mode::low</code>	Low accuracy versions of VM functions.
<code>oneapi::mkl::vm::mode::enhanced</code>	Enhanced performance accuracy versions of VM functions.
<code>oneapi::mkl::vm::mode::not_defined</code>	VM mode not defined. It means that no special provisions for accuracy have been made for this queue. See set_mode for details.

Input Parameters

exec_queue The queue where the routine should be executed.

Output Parameters

return value The current global VM mode for the queue `exec_queue`.

Parent topic: *VM Service Functions*

set_status

Sets the global VM status according to new value and returns the previous VM status.

Syntax

```
namespace oneapi::mkl::vm {
    oneapi::mkl::vm::status set_status(
        sycl::queue& exec_queue,
        oneapi::mkl::vm::status new_status);
} // namespace oneapi::mkl::vm
```

Description

The `set_status` function sets the global VM status to new value and returns the previous VM status code for a given queue.

The global VM status is a single value and it registers the bitwise-OR of status codes that happened inside VM functions run on the specific queue. For performance reasons, it might be done in non-atomic manner. The possible status codes are listed in the table below.

Status	Description
Successful Execution	
<code>oneapi::mkl::vm::status::success</code>	VM function execution completed successfully
<code>oneapi::mkl::vm::status::not_defined</code>	VM status not defined
Warnings	
<code>oneapi::mkl::vm::status::accuracy_warning</code>	VM function execution completed successfully in a different accuracy mode
Computational status codes	
<code>oneapi::mkl::vm::status::err_domain</code>	Values are out of a range of definition producing invalid (QNaN) result
<code>oneapi::mkl::vm::status::singularity</code>	Values cause divide-by-zero (singularity) computational errors and produce and invalid (QNaN or Inf) result
<code>oneapi::mkl::vm::status::overflow</code>	Flow overflow happened during the calculation process
<code>oneapi::mkl::vm::status::underflow</code>	Flow underflow happened during the calculation process

Input Parameters

exec_queue The queue where the routine should be executed.

new_status Specifies the VM status to be set.

Output Parameters

return value (old_status) Specifies the former VM status.

Parent topic: *VM Service Functions*

get_status

Gets the VM status.

Syntax

```
namespace oneapi::mkl::vm {
    oneapi::mkl::vm::status get_status(
        sycl::queue& exec_queue);
} // namespace oneapi::mkl::vm
```

Description

The `get_status` function gets the VM status for a given queue.

The global VM status is a single value and it registers the bitwise-OR of status codes that happened inside VM functions run on the specific queue. For performance reasons, it might be done in non-atomic manner. The possible status codes are listed in the table below.

Status	Description
Successful Execution	
<code>oneapi::mkl::vm::status::success</code>	VM function execution completed successfully
<code>oneapi::mkl::vm::status::not_defined</code>	VM status not defined
Warnings	
<code>oneapi::mkl::vm::status::accuracy_warning</code>	VM function execution completed successfully in a different accuracy mode
Computational status codes	
<code>oneapi::mkl::vm::status::err_domain</code>	Values are out of a range of definition producing invalid (QNaN) result
<code>oneapi::mkl::vm::status::singularity</code>	Values cause divide-by-zero (singularity) computational errors and produce and invalid (QNaN or Inf) result
<code>oneapi::mkl::vm::status::overflow</code>	Flow overflow happened during the calculation process
<code>oneapi::mkl::vm::status::underflow</code>	Flow underflow happened during the calculation process

Input Parameters

exec_queue The queue where the routine should be executed.

Output Parameters

return value (status) Specifies the VM status.

Parent topic: *VM Service Functions*

clear_status

Resets the global VM status to `oneapi::mkl::vm::status::success` and returns the previous VM status code.

Syntax

```
namespace oneapi::mkl::vm {
    oneapi::mkl::vm::status clear_status(
        sycl::queue& exec_queue);
} // namespace oneapi::mkl::vm
```

Description

The `clear_status` function sets the VM status code to `oneapi::mkl::vm::status::success` and returns the previous VM status code for a given queue.

The global VM status is a single value and it registers the bitwise-OR of status codes that happened inside VM functions run on the specific queue. For performance reasons, it might be done in non-atomic manner. The possible status codes are listed in the table below.

Status code	Description
Successful Execution	
<code>oneapi::mkl::vm::status::success</code>	VM function execution completed successfully
<code>oneapi::mkl::vm::status::not_defined</code>	Status not defined
Warnings	
<code>oneapi::mkl::vm::status::accuracy_warning</code>	VM function execution completed successfully in a different accuracy mode
Computational status codes	
<code>oneapi::mkl::vm::status::errdom</code>	Values are out of a range of definition producing invalid (QNaN) result
<code>oneapi::mkl::vm::status::sing</code>	Values cause divide-by-zero (singularity) computational errors and produce and invalid (QNaN or Inf) result
<code>oneapi::mkl::vm::status::overflow</code>	Flow overflow happened during the calculation process
<code>oneapi::mkl::vm::status::underflow</code>	Flow underflow happened during the calculation process

Input Parameters

exec_queue The queue where the routine should be executed.

Output Parameters

return value (old_status) Specifies the VM status code before the call.

Parent topic: *VM Service Functions*

create_error_handler

Creates an error handler for VM functions that support computational error handling.

Syntax

Buffer API:

```
namespace oneapi::mkl::vm {
oneapi::mkl::vm::error_handler<T> create_error_handler(
    sycl::buffer<oneapi::mkl::vm::status, 1> & status_array,
    int64_t length = 1,
    oneapi::mkl::vm::status status = oneapi::mkl::vm::status::not_defined,
    T fixup = {},
    bool copysign = false);
} // namespace oneapi::mkl::vm
```

USM API:

```
namespace oneapi::mkl::vm {
oneapi::mkl::vm::error_handler<T> create_error_handler(
    oneapi::mkl::vm::status* status_array,
    int64_t length = 1,
    oneapi::mkl::vm::status status = oneapi::mkl::vm::status::not_defined,
```

(continues on next page)

(continued from previous page)

```

T fixup = {},
bool copysign = false);
} // namespace oneapi::mkl::vm

```

`create_error_handler` supports the following precisions.

T
float
double
std::complex<float>
std::complex<double>

Description

`create_error_handler` creates an computational error handler to be passed to VM functions that support computational error handling.

A VM computational error handler supports three modes:

- **Single status mode:** all computational errors that happened during the execution of a function are being written into one single status variable.

After the execution, the single value is either un-changed if no errors happened or contains bitwise-OR of initial value and non-success status codes occurred during computation.

To enable this mode, `status_array` must point to any status-type array or buffer of 1 or more elements and `length` must be 1.

- **Multiple status mode:** each non-successful status code is saved in `status_array` at the same index as the argument causing the non-success status code.

Success status codes are not written to `status_array`. This means the array needs to be allocated and initialized before function execution.

To enable this mode, `status_array` must have at least the same length as the argument and result vectors, and `length` must be set to this length.

- **Fixup mode:** for all arguments that caused a specific error status, results are overwritten by a user-defined value.

To enable this mode, the target `status` and `fixup` values must be set. The `fixup` value is written to results for each argument for which calculation resulted in the `status` status code.

To fix multiple error status codes, `status` can be provided with bitwise-OR of status codes.

If `copysign` is set to true then the sign of `fixup` is set to the same sign as the argument that caused the status code – a suitable option for symmetric math functions.

The following table lists the possible computational status code values.

Status code	Description
Successful Execution	
<code>oneapi::mkl::vm::status::success</code>	VM function execution completed successfully
<code>oneapi::mkl::vm::status::not_defined</code>	Status not defined
Warnings	
<code>oneapi::mkl::vm::status::accuracy_fixup</code>	VM function execution completed successfully in a different accuracy mode
Computational Errors	
<code>oneapi::mkl::vm::status::errdom</code>	Values are out of a range of definition producing invalid (QNaN) result
<code>oneapi::mkl::vm::status::sing</code>	Values cause divide-by-zero (singularity) computational errors and produce and invalid (QNaN or Inf) result
<code>oneapi::mkl::vm::status::overflow</code>	Flow overflow happened during the calculation process
<code>oneapi::mkl::vm::status::underflow</code>	Flow underflow happened during the calculation process

Notes:

- `status_array` must be allocated and initialized before calling VM functions in multiple status error handling mode.
The array should be large enough to contain `n` status codes, where `n` is the same as the input/output vector size for the VM function.
- If no arguments are passed to `create_error_handler`, then an empty object is created with all three error handling modes disabled.
In this case, the VM math functions set the global status code only.

Input Parameters

status_array Array to store status codes (should be a buffer for buffer API).

length Length of the errarray. This is an optional argument, default value is 1.

status_code Status code to match and fix the results. This is an optional argument, default value is `oneapi::mkl::vm::status::not_defined`.

fixup Fixup value for results. This is an optional argument, default value is `0.0`.

copysign Flag for setting the fixup value's sign the same as the argument's. This is an optional argument, default value `false`.

Output Parameters

return value Specifies the error handler object to be created.

Parent topic: *VM Service Functions*

Exceptions

All VM mathematical functions throw exceptions in exceptional cases. The following table summarizes the conditions.

exception	when thrown
oneapi::mkl::invalid_argument	buffer API: $n < 0$; y.get_count() < n; z.get_count() < n; // for sincos
	USM API: $n < 0$; any pointer argument is nullptr

11.3 oneMKL Appendix

11.3.1 Future considerations

The following items are being considered for future versions of this specification:

- Encapsulation of matrix and vector information in classes. Matrix storage information could also be encapsulated.
- More human-readable names for linear algebra functionality, aligned with the P1673 C++ proposal.
- Broader support for row major layout.
- Alternative handling of computational failures.

11.3.2 Acknowledgment

The oneMKL [Technical Advisory Board](#) members provided valuable feedback to the specification and are thanked for their contributions.

RAY TRACING

12.1 Overview

Ray Tracing defines a set of ray tracing and high-fidelity rendering and computation routines for use in a wide variety of 3D graphics uses including, film and television photorealistic visual effects and animation rendering, scientific visualization, high-performance computing computations, gaming, and more. Ray Tracing is designed to allow cooperative execution on a wide variety of computational devices: CPUs, GPUs, FPGAs, and other accelerators, termed “XPU” computation. The functionality is subdivided into several domains: geometric ray tracing computations, volumetric computation and rendering, path guided ray tracing, image denoising, and an integrated rendering infrastructure and API utilizing all the individual kernel capabilities integrated into a highly capable, easy to use rendering engine.

The individual components and their APIs are described. Other design considerations and related components that are not necessarily part of the Ray Tracing specification but that are worth mentioning will be discussed in the appendix.

12.1.1 Component Libraries

There are 4 domains.

- *Embree*: Geometric Ray Tracing Kernel API
- *Open VKL*: Volumetric Ray Tracing Kernel API
- *Open Image Denoise*: High-Fidelity [AI] Image Denoising API
- *OSPRay*: Middleware Scalable Ray Tracing and Rendering API

Embree

Embree is a collection of high-performance ray tracing kernels. The Embree target users are graphics application engineers who want to improve the performance of their photo-realistic rendering application by leveraging Embree’s performance-optimized ray tracing kernels. Embree supports runtime code selection to choose the traversal and build algorithms that best matches the instruction set of your CPU.

Embree supports applications written with the Intel® SPMD Program Compiler (ISPC, <https://ispc.github.io/>) by also providing an ISPC interface to the core ray tracing algorithms. This makes it possible to write a renderer in ISPC that automatically vectorizes and leverages SSE, AVX, AVX2, and AVX-512 instructions. ISPC also supports runtime code selection, thus ISPC will select the best code path for your application.

Embree contains algorithms optimized for incoherent workloads (e.g. Monte Carlo ray tracing algorithms) and coherent workloads (e.g. primary visibility and hard shadow rays).

The single-ray traversal kernels of Embree provide high performance for incoherent workloads and are very easy to integrate into existing rendering applications. Using the stream kernels, even higher performance for incoherent rays

is possible, but integration might require significant code changes to the application to use the stream paradigm. In general for coherent workloads, the stream mode with coherent flag set gives the best performance.

Embree also supports dynamic scenes by implementing high-performance two-level spatial index structure construction algorithms.

Introduction

The Embree API is a low-level C99 ray tracing API which can be used to construct 3D scenes and perform ray queries of different types inside these scenes. All API calls carry the prefix `rtc` (or `RTC` for types) which stands for **ray tracing core**.

The API also exists in an ISPC version, which is almost identical but contains additional functions that operate on ray packets with a size of the native SIMD width used by ISPC. For simplicity this document refers to the C99 version of the API functions. For changes when upgrading from the Embree 2 to the current Embree 3 API see Section [Upgrading from Embree 2 to Embree 3].

The API supports scenes consisting of different geometry types such as triangle meshes, quad meshes (triangle pairs), grid meshes, flat curves, round curves, oriented curves, subdivision meshes, instances, and user-defined geometries. See Section *Scene Object* for more information.

Finding the closest hit of a ray segment with the scene (`rtcIntersect`-type functions), and determining whether any hit between a ray segment and the scene exists (`rtcOccluded`-type functions) are both supported. The API supports queries for single rays, ray packets, and ray streams. See Section *Ray Queries* for more information.

The API is designed in an object-oriented manner, e.g. it contains device objects (`RTCDevice` type), scene objects (`RTCScene` type), geometry objects (`RTCGeometry` type), buffer objects (`RTCBuffer` type), and BVH objects (`RTCBVH` type). All objects are reference counted, and handles can be released by calling the appropriate release function (e.g. `rtcReleaseDevice`) or retained by incrementing the reference count (e.g. `rtcRetainDevice`). In general, API calls that access the same object are not thread-safe, unless specified differently. However, attaching geometries to the same scene and performing ray queries in a scene is thread-safe.

Device Object

Embree supports a device concept, which allows different components of the application to use the Embree API without interfering with each other. An application typically first creates a device using the `rtcNewDevice` function. This device can then be used to construct further objects, such as scenes and geometries. Before the application exits, it should release all devices by invoking `rtcReleaseDevice`. An application typically creates only a single device. If required differently, it should only use a small number of devices at any given time.

Each user thread has its own error flag per device. If an error occurs when invoking an API function, this flag is set to an error code (if it isn't already set by a previous error). See Section `rtcGetDeviceError` for information on how to read the error code and Section `rtcSetDeviceErrorFunction` on how to register a callback that is invoked for each error encountered. It is recommended to always set a error callback function, to detect all errors.

Scene Object

A scene is a container for a set of geometries, and contains a spatial acceleration structure which can be used to perform different types of ray queries.

A scene is created using the `rtcNewScene` function call, and released using the `rtcReleaseScene` function call. To populate a scene with geometries use the `rtcAttachGeometry` call, and to detach them use the `rtcDetachGeometry` call. Once all scene geometries are attached, an `rtcCommitScene` call (or `rtcJoinCommitScene` call) will finish the scene description and trigger building of internal data structures. After the scene got committed, it is safe to perform ray queries (see Section *Ray Queries*) or to query the scene bounding box (see *rtcGetSceneBounds* and *rtcGetSceneLinearBounds*).

If scene geometries get modified or attached or detached, the `rtcCommitScene` call must be invoked before performing any further ray queries for the scene; otherwise the effect of the ray query is undefined. The modification of a geometry, committing the scene, and tracing of rays must always happen sequentially, and never at the same time. Any API call that sets a property of the scene or geometries contained in the scene count as scene modification, e.g. including setting of intersection filter functions.

Scene flags can be used to configure a scene to use less memory (`RTC_SCENE_FLAG_COMPACT`), use more robust traversal algorithms (`RTC_SCENE_FLAG_ROBUST`), and to optimize for dynamic content. See Section *rtcSetSceneFlags* for more details.

A build quality can be specified for a scene to balance between acceleration structure build performance and ray query performance. See Section *rtcSetSceneBuildQuality* for more details on build quality.

Geometry Object

A new geometry is created using the `rtcNewGeometry` function. Depending on the geometry type, different buffers must be bound (e.g. using `rtcSetSharedGeometryBuffer`) to set up the geometry data. In most cases, binding of a vertex and index buffer is required. The number of primitives and vertices of that geometry is typically inferred from the size of these bound buffers.

Changes to the geometry always must be committed using the `rtcCommitGeometry` call before using the geometry. After committing, a geometry is not included in any scene. A geometry can be added to a scene by using the `rtcAttachGeometry` function (to automatically assign a geometry ID) or using the `rtcAttachGeometryById` function (to specify the geometry ID manually). A geometry can get attached to multiple scenes.

All geometry types support multi-segment motion blur with an arbitrary number of equidistant time steps (in the range of 2 to 129) inside a user specified time range. Each geometry can have a different number of time steps and a different time range. The motion blur geometry is defined by linearly interpolating the geometries of neighboring time steps. To construct a motion blur geometry, first the number of time steps of the geometry must be specified using the `rtcSetGeometryTimeStepCount` function, and then a vertex buffer for each time step must be bound, e.g. using the `rtcSetSharedGeometryBuffer` function. Optionally, a time range defining the start (and end time) of the first (and last) time step can be set using the `rtcSetGeometryTimeRange` function. This feature will also allow geometries to appear and disappear during the camera shutter time if the time range is a sub range of $[0,1]$.

The API supports per-geometry filter callback functions (see `rtcSetGeometryIntersectFilterFunction` and `rtcSetGeometryOccludedFilterFunction`) that are invoked for each intersection found during the `rtcIntersect`-type or `rtcOccluded`-type calls. The former ones are called geometry intersection filter functions, the latter ones geometry occlusion filter functions. These filter functions are designed to be used to ignore intersections outside of a user-defined silhouette of a primitive, e.g. to model tree leaves using transparency textures.

Ray Queries

The API supports finding the closest hit of a ray segment with the scene (`rtcIntersect`-type functions), and determining whether any hit between a ray segment and the scene exists (`rtcOccluded`-type functions).

Supported are single ray queries (`rtcIntersect1` and `rtcOccluded1`) as well as ray packet queries for ray packets of size 4 (`rtcIntersect4` and `rtcOccluded4`), ray packets of size 8 (`rtcIntersect8` and `rtcOccluded8`), and ray packets of size 16 (`rtcIntersect16` and `rtcOccluded16`).

Ray streams in a variety of layouts are supported as well, such as streams of single rays (`rtcIntersect1M` and `rtcOccluded1M`), streams of pointers to single rays (`rtcIntersect1p` and `rtcOccluded1p`), streams of ray packets (`rtcIntersectNM` and `rtcOccludedNM`), and large packet-like streams in structure of pointer layout (`rtcIntersectNp` and `rtcOccludedNp`).

See Sections [rtcIntersect1](#) and [rtcOccluded1](#) for a detailed description of how to set up and trace a ray.

See tutorial [Triangle Geometry](#) for a complete example of how to trace single rays and ray packets. Also have a look at the tutorial [Stream Viewer](#) for an example of how to trace ray streams.

Point Queries

The API supports traversal of the BVH using a point query object that specifies a location and a query radius. For all primitives intersecting the according domain, a user defined callback function is called which allows queries such as finding the closest point on the surface geometries of the scene (see Tutorial [Closest Point](#)) or nearest neighbour queries (see Tutorial [Voronoi](#)).

See Section [rtcPointQuery](#) for a detailed description of how to set up point queries.

Collision Detection

The Embree API also supports collision detection queries between two scenes consisting only of user geometries. Embree only performs broadphase collision detection, the narrow phase detection can be performed through a callback function.

See Section [rtcCollide](#) for a detailed description of how to set up collision detection.

See tutorial [Collision Detection](#) for a complete example of collision detection being used on a simple cloth solver.

Miscellaneous

A context filter function, which can be set per ray query is supported (see `rtcInitIntersectContext`). This filter function is designed to change the semantics of the ray query, e.g. to accumulate opacity for transparent shadows, count the number of surfaces along a ray, collect all hits along a ray, etc.

The internal algorithms to build a BVH are exposed through the `RTC BVH` object and `rtcBuildBVH` call. This call makes it possible to build a BVH in a user-specified format over user-specified primitives. See the documentation of the `rtcBuildBVH` call for more details.

For getting the most performance out of Embree, see the Section [\[Performance Recommendations\]](#).

Embree API

rtcNewDevice

NAME

```
rtcNewDevice - creates a new device
```

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCDevice rtcNewDevice(const char* config);
```

DESCRIPTION

This function creates a new device and returns a handle to this device. The device object is reference counted with an initial reference count of 1. The handle can be released using the `rtcReleaseDevice` API call.

The device object acts as a class factory for all other object types. All objects created from the device (like scenes, geometries, etc.) hold a reference to the device, thus the device will not be destroyed unless these objects are destroyed first.

Objects are only compatible if they belong to the same device, e.g it is not allowed to create a geometry in one device and attach it to a scene created with a different device.

A configuration string (`config` argument) can be passed to the device construction. This configuration string can be `NULL` to use the default configuration.

The following configuration is supported:

- `threads=[int]`: Specifies a number of build threads to use. A value of 0 enables all detected hardware threads. By default all hardware threads are used.
- `user_threads=[int]`: Sets the number of user threads that can be used to join and participate in a scene commit using `rtcJoinCommitScene`. The tasking system will only use `threads-user_threads` many worker threads, thus if the app wants to solely use its threads to commit scenes, just set `threads` equal to `user_threads`. This option only has effect with the Intel(R) Threading Building Blocks (TBB) tasking system.
- `set_affinity=[0/1]`: When enabled, build threads are affinity to hardware threads. This option is disabled by default on standard CPUs, and enabled by default on Xeon Phi Processors.
- `start_threads=[0/1]`: When enabled, the build threads are started upfront. This can be useful for benchmarking to exclude thread creation time. This option is disabled by default.
- `isa=[sse2, sse4.2, avx, avx2, avx512]`: Use specified ISA. By default the ISA is selected automatically.
- `max_isa=[sse2, sse4.2, avx, avx2, avx512]`: Configures the automated ISA selection to use maximally the specified ISA.
- `hugepages=[0/1]`: Enables or disables usage of huge pages. Under Linux huge pages are used by default but under Windows and macOS they are disabled by default.
- `enable_selockmemoryprivilege=[0/1]`: When set to 1, this enables the `SeLockMemoryPrivilege` privilege with is required to use huge pages on Windows. This option has an effect only under Windows and is ignored on other platforms. See Section [Huge Page Support] for more details.

- `verbose=[0, 1, 2, 3]`: Sets the verbosity of the output. When set to 0, no output is printed by Embree, when set to a higher level more output is printed. By default Embree does not print anything on the console.
- `frequency_level=[simd128, simd256, simd512]`: Specifies the frequency level the application want to run on, which can be either:
 - a) `simd128` to run at highest frequency
 - b) `simd256` to run at AVX2-heavy frequency level
 - c) `simd512` to run at heavy AVX512 frequency level. When some frequency level is specified, Embree will avoid doing optimizations that may reduce the frequency level below the level specified. E.g. if your app does not use AVX instructions setting “`frequency_level=simd128`” will cause some CPUs to run at highest frequency, which may result in higher application performance if you do much shading. If you application heavily uses AVX code, you should best set the frequency level to `simd256`. Per default Embree tries to avoid reducing the frequency of the CPU by setting the `simd256` level only when the CPU has no significant down clocking.

Different configuration options should be separated by commas, e.g.:

```
rtcNewDevice("threads=1,isa=avx");
```

EXIT STATUS

On success returns a handle of the created device. On failure returns NULL as device and sets a per-thread error code that can be queried using `rtcGetDeviceError(NULL)`.

SEE ALSO

rtcRetainDevice, rtcReleaseDevice

rtcRetainDevice

NAME

```
rtcRetainDevice - increments the device reference count
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcRetainDevice(RTCDevice device);
```

DESCRIPTION

Device objects are reference counted. The `rtcRetainDevice` function increments the reference count of the passed device object (`device` argument). This function together with `rtcReleaseDevice` allows to use the internal reference counting in a C++ wrapper class to manage the ownership of the object.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewDevice, rtcReleaseDevice

rtcReleaseDevice

NAME

```
rtcReleaseDevice - decrements the device reference count
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcReleaseDevice(RTCDevice device);
```

DESCRIPTION

Device objects are reference counted. The `rtcReleaseDevice` function decrements the reference count of the passed device object (`device` argument). When the reference count falls to 0, the device gets destroyed.

All objects created from the device (like scenes, geometries, etc.) hold a reference to the device, thus the device will not get destroyed unless these objects are destroyed first.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewDevice, rtcRetainDevice

rtcGetDeviceProperty

NAME

```
rtcGetDeviceProperty - queries properties of the device
```

SYNOPSIS

```
#include <embree3/rtcore.h>

ssize_t rtcGetDeviceProperty(
    RTCDevice device,
    enum RTCDeviceProperty prop
);
```

DESCRIPTION

The `rtcGetDeviceProperty` function can be used to query properties (`prop` argument) of a device object (`device` argument). The returned property is an integer of type `ssize_t`.

Possible properties to query are:

- `RTC_DEVICE_PROPERTY_VERSION`: Queries the combined version number (MAJOR.MINOR.PATCH) with two decimal digits per component. E.g. for Embree 2.8.3 the integer 208003 is returned.
- `RTC_DEVICE_PROPERTY_VERSION_MAJOR`: Queries the major version number of Embree.
- `RTC_DEVICE_PROPERTY_VERSION_MINOR`: Queries the minor version number of Embree.
- `RTC_DEVICE_PROPERTY_VERSION_PATCH`: Queries the patch version number of Embree.
- `RTC_DEVICE_PROPERTY_NATIVE_RAY4_SUPPORTED`: Queries whether the `rtcIntersect4` and `rtcOccluded4` functions preserve packet size and ray order when invoking callback functions. This is only the case if Embree is compiled with `EMBREE_RAY_PACKETS` and SSE2 (or SSE4.2) enabled, and if the machine it is running on supports SSE2 (or SSE4.2).
- `RTC_DEVICE_PROPERTY_NATIVE_RAY8_SUPPORTED`: Queries whether the `rtcIntersect8` and `rtcOccluded8` functions preserve packet size and ray order when invoking callback functions. This is only the case if Embree is compiled with `EMBREE_RAY_PACKETS` and AVX (or AVX2) enabled, and if the machine it is running on supports AVX (or AVX2).
- `RTC_DEVICE_PROPERTY_NATIVE_RAY16_SUPPORTED`: Queries whether the `rtcIntersect16` and `rtcOccluded16` functions preserve packet size and ray order when invoking callback functions. This is only the case if Embree is compiled with `EMBREE_RAY_PACKETS` and AVX512 enabled, and if the machine it is running on supports AVX512.
- `RTC_DEVICE_PROPERTY_RAY_STREAM_SUPPORTED`: Queries whether `rtcIntersect1M`, `rtcIntersect1Mp`, `rtcIntersectNM`, `rtcIntersectNp`, `rtcOccluded1M`, `rtcOccluded1Mp`, `rtcOccludedNM`, and `rtcOccludedNp` are supported. This is only the case if Embree is compiled with `EMBREE_RAY_PACKETS` enabled.
- `RTC_DEVICE_PROPERTY_RAY_MASK_SUPPORTED`: Queries whether ray masks are supported. This is only the case if Embree is compiled with `EMBREE_RAY_MASK` enabled.

- `RTC_DEVICE_PROPERTY_BACKFACE_CULLING_ENABLED`: Queries whether back face culling is enabled. This is only the case if Embree is compiled with `EMBREE_BACKFACE_CULLING` enabled.
- `RTC_DEVICE_PROPERTY_COMPACT_POLYS_ENABLED`: Queries whether compact polys is enabled. This is only the case if Embree is compiled with `EMBREE_COMPACT_POLYS` enabled.
- `RTC_DEVICE_PROPERTY_FILTER_FUNCTION_SUPPORTED`: Queries whether filter functions are supported, which is the case if Embree is compiled with `EMBREE_FILTER_FUNCTION` enabled.
- `RTC_DEVICE_PROPERTY_IGNORE_INVALID_RAYS_ENABLED`: Queries whether invalid rays are ignored, which is the case if Embree is compiled with `EMBREE_IGNORE_INVALID_RAYS` enabled.
- `RTC_DEVICE_PROPERTY_TRIANGLE_GEOMETRY_SUPPORTED`: Queries whether triangles are supported, which is the case if Embree is compiled with `EMBREE_GEOMETRY_TRIANGLE` enabled.
- `RTC_DEVICE_PROPERTY_QUAD_GEOMETRY_SUPPORTED`: Queries whether quads are supported, which is the case if Embree is compiled with `EMBREE_GEOMETRY_QUAD` enabled.
- `RTC_DEVICE_PROPERTY_SUBDIVISION_GEOMETRY_SUPPORTED`: Queries whether subdivision meshes are supported, which is the case if Embree is compiled with `EMBREE_GEOMETRY_SUBDIVISION` enabled.
- `RTC_DEVICE_PROPERTY_CURVE_GEOMETRY_SUPPORTED`: Queries whether curves are supported, which is the case if Embree is compiled with `EMBREE_GEOMETRY_CURVE` enabled.
- `RTC_DEVICE_PROPERTY_POINT_GEOMETRY_SUPPORTED`: Queries whether points are supported, which is the case if Embree is compiled with `EMBREE_GEOMETRY_POINT` enabled.
- `RTC_DEVICE_PROPERTY_USER_GEOMETRY_SUPPORTED`: Queries whether user geometries are supported, which is the case if Embree is compiled with `EMBREE_GEOMETRY_USER` enabled.
- `RTC_DEVICE_PROPERTY_TASKING_SYSTEM`: Queries the tasking system Embree is compiled with. Possible return values are:
 0. internal tasking system
 1. Intel Threading Building Blocks (TBB)
 2. Parallel Patterns Library (PPL)
- `RTC_DEVICE_PROPERTY_JOIN_COMMIT_SUPPORTED`: Queries whether `rtcJoinCommitScene` is supported. This is not the case when Embree is compiled with PPL or older versions of TBB.
- `RTC_DEVICE_PROPERTY_PARALLEL_COMMIT_SUPPORTED`: Queries whether `rtcCommitScene` can get invoked from multiple TBB worker threads concurrently. This feature is only supported starting with TBB 2019 Update 9.

EXIT STATUS

On success returns the value of the queried property. For properties returning a boolean value, the return value 0 denotes `false` and 1 denotes `true`.

On failure zero is returned and an error code is set that can be queried using `rtcGetDeviceError`.

rtcGetDeviceError

NAME

```
rtcGetDeviceError - returns the error code of the device
```

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCError rtcGetDeviceError(RTCDevice device);
```

DESCRIPTION

Each thread has its own error code per device. If an error occurs when calling an API function, this error code is set to the occurred error if it stores no previous error. The `rtcGetDeviceError` function reads and returns the currently stored error and clears the error code. This assures that the returned error code is always the first error occurred since the last invocation of `rtcGetDeviceError`.

Possible error codes returned by `rtcGetDeviceError` are:

- `RTC_ERROR_NONE`: No error occurred.
- `RTC_ERROR_UNKNOWN`: An unknown error has occurred.
- `RTC_ERROR_INVALID_ARGUMENT`: An invalid argument was specified.
- `RTC_ERROR_INVALID_OPERATION`: The operation is not allowed for the specified object.
- `RTC_ERROR_OUT_OF_MEMORY`: There is not enough memory left to complete the operation.
- `RTC_ERROR_UNSUPPORTED_CPU`: The CPU is not supported as it does not support the lowest ISA Embree is compiled for.
- `RTC_ERROR_CANCELLED`: The operation got canceled by a memory monitor callback or progress monitor callback function.

When the device construction fails, `rtcNewDevice` returns `NULL` as device. To detect the error code of a such a failed device construction, pass `NULL` as device to the `rtcGetDeviceError` function. For all other invocations of `rtcGetDeviceError`, a proper device pointer must be specified.

EXIT STATUS

Returns the error code for the device.

SEE ALSO

rtcSetDeviceErrorFunction

rtcSetDeviceErrorFunction

NAME

`rtcSetDeviceErrorFunction` - sets an error callback function for the device

SYNOPSIS

```
#include <embree3/rtcore.h>

typedef void (*RTCErrorFunction)(
    void* userPtr,
    RTCError code,
    const char* str
);

void rtcSetDeviceErrorFunction(
    RTCDevice device,
    RTCErrorFunction error,
    void* userPtr
);
```

DESCRIPTION

Using the `rtcSetDeviceErrorFunction` call, it is possible to set a callback function (error argument) with payload (userPtr argument), which is called whenever an error occurs for the specified device (device argument).

Only a single callback function can be registered per device, and further invocations overwrite the previously set callback function. Passing NULL as function pointer disables the registered callback function.

When the registered callback function is invoked, it gets passed the user-defined payload (userPtr argument as specified at registration time), the error code (code argument) of the occurred error, as well as a string (str argument) that further describes the error.

The error code is also set if an error callback function is registered.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcGetDeviceError

rtcSetDeviceMemoryMonitorFunction

NAME

```
rtcSetDeviceMemoryMonitorFunction - registers a callback function
to track memory consumption
```

SYNOPSIS

```
#include <embree3/rtcore.h>

typedef bool (*RTCMemoryMonitorFunction)(
    void* userPtr,
    ssize_t bytes,
    bool post
);

void rtcSetDeviceMemoryMonitorFunction(
    RTCDevice device,
    RTCMemoryMonitorFunction memoryMonitor,
    void* userPtr
);
```

DESCRIPTION

Using the `rtcSetDeviceMemoryMonitorFunction` call, it is possible to register a callback function (`memoryMonitor` argument) with payload (`userPtr` argument) for a device (`device` argument), which is called whenever internal memory is allocated or deallocated by objects of that device. Using this memory monitor callback mechanism, the application can track the memory consumption of an Embree device, and optionally terminate API calls that consume too much memory.

Only a single callback function can be registered per device, and further invocations overwrite the previously set callback function. Passing `NULL` as function pointer disables the registered callback function.

Once registered, the Embree device will invoke the memory monitor callback function before or after it allocates or frees important memory blocks. The callback function gets passed the payload as specified at registration time (`userPtr` argument), the number of bytes allocated or deallocated (`bytes` argument), and whether the callback is invoked after the allocation or deallocation took place (`post` argument). The callback function might get called from multiple threads concurrently.

The application can track the current memory usage of the Embree device by atomically accumulating the `bytes` input parameter provided to the callback function. This parameter will be `>0` for allocations and `<0` for deallocations.

Embree will continue its operation normally when returning `true` from the callback function. If `false` is returned, Embree will cancel the current operation with the `RTC_ERROR_OUT_OF_MEMORY` error code. Issuing multiple cancel requests from different threads is allowed. Canceling will only happen when the callback was called for allocations (`bytes > 0`), otherwise the cancel request will be ignored.

If a callback to cancel was invoked before the allocation happens (`post == false`), then the `bytes` parameter should not be accumulated, as the allocation will never happen. If the callback to cancel was invoked after the allocation happened (`post == true`), then the `bytes` parameter should be accumulated, as the allocation properly happened and a deallocation will later free that data block.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewDevice

rtcNewScene

NAME

```
rtcNewScene - creates a new scene
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
RTCScene rtcNewScene(RTCDevice device);
```

DESCRIPTION

This function creates a new scene bound to the specified device (device argument), and returns a handle to this scene. The scene object is reference counted with an initial reference count of 1. The scene handle can be released using the `rtcReleaseScene` API call.

EXIT STATUS

On success a scene handle is returned. On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcRetainScene, rtcReleaseScene

rtcGetSceneDevice

NAME

rtcGetSceneDevice - returns the device the scene got created in

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
RTCDevice rtcGetSceneDevice(RTCScene scene);
```

DESCRIPTION

This function returns the device object the scene got created in. The returned handle own one additional reference to the device object, thus you should need to call `rtcReleaseDevice` when the returned handle is no longer required.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcReleaseDevice

rtcRetainScene

NAME

rtcRetainScene - increments the scene reference count

SYNOPSIS

```
#include <embree3/rtcore.h>
void rtcRetainScene(RTCScene scene);
```

DESCRIPTION

Scene objects are reference counted. The `rtcRetainScene` function increments the reference count of the passed scene object (`scene` argument). This function together with `rtcReleaseScene` allows to use the internal reference counting in a C++ wrapper class to handle the ownership of the object.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewScene, rtcReleaseScene

rtcReleaseScene

NAME

```
rtcReleaseScene - decrements the scene reference count
```

SYNOPSIS

```
#include <embree3/rtcore.h>
void rtcReleaseScene(RTCScene scene);
```

DESCRIPTION

Scene objects are reference counted. The `rtcReleaseScene` function decrements the reference count of the passed scene object (`scene` argument). When the reference count falls to 0, the scene gets destroyed.

The scene holds a reference to all attached geometries, thus if the scene gets destroyed, all geometries get detached and their reference count decremented.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewScene, *rtcRetainScene*

rtcAttachGeometry

NAME

rtcAttachGeometry - attaches a geometry to the scene

SYNOPSIS

```
#include <embree3/rtcore.h>

unsigned int rtcAttachGeometry(
    RTCScene scene,
    RTCGeometry geometry
);
```

DESCRIPTION

The `rtcAttachGeometry` function attaches a geometry (`geometry` argument) to a scene (`scene` argument) and assigns a geometry ID to that geometry. All geometries attached to a scene are defined to be included inside the scene. A geometry can get attached to multiple scene. The geometry ID is unique for the scene, and is used to identify the geometry when hit by a ray during ray queries.

This function is thread-safe, thus multiple threads can attach geometries to a scene in parallel.

The geometry IDs are assigned sequentially, starting from 0, as long as no geometry got detached. If geometries got detached, the implementation will reuse IDs in an implementation dependent way. Consequently sequential assignment is no longer guaranteed, but a compact range of IDs.

These rules allow the application to manage a dynamic array to efficiently map from geometry IDs to its own geometry representation. Alternatively, the application can also use per-geometry user data to map to its geometry representation. See `rtcSetGeometryUserData` and `rtcGetGeometryUserData` for more information.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcAttachGeometryByID

NAME

```
rtcAttachGeometryByID - attaches a geometry to the scene
    using a specified geometry ID
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcAttachGeometryByID(
    RTCScene scene,
    RTCGeometry geometry,
    unsigned int geomID
);
```

DESCRIPTION

The `rtcAttachGeometryByID` function attaches a geometry (`geometry` argument) to a scene (`scene` argument) and assigns a user provided geometry ID (`geomID` argument) to that geometry. All geometries attached to a scene are defined to be included inside the scene. A geometry can get attached to multiple scenes. The passed user-defined geometry ID is used to identify the geometry when hit by a ray during ray queries. Using this function, it is possible to share the same IDs to refer to geometries inside the application and Embree.

This function is thread-safe, thus multiple threads can attach geometries to a scene in parallel.

The user-provided geometry ID must be unused in the scene, otherwise the creation of the geometry will fail. Further, the user-provided geometry IDs should be compact, as Embree internally creates a vector which size is equal to the largest geometry ID used. Creating very large geometry IDs for small scenes would thus cause a memory consumption and performance overhead.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcAttachGeometry

rtcDetachGeometry

NAME

rtcDetachGeometry - detaches a geometry from the scene

SYNOPSIS

```
#include <embree3/rtcore.h>
void rtcDetachGeometry(RTCScene scene, unsigned int geomID);
```

DESCRIPTION

This function detaches a geometry identified by its geometry ID (`geomID` argument) from a scene (`scene` argument). When detached, the geometry is no longer contained in the scene.

This function is thread-safe, thus multiple threads can detach geometries from a scene at the same time.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcGetGeometry

NAME

```
rtcGetGeometry - returns the geometry bound to  
the specified geometry ID
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
RTCGeometry rtcGetGeometry(RTCScene scene, unsigned int geomID);
```

DESCRIPTION

The `rtcGetGeometry` function returns the geometry that is bound to the specified geometry ID (`geomID` argument) for the specified scene (`scene` argument). This function just looks up the handle and does *not* increment the reference count. If you want to get ownership of the handle, you need to additionally call `rtcRetainGeometry`.

This function is not thread safe and thus can be used during rendering. However, it is generally recommended to store the geometry handle inside the application's geometry representation and look up the geometry handle from that representation directly.

If you need a thread safe version of this function please use *rtcGetGeometryThreadSafe*.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcAttachGeometry, *rtcAttachGeometryByID*, *rtcGetGeometryThreadSafe*

rtcGetGeometryThreadSafe

NAME

```
rtcGetGeometryThreadSafe - returns the geometry bound to  
the specified geometry ID
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
RTCGeometry rtcGetGeometryThreadSafe(RTCScene scene, unsigned int geomID);
```

DESCRIPTION

The `rtcGetGeometryThreadSafe` function returns the geometry that is bound to the specified geometry ID (`geomID` argument) for the specified scene (`scene` argument). This function just looks up the handle and does *not* increment the reference count. If you want to get ownership of the handle, you need to additionally call `rtcRetainGeometry`.

This function is thread safe and should NOT get used during rendering. If you need a fast non-thread safe version during rendering please use the *rtcGetGeometry* function.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

rtcCommitScene

NAME

```
rtcCommitScene - commits scene changes
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcCommitScene(RTCScene scene);
```

DESCRIPTION

The `rtcCommitScene` function commits all changes for the specified scene (`scene` argument). This internally triggers building of a spatial acceleration structure for the scene using all available worker threads. Ray queries can be performed only after committing all scene changes.

If the application uses TBB 2019 Update 9 or later for parallelization of rendering, lazy scene construction during rendering is supported by `rtcCommitScene`. Therefore `rtcCommitScene` can get called from multiple TBB worker threads concurrently for the same scene. The `rtcCommitScene` function will then internally isolate the scene construction using a `tbb::isolated_task_group`. The alternative approach of using `rtcJoinCommitScene` which uses an `tbb::task_arena` internally, is not recommended due to its high runtime overhead.

If scene geometries get modified or attached or detached, the `rtcCommitScene` call must be invoked before performing any further ray queries for the scene; otherwise the effect of the ray query is undefined. The modification of a geometry, committing the scene, and tracing of rays must always happen sequentially, and never at the same time. Any API call that sets a property of the scene or geometries contained in the scene count as scene modification, e.g. including setting of intersection filter functions.

The kind of acceleration structure built can be influenced using scene flags (see `rtcSetSceneFlags`), and the quality can be specified using the `rtcSetSceneBuildQuality` function.

Embree silently ignores primitives during spatial acceleration structure construction that would cause numerical issues, e.g. primitives containing NaNs, INFs, or values greater than `1.844E18f` (as no reasonable calculations can be performed with such values without causing overflows).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcJoinCommitScene

rtcJoinCommitScene

NAME

```
rtcJoinCommitScene - commits the scene from multiple threads
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcJoinCommitScene(RTCScene scene);
```

DESCRIPTION

The `rtcJoinCommitScene` function commits all changes for the specified scene (`scene` argument). The scene commit internally triggers building of a spatial acceleration structure for the scene. Ray queries can be performed after scene changes got properly committed.

The `rtcJoinCommitScene` function can get called from multiple user threads which will all cooperate in the build operation. All threads calling into this function will return from `rtcJoinCommitScene` after the scene commit is finished. All threads must consistently call `rtcJoinCommitScene` and not `rtcCommitScene`.

In contrast to the `rtcCommitScene` function, the `rtcJoinCommitScene` function can be called from multiple user threads, while the `rtcCommitScene` can only get called from multiple TBB worker threads when used concurrently. For optimal performance we strongly recommend using TBB inside the application together with the `rtcCommitScene` function and to avoid using the `rtcJoinCommitScene` function.

The `rtcJoinCommitScene` feature allows a flexible way to lazily create hierarchies during rendering. A thread reaching a not-yet-constructed sub-scene of a two-level scene can generate the sub-scene geometry and call `rtcJoinCommitScene` on that just generated scene. During construction, further threads reaching the not-yet-built scene can join the build operation by also invoking `rtcJoinCommitScene`. A thread that calls `rtcJoinCommitScene` after the build finishes will directly return from the `rtcJoinCommitScene` call.

Multiple scene commit operations on different scenes can be running at the same time, hence it is possible to commit many small scenes in parallel, distributing the commits to many threads.

When using Embree with the Intel® Threading Building Blocks (which is the default), threads that call `rtcJoinCommitScene` will join the build operation, but other TBB worker threads might also participate in the build. To avoid thread oversubscription, we recommend using TBB also inside the application. Further, the join mode only works properly starting with TBB v4.4 Update 1. For earlier TBB versions, threads that call `rtcJoinCommitScene` to join a running build will just trigger the build and wait for the build to finish. Further, old TBB versions with `TBB_INTERFACE_VERSION_MAJOR < 8` do not support `rtcJoinCommitScene`, and invoking this function will result in an error.

When using Embree with the internal tasking system, only threads that call `rtcJoinCommitScene` will perform the build operation, and no additional worker threads will be scheduled.

When using Embree with the Parallel Patterns Library (PPL), `rtcJoinCommitScene` is not supported and calling that function will result in an error.

To detect whether `rtcJoinCommitScene` is supported, use the `rtcGetDeviceProperty` function.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetSceneProgressMonitorFunction

NAME

```
rtcSetSceneProgressMonitorFunction - registers a callback
to track build progress
```

SYNOPSIS

```
#include <embree3/rtcore.h>

typedef bool (*RTCProgressMonitorFunction)(
    void* ptr,
    double n
);

void rtcSetSceneProgressMonitorFunction(
    RTCScene scene,
    RTCProgressMonitorFunction progress,
    void* userPtr
);
```

DESCRIPTION

Embree supports a progress monitor callback mechanism that can be used to report progress of hierarchy build operations and to cancel build operations.

The `rtcSetSceneProgressMonitorFunction` registers a progress monitor callback function (`progress` argument) with payload (`userPtr` argument) for the specified scene (`scene` argument).

Only a single callback function can be registered per scene, and further invocations overwrite the previously set callback function. Passing `NULL` as function pointer disables the registered callback function.

Once registered, Embree will invoke the callback function multiple times during hierarchy build operations of the scene, by passing the payload as set at registration time (`userPtr` argument), and a double in the range `[0, 1]` which estimates the progress of the operation (`n` argument). The callback function might be called from multiple threads concurrently.

When returning `true` from the callback function, Embree will continue the build operation normally. When returning `false`, Embree will cancel the build operation with the `RTC_ERROR_CANCELLED` error code. Issuing multiple cancel requests for the same build operation is allowed.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetSceneBuildQuality

NAME

```
rtcSetSceneBuildQuality - sets the build quality for
the scene
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetSceneBuildQuality(
    RTCScene scene,
    enum RTCBuildQuality quality
);
```

DESCRIPTION

The `rtcSetSceneBuildQuality` function sets the build quality (quality argument) for the specified scene (scene argument). Possible values for the build quality are:

- `RTC_BUILD_QUALITY_LOW`: Create lower quality data structures, e.g. for dynamic scenes. A two-level spatial index structure is built when enabling this mode, which supports fast partial scene updates, and allows for setting a per-geometry build quality through the `rtcSetGeometryBuildQuality` function.
- `RTC_BUILD_QUALITY_MEDIUM`: Default build quality for most usages. Gives a good compromise between build and render performance.
- `RTC_BUILD_QUALITY_HIGH`: Create higher quality data structures for final-frame rendering. For certain geometry types this enables a spatial split BVH.

Selecting a higher build quality results in better rendering performance but slower scene commit times. The default build quality for a scene is `RTC_BUILD_QUALITY_MEDIUM`.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcSetGeometryBuildQuality

rtcSetSceneFlags

NAME

```
rtcSetSceneFlags - sets the flags for the scene
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetSceneFlags(RTCScene scene, enum RTCSceneFlags flags);
```

DESCRIPTION

The `rtcSetSceneFlags` function sets the scene flags (`flags` argument) for the specified scene (`scene` argument). Possible scene flags are:

- `RTC_SCENE_FLAG_NONE`: No flags set.
- `RTC_SCENE_FLAG_DYNAMIC`: Provides better build performance for dynamic scenes (but also higher memory consumption).
- `RTC_SCENE_FLAG_COMPACT`: Uses compact acceleration structures and avoids algorithms that consume much memory.
- `RTC_SCENE_FLAG_ROBUST`: Uses acceleration structures that allow for robust traversal, and avoids optimizations that reduce arithmetic accuracy. This mode is typically used for avoiding artifacts caused by rays shooting through edges of neighboring primitives.
- `RTC_SCENE_FLAG_CONTEXT_FILTER_FUNCTION`: Enables support for a filter function inside the intersection context for this scene. See Section *rtcInitIntersectContext* for more details.

Multiple flags can be enabled using an or operation, e.g. `RTC_SCENE_FLAG_COMPACT | RTC_SCENE_FLAG_ROBUST`.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcGetSceneFlags

rtcGetSceneFlags

NAME

rtcGetSceneFlags - returns the flags of the scene

SYNOPSIS

```
#include <embree3/rtcore.h>
enum RTCSceneFlags rtcGetSceneFlags(RTCScene scene);
```

DESCRIPTION

Queries the flags of a scene. This function can be useful when setting individual flags, e.g. to just set the robust mode without changing other flags the following way:

```
RTCSceneFlags flags = rtcGetSceneFlags(scene);
rtcSetSceneFlags(scene, RTC_SCENE_FLAG_ROBUST | flags);
```

EXIT STATUS

On failure `RTC_SCENE_FLAG_NONE` is returned and an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcSetSceneFlags

rtcGetSceneBounds

NAME

rtcGetSceneBounds - returns the axis-aligned bounding box of the scene

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCORE_ALIGN(16) RTCBounds
{
    float lower_x, lower_y, lower_z, align0;
    float upper_x, upper_y, upper_z, align1;
};

void rtcGetSceneBounds(
    RTCScene scene,
    struct RTCBounds* bounds_o
);
```

DESCRIPTION

The `rtcGetSceneBounds` function queries the axis-aligned bounding box of the specified scene (`scene` argument) and stores that bounding box to the provided destination pointer (`bounds_o` argument). The stored bounding box consists of lower and upper bounds for the x, y, and z dimensions as specified by the `RTCBounds` structure.

The provided destination pointer must be aligned to 16 bytes. The function may be invoked only after committing the scene; otherwise the result is undefined.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcGetSceneLinearBounds, rtcCommitScene, rtcJoinCommitScene

rtcGetSceneLinearBounds

NAME

rtcGetSceneLinearBounds - returns the linear bounds of the scene

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCORE_ALIGN(16) RTCLinearBounds
{
    RTCBounds bounds0;
    RTCBounds bounds1;
};

void rtcGetSceneLinearBounds(
    RTCScene scene,
    struct RTCLinearBounds* bounds_o
);
```

DESCRIPTION

The `rtcGetSceneLinearBounds` function queries the linear bounds of the specified scene (`scene` argument) and stores them to the provided destination pointer (`bounds_o` argument). The stored linear bounds consist of bounding boxes for time 0 (`bounds0` member) and time 1 (`bounds1` member) as specified by the `RTCLinearBounds` structure. Linearly interpolating these bounds to a specific time `t` yields bounds for the geometry at that time.

The provided destination pointer must be aligned to 16 bytes. The function may be called only after committing the scene, otherwise the result is undefined.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

    RTC_GEOMETRY_TYPE_ORIENTED_DISC_POINT,
    RTC_GEOMETRY_TYPE_USER,
    RTC_GEOMETRY_TYPE_INSTANCE
};

RTCGeometry rtcNewGeometry(
    RTCDevice device,
    enum RTCGeometryType type
);
```

DESCRIPTION

Geometries are objects that represent an array of primitives of the same type. The `rtcNewGeometry` function creates a new geometry of specified type (`type` argument) bound to the specified device (`device` argument) and returns a handle to this geometry. The geometry object is reference counted with an initial reference count of 1. The geometry handle can be released using the `rtcReleaseGeometry` API call.

Supported geometry types are triangle meshes (`RTC_GEOMETRY_TYPE_TRIANGLE` type), quad meshes (triangle pairs) (`RTC_GEOMETRY_TYPE_QUAD` type), Catmull-Clark subdivision surfaces (`RTC_GEOMETRY_TYPE_SUBDIVISION` type), curve geometries with different bases (`RTC_GEOMETRY_TYPE_FLAT_LINEAR_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_BEZIER_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_BSPLINE_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_HERMITE_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_CATMULL_ROM_CURVE`, `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_BEZIER_CURVE`, `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_BSPLINE_CURVE`, `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_HERMITE_CURVE`, `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_CATMULL_ROM_CURVE`, `RTC_GEOMETRY_TYPE_CONE_LINEAR_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_LINEAR_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_BEZIER_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_BSPLINE_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_HERMITE_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_CATMULL_ROM_CURVE` types) grid meshes (`RTC_GEOMETRY_TYPE_GRID`), point geometries (`RTC_GEOMETRY_TYPE_SPHERE_POINT`, `RTC_GEOMETRY_TYPE_DISC_POINT`, `RTC_TYPE_ORIENTED_DISC_POINT`), user-defined geometries (`RTC_GEOMETRY_TYPE_USER`), and instances (`RTC_GEOMETRY_TYPE_INSTANCE`).

The types `RTC_GEOMETRY_TYPE_ROUND_BEZIER_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_BSPLINE_CURVE`, and `RTC_GEOMETRY_TYPE_ROUND_CATMULL_ROM_CURVE` will treat the curve as a sweep surface of a varying-radius circle swept tangentially along the curve. The types `RTC_GEOMETRY_TYPE_FLAT_BEZIER_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_BSPLINE_CURVE`, and `RTC_GEOMETRY_TYPE_FLAT_CATMULL_ROM_CURVE` use ray-facing ribbons as a faster-to-intersect approximation.

After construction, geometries are enabled by default and not attached to any scene. Geometries can be disabled (`rtcDisableGeometry` call), and enabled again (`rtcEnableGeometry` call). A geometry can be attached to multiple scenes using the `rtcAttachGeometry` call (or `rtcAttachGeometryByID` call), and detached using the `rtcDetachGeometry` call. During attachment, a geometry ID is assigned to the geometry (or assigned by the user when using the `rtcAttachGeometryByID` call), which uniquely identifies the geometry inside that scene. This identifier is returned when primitives of the geometry are hit in later ray queries for the scene.

Geometries can also be modified, including their vertex and index buffers. After modifying a buffer, `rtcUpdateGeometryBuffer` must be called to notify that the buffer got modified.

The application can use the `rtcSetGeometryUserData` function to set a user data pointer to its own geometry representation, and later read out this pointer using the `rtcGetGeometryUserData` function.

After setting up the geometry or modifying it, `rtcCommitGeometry` must be called to finish the geometry setup. After committing the geometry, vertex data interpolation can be performed using the `rtcInterpolate` and `rtcInterpolateN` functions.

A build quality can be specified for a geometry using the `rtcSetGeometryBuildQuality` function, to balance between acceleration structure build performance and ray query performance. The build quality per geometry will be used if a two-level acceleration structure is built internally, which is the case if the `RTC_BUILD_QUALITY_LOW` is set as the scene build quality. See Section [rtcSetSceneBuildQuality](#) for more details.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_TRIANGLE

NAME

```
RTC_GEOMETRY_TYPE_TRIANGLE - triangle geometry type
```

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCGeometry geometry =
    rtcNewGeometry(device, RTC_GEOMETRY_TYPE_TRIANGLE);
```

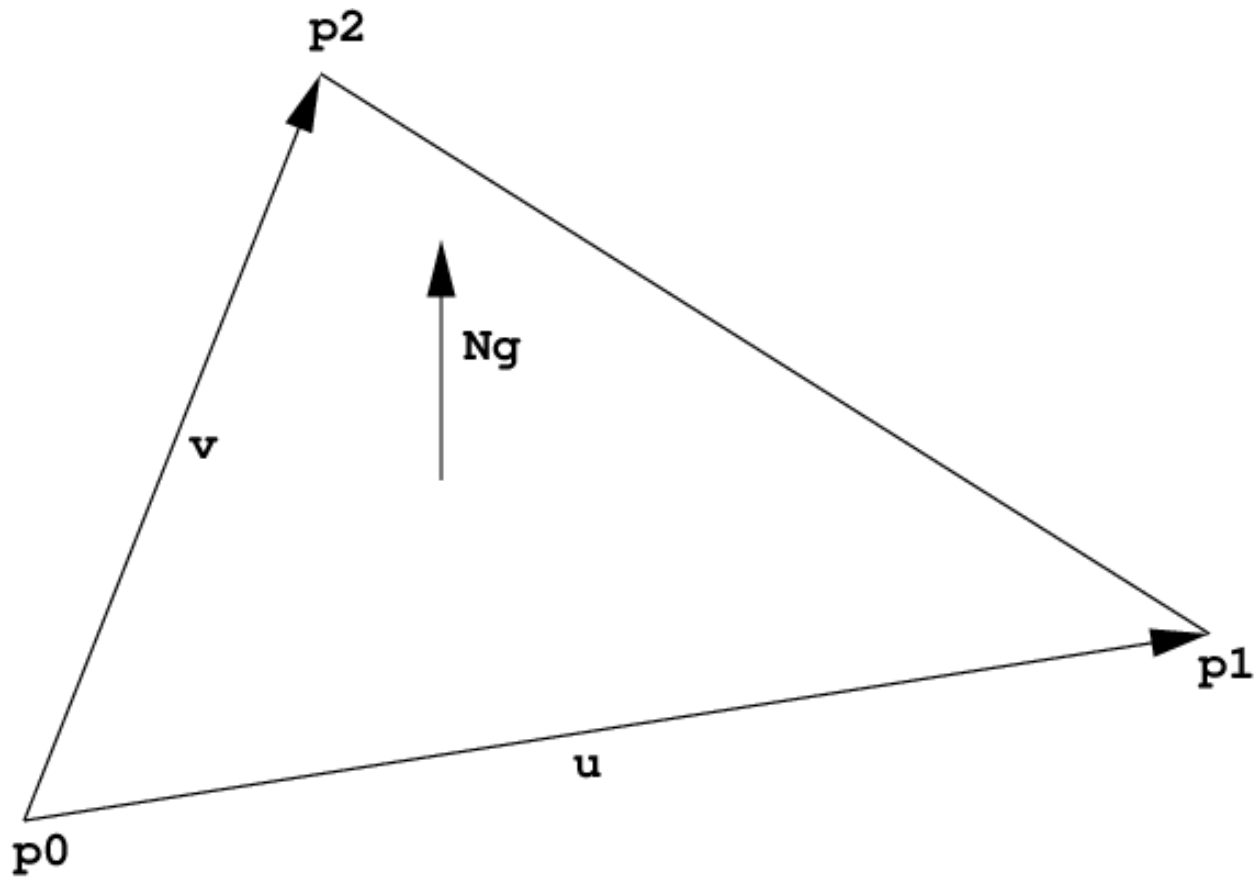

DESCRIPTION

Triangle meshes are created by passing `RTC_GEOMETRY_TYPE_TRIANGLE` to the `rtcNewGeometry` function call. The triangle indices can be specified by setting an index buffer (`RTC_BUFFER_TYPE_INDEX` type) and the triangle vertices by setting a vertex buffer (`RTC_BUFFER_TYPE_VERTEX` type). See `rtcSetGeometryBuffer` and `rtcSetSharedGeometryBuffer` for more details on how to set buffers. The index buffer must contain an array of three 32-bit indices per triangle (`RTC_FORMAT_UINT3` format) and the number of primitives is inferred from the size of that buffer. The vertex buffer must contain an array of single precision x, y, z floating point coordinates (`RTC_FORMAT_FLOAT3` format), and the number of vertices is inferred from the size of that buffer. The vertex buffer can be at most 16 GB large.

The parameterization of a triangle uses the first vertex p_0 as base point, the vector $p_1 - p_0$ as u-direction and the vector $p_2 - p_0$ as v-direction. Thus vertex attributes t_0, t_1, t_2 can be linearly interpolated over the triangle the following way:

$$\begin{aligned} t_{uv} &= (1-u-v)*t_0 + u*t_1 + v*t_2 \\ &= t_0 + u*(t_1-t_0) + v*(t_2-t_0) \end{aligned}$$

A triangle whose vertices are laid out counter-clockwise has its geometry normal pointing upwards outside the front face, like illustrated in the following picture:

For multi-segment motion blur, the number of time steps must be first specified using the `rtcSetGeometryTimeStepCount` call. Then a vertex buffer for each time step can be set using different buffer slots, and all these buffers have to have the same stride and size.

Also see tutorial [Triangle Geometry](#) for an example of how to create triangle meshes.

EXIT STATUS

On failure NULL is returned and an error code is set that be get queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewGeometry

RTC_GEOMETRY_TYPE_QUAD

NAME

RTC_GEOMETRY_TYPE_QUAD - quad geometry type

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCGeometry geometry =
    rtcNewGeometry(device, RTC_GEOMETRY_TYPE_QUAD);
```

DESCRIPTION

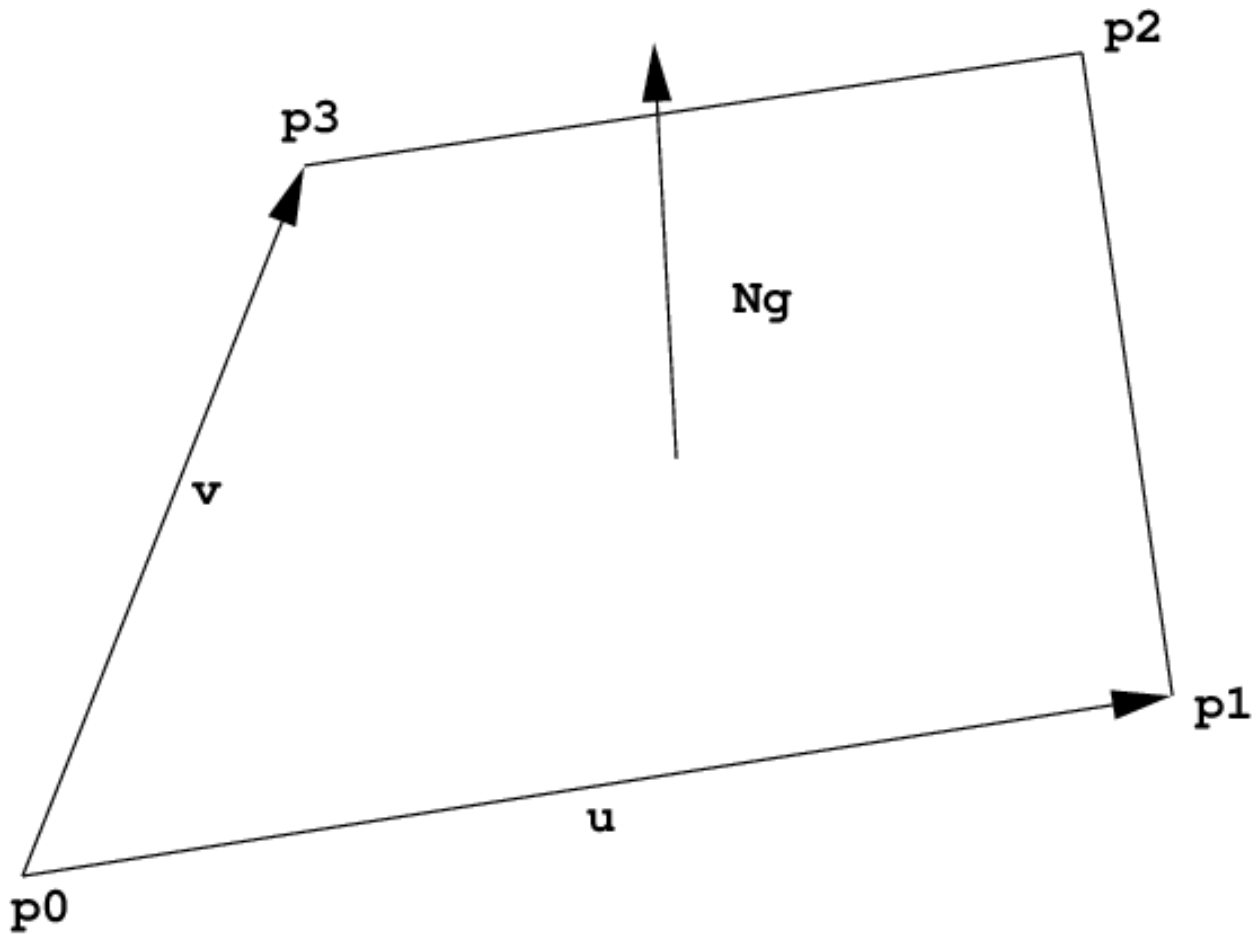

Quad meshes are created by passing `RTC_GEOMETRY_TYPE_QUAD` to the `rtcNewGeometry` function call. The quad indices can be specified by setting an index buffer (`RTC_BUFFER_TYPE_INDEX` type) and the quad vertices by setting a vertex buffer (`RTC_BUFFER_TYPE_VERTEX` type). See `rtcSetGeometryBuffer` and `rtcSetSharedGeometryBuffer` for more details on how to set buffers. The index buffer contains an array of four 32-bit indices per quad (`RTC_FORMAT_UINT4` format), and the number of primitives is inferred from the size of that buffer. The vertex buffer contains an array of single precision x, y, z floating point coordinates (`RTC_FORMAT_FLOAT3` format), and the number of vertices is inferred from the size of that buffer. The vertex buffer can be at most 16 GB large.

A quad is internally handled as a pair of two triangles v_0, v_1, v_3 and v_2, v_3, v_1 , with the u'/v' coordinates of the second triangle corrected by $u = 1-u'$ and $v = 1-v'$ to produce a quad parameterization where u and v are in the range 0 to 1. Thus the parameterization of a quad uses the first vertex p_0 as base point, and the vector $p_1 - p_0$ as u -direction, and $p_3 - p_0$ as v -direction. Thus vertex attributes t_0, t_1, t_2, t_3 can be bilinearly interpolated over the quadrilateral the following way:

$$t_{uv} = (1-v)((1-u)*t_0 + u*t_1) + v*((1-u)*t_3 + u*t_2)$$

Mixed triangle/quad meshes are supported by encoding a triangle as a quad, which can be achieved by replicating the last triangle vertex ($v_0, v_1, v_2 \rightarrow v_0, v_1, v_2, v_2$). This way the second triangle is a line (which can never get hit), and the parameterization of the first triangle is compatible with the standard triangle parameterization.

A quad whose vertices are laid out counter-clockwise has its geometry normal pointing upwards outside the front face, like illustrated in the following picture.

For multi-segment motion blur, the number of time steps must be first specified using the `rtcSetGeometryTimeStepCount` call. Then a vertex buffer for each time step can be set using different buffer slots, and all these buffers must have the same stride and size.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_GRID

NAME

```
RTC_GEOMETRY_TYPE_GRID - grid geometry type
```

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCGeometry geometry =
    rtcNewGeometry(device, RTC_GEOMETRY_TYPE_GRID);
```

DESCRIPTION

Grid meshes are created by passing `RTC_GEOMETRY_TYPE_GRID` to the `rtcNewGeometry` function call, and contain an array of grid primitives. This array of grids can be specified by setting up a grid buffer (with `RTC_BUFFER_TYPE_GRID` type and `RTC_FORMAT_GRID` format) and the grid mesh vertices by setting a vertex buffer (`RTC_BUFFER_TYPE_VERTEX` type). See `rtcSetGeometryBuffer` and `rtcSetSharedGeometryBuffer` for more details on how to set buffers. The number of grid primitives in the grid mesh is inferred from the size of the grid buffer.

The vertex buffer contains an array of single precision `x`, `y`, `z` floating point coordinates (`RTC_FORMAT_FLOAT3` format), and the number of vertices is inferred from the size of that buffer.

Each grid in the grid buffer is of the type `RTCGrid`:

```
struct RTCGrid
{
    unsigned int startVertexID;
    unsigned int stride;
    unsigned short width,height;
};
```

The `RTCGrid` structure describes a 2D grid of vertices (with respect to the vertex buffer of the grid mesh). The `width` and `height` members specify the number of vertices in `u` and `v` direction, e.g. setting both `width` and `height` to 3 sets up a 3×3 vertex grid. The maximum allowed `width` and `height` is 32767. The `startVertexID` specifies the ID of the top-left vertex in the vertex grid, while the `stride` parameter specifies a stride (in number of vertices) used to step to the next row.

A vertex grid of dimensions `width` and `height` is treated as a $(width-1) \times (height-1)$ grid of quads (triangle-pairs), with the same shared edge handling as for regular quad meshes. However, the `u/v` coordinates have the uniform range `[0..1]` for an entire vertex grid. The `u` direction follows the `width` of the grid while the `v` direction the `height`.

For multi-segment motion blur, the number of time steps must be first specified using the `rtcSetGeometryTimeStepCount` call. Then a vertex buffer for each time step can be set using different buffer slots, and all these buffers must have the same stride and size.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

    rtcNewGeometry(device, RTC_GEOMETRY_TYPE_SUBDIVISION);
```

DESCRIPTION

Catmull-Clark subdivision meshes are supported, including support for edge creases, vertex creases, holes, non-manifold geometry, and face-varying interpolation. The number of vertices per face can be in the range of 3 to 15 vertices (triangles, quadrilateral, pentagons, etc).

Subdivision meshes are created by passing `RTC_GEOMETRY_TYPE_SUBDIVISION` to the `rtcNewGeometry` function. Various buffers need to be set by the application to set up the subdivision mesh. See `rtcSetGeometryBuffer` and `rtcSetSharedGeometryBuffer` for more details on how to set buffers. The face buffer (`RTC_BUFFER_TYPE_FACE` type and `RTC_FORMAT_UINT` format) contains the number of edges/indices of each face (3 to 15), and the number of faces is inferred from the size of this buffer. The index buffer (`RTC_BUFFER_TYPE_INDEX` type) contains multiple (3 to 15) 32-bit vertex indices (`RTC_FORMAT_UINT` format) for each face, and the number of edges is inferred from the size of this buffer. The vertex buffer (`RTC_BUFFER_TYPE_VERTEX` type) stores an array of single precision x, y, z floating point coordinates (`RTC_FORMAT_FLOAT3` format), and the number of vertices is inferred from the size of this buffer.

Optionally, the application may set additional index buffers using different buffer slots if multiple topologies are required for face-varying interpolation. The standard vertex buffers (`RTC_BUFFER_TYPE_VERTEX`) are always bound to the geometry topology (topology 0) thus use `RTC_BUFFER_TYPE_INDEX` with buffer slot 0. User vertex data interpolation may use different topologies as described later.

Optionally, the application can set up the hole buffer (`RTC_BUFFER_TYPE_HOLE`) which contains an array of 32-bit indices (`RTC_FORMAT_UINT` format) of faces that should be considered non-existing in all topologies. The number of holes is inferred from the size of this buffer.

Optionally, the application can fill the level buffer (`RTC_BUFFER_TYPE_LEVEL`) with a tessellation rate for each of the edges of each face. This buffer must have the same size as the index buffer. The tessellation level is a positive floating point value (`RTC_FORMAT_FLOAT` format) that specifies how many quads along the edge should be generated during tessellation. If no level buffer is specified, a level of 1 is used. The maximally supported edge level is 4096, and larger levels are clamped to that value. Note that edges may be shared between (typically 2) faces. To guarantee a watertight tessellation, the level of these shared edges should be identical. A uniform tessellation rate for an entire subdivision mesh can be set by using the `rtcSetGeometryTessellationRate` function. The existence of a level buffer has precedence over the uniform tessellation rate.

Optionally, the application can fill the sparse edge crease buffers to make edges appear sharper. The edge crease index buffer (`RTC_BUFFER_TYPE_EDGE_CREASE_INDEX`) contains an array of pairs of 32-bit vertex indices (`RTC_FORMAT_UINT2` format) that specify unoriented edges in the geometry topology. The edge crease weight buffer (`RTC_BUFFER_TYPE_EDGE_CREASE_WEIGHT`) stores for each of these crease edges a positive floating point weight (`RTC_FORMAT_FLOAT` format). The number of edge creases is inferred from the size of these buffers, which has to be identical. The larger a weight, the sharper the edge. Specifying a weight of infinity is supported and marks an edge

as infinitely sharp. Storing an edge multiple times with the same crease weight is allowed, but has lower performance. Storing an edge multiple times with different crease weights results in undefined behavior. For a stored edge (i,j), the reverse direction edges (j,i) do not have to be stored, as both are considered the same unoriented edge. Edge crease features are shared between all topologies.

Optionally, the application can fill the sparse vertex crease buffers to make vertices appear sharper. The vertex crease index buffer (RTC_BUFFER_TYPE_VERTEX_CREASE_INDEX), contains an array of 32-bit vertex indices (RTC_FORMAT_UINT format) to specify a set of vertices from the geometry topology. The vertex crease weight buffer (RTC_BUFFER_TYPE_VERTEX_CREASE_WEIGHT) specifies for each of these vertices a positive floating point weight (RTC_FORMAT_FLOAT format). The number of vertex creases is inferred from the size of these buffers, and has to be identical. The larger a weight, the sharper the vertex. Specifying a weight of infinity is supported and makes the vertex infinitely sharp. Storing a vertex multiple times with the same crease weight is allowed, but has lower performance. Storing a vertex multiple times with different crease weights results in undefined behavior. Vertex crease features are shared between all topologies.

Subdivision modes can be used to force linear interpolation for parts of the subdivision mesh; see `rtcSetGeometrySubdivisionMode` for more details.

For multi-segment motion blur, the number of time steps must be first specified using the `rtcSetGeometryTimeStepCount` call. Then a vertex buffer for each time step can be set using different buffer slots, and all these buffers have to have the same stride and size.

Also see tutorial [Subdivision Geometry](#) for an example of how to create subdivision surfaces.

Parameterization

The parameterization for subdivision faces is different for quadrilaterals and non-quadrilateral faces.

The parameterization of a quadrilateral face uses the first vertex `p0` as base point, and the vector `p1 - p0` as u-direction and `p3 - p0` as v-direction.

The parameterization for all other face types (with number of vertices not equal 4), have a special parameterization where the subpatch ID `n` (of the `n`-th quadrilateral that would be obtained by a single subdivision step) and the local hit location inside this quadrilateral are encoded in the UV coordinates. The following code extracts the sub-patch ID `i` and local UVs of this subpatch:

```
unsigned int l = floorf(0.5f*U);
unsigned int h = floorf(0.5f*V);
unsigned int i = 4*h+1;
float u = 2.0f*fracf(0.5f*U)-0.5f;
float v = 2.0f*fracf(0.5f*V)-0.5f;
```

This encoding allows local subpatch UVs to be in the range $[-0.5, 1.5[$ thus negative subpatch UVs can be passed to `rtcInterpolate` to sample subpatches slightly out of bounds. This can be useful to calculate derivatives using finite differences if required. The encoding further has the property that one can just move the value `u` (or `v`) on a subpatch by adding `du` (or `dv`) to the special UV encoding as long as it does not fall out of the $[-0.5, 1.5[$ range.

To smoothly interpolate vertex attributes over the subdivision surface we recommend using the `rtcInterpolate` function, which will apply the standard subdivision rules for interpolation and automatically takes care of the special UV encoding for non-quadrilaterals.

Face-Varying Data

Face-varying interpolation is supported through multiple topologies per subdivision mesh and binding such topologies to vertex attribute buffers to interpolate. This way, texture coordinates may use a different topology with additional boundaries to construct separate UV regions inside one subdivision mesh.

Each such topology *i* has a separate index buffer (specified using `RTC_BUFFER_TYPE_INDEX` with buffer slot *i*) and separate subdivision mode that can be set using `rtcSetGeometrySubdivisionMode`. A vertex attribute buffer `RTC_BUFFER_TYPE_VERTEX_ATTRIBUTE` bound to a buffer slot *j* can be assigned to use a topology for interpolation using the `rtcSetGeometryVertexAttributeTopology` call.

The face buffer (`RTC_BUFFER_TYPE_FACE` type) is shared between all topologies, which means that the *n*-th primitive always has the same number of vertices (e.g. being a triangle or a quad) for each topology. However, the indices of the topologies themselves may be different.

EXIT STATUS

On failure `NULL` is returned and an error code is set that can be queried using `rtcGetDeviceError`.

DESCRIPTION

Curves with per vertex radii are supported with linear, cubic Bézier, cubic B-spline, and cubic Hermite bases. Such curve geometries are created by passing `RTC_GEOMETRY_TYPE_FLAT_LINEAR_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_BEZIER_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_BSPLINE_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_HERMITE_CURVE`, `RTC_GEOMETRY_TYPE_FLAT_CATMULL_ROM_CURVE`, `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_FLAT_BEZIER_CURVE`, `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_FLAT_BSPLINE_CURVE`, `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_FLAT_HERMITE_CURVE`, `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_FLAT_CATMULL_ROM_CURVE`, `RTC_GEOMETRY_TYPE_CONE_LINEAR_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_LINEAR_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_BEZIER_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_BSPLINE_CURVE`, `RTC_GEOMETRY_TYPE_ROUND_HERMITE_CURVE`, or `RTC_GEOMETRY_TYPE_ROUND_CATMULL_ROM_CURVE` to the `rtcNewGeometry` function. The curve indices can be specified through an index buffer (`RTC_BUFFER_TYPE_INDEX`) and the curve vertices through a vertex buffer (`RTC_BUFFER_TYPE_VERTEX`). For the Hermite basis a tangent buffer (`RTC_BUFFER_TYPE_TANGENT`), normal oriented curves a normal buffer (`RTC_BUFFER_TYPE_NORMAL`), and for normal oriented Hermite curves a normal derivative buffer (`RTC_BUFFER_TYPE_NORMAL_DERIVATIVE`) has to get specified additionally. See `rtcSetGeometryBuffer` and `rtcSetSharedGeometryBuffer` for more details on how to set buffers.

The index buffer contains an array of 32-bit indices (`RTC_FORMAT_UINT` format), each pointing to the first control vertex in the vertex buffer, but also to the first tangent in the tangent buffer, and first normal in the normal buffer if these buffers are present.

The vertex buffer stores each control vertex in the form of a single precision position and radius stored in (x, y, z, r) order in memory (`RTC_FORMAT_FLOAT4` format). The number of vertices is inferred from the size of this buffer. The radii may be smaller than zero but the interpolated radii should always be greater or equal to zero. Similarly, the tangent buffer stores the derivative of each control vertex (x, y, z, r order and `RTC_FORMAT_FLOAT4` format) and the normal buffer stores a single precision normal per control vertex (x, y, z order and `RTC_FORMAT_FLOAT3` format).

Linear Basis

For the linear basis the indices point to the first of 2 consecutive control points in the vertex buffer. The first control point is the start and the second control point the end of the line segment. When constructing hair strands in this basis, the end-point can be shared with the start of the next line segment.

For the linear basis the user optionally can provide a flags buffer of type `RTC_BUFFER_TYPE_FLAGS` which contains bytes that encode if the left neighbor segment (`RTC_CURVE_FLAG_NEIGHBOR_LEFT` flag) and/or right neighbor segment (`RTC_CURVE_FLAG_NEIGHBOR_RIGHT` flags) exist (see *RTCCurveFlags*). If this buffer is not set, than the left/right neighbor bits are automatically calculated base on the index buffer (left segment exists if $\text{segment}(\text{id}-1)+1 == \text{segment}(\text{id})$ and right segment exists if $\text{segment}(\text{id}+1)-1 == \text{segment}(\text{id})$).

A left neighbor segment is assumed to end at the start vertex of the current segment, and to start at the previous vertex in the vertex buffer. Similarly, the right neighbor segment is assumed to start at the end vertex of the current segment, and to end at the next vertex in the vertex buffer.

Only when the left and right bits are properly specified the current segment can properly attach to the left and/or right neighbor, otherwise the touching area may not get rendered properly.

Bézier Basis

For the cubic Bézier basis the indices point to the first of 4 consecutive control points in the vertex buffer. These control points use the cubic Bézier basis, where the first control point represents the start point of the curve, and the 4th control point the end point of the curve. The Bézier basis is interpolating, thus the curve does go exactly through the first and fourth control vertex.

B-spline Basis

For the cubic B-spline basis the indices point to the first of 4 consecutive control points in the vertex buffer. These control points make up a cardinal cubic B-spline (implicit equidistant knot vector). This basis is not interpolating, thus the curve does in general not go through any of the control points directly. A big advantage of this basis is that 3 control points can be shared for two continuous neighboring curve segments, e.g. the curves (p_0, p_1, p_2, p_3) and (p_1, p_2, p_3, p_4) are C^1 continuous. This feature make this basis a good choice to construct continuous multi-segment curves, as memory consumption can be kept minimal.

Hermite Basis

For the cubic Hermite basis the indices point to the first of 2 consecutive points in the vertex buffer, and the first of 2 consecutive tangents in the tangent buffer. These two points and two tangents make up a cubic Hermite curve. This basis is interpolating, thus does exactly go through the first and second control point, and the first order derivative at the begin and end matches exactly the value specified in the tangent buffer. When connecting two segments continuously, the end point and tangent of the previous segment can be shared. Different versions of Catmull-Rom splines can be easily constructed using the Hermite basis, by calculating a proper tangent buffer from the control points.

Catmull-Rom Basis

For the Catmull-Rom basis the indices point to the first of 4 consecutive control points in the vertex buffer. This basis goes through p_1 and p_2 , with tangents $(p_2-p_0)/2$ and $(p_3-p_1)/2$.

Flat Curves

The `RTC_GEOMETRY_TYPE_FLAT_*` flat mode is a fast mode designed to render distant hair. In this mode the curve is rendered as a connected sequence of ray facing quads. Individual quads are considered to have subpixel size, and zooming onto the curve might show geometric artifacts. The number of quads to subdivide into can be specified through the `rtcSetGeometryTessellationRate` function. By default the tessellation rate is 4.

Normal Oriented Curves

The `RTC_GEOMETRY_TYPE_NORMAL_ORIENTED_*` mode is a mode designed to render blades of grass. In this mode a vertex spline has to get specified as for the previous modes, but additionally a normal spline is required. If the Hermite basis is used, the `RTC_BUFFER_TYPE_NORMAL` and `RTC_BUFFER_TYPE_NORMAL_DERIVATIVE` buffers have both to be set.

The curve is rendered as a flat band whose center approximately follows the provided vertex spline, whose half width approximately follows the provided radius spline, and whose normal orientation approximately follows the provided normal spline.

To intersect the normal oriented curve, we perform a newton-raphson style intersection of a ray with a tensor product surface of a linear basis (perpendicular to the curve) and cubic Bézier basis (along the curve). We use a guide curve and its derivatives to construct the control points of that surface. The guide curve is defined by a sweep surface defined by sweeping a line centered at the vertex spline location along the curve. At each parameter value the half width of the line matches the radius spline, and the direction matches the cross product of the normal from the normal spline and tangent of the vertex spline. Note that this construction does not work when the provided normals are parallel to the curve direction. For this reason the provided normals should best be kept as perpendicular to the curve direction as possible.

Round Curves

In the `RTC_GEOMETRY_TYPE_ROUND_*` round mode, a real geometric surface is rendered for the curve, which is more expensive but allows closeup views.

For the linear basis the round mode renders a cone that tangentially touches a start-sphere and end-sphere. The start sphere is rendered when no previous segments is indicated by the neighbor bits. The end sphere is always rendered but parts that lie inside the next segment are clipped away (if that next segment exists). This way a curve is closed on both ends and the interior will render properly as long as only neighboring segments penetrate into a segment. For this to work properly it is important that the flags buffer is properly populated with neighbor information.

For the cubic polynomial bases, the round mode renders a sweep surface by sweeping a varying radius circle tangential along the curve. As a limitation, the radius of the curve has to be smaller than the curvature radius of the curve at each location on the curve.

The intersection with the curve segment stores the parametric hit location along the curve segment as u -coordinate (range 0 to +1).

For flat curves, the v -coordinate is set to the normalized distance in the range -1 to +1. For normal oriented curves the v -coordinate is in the range 0 to 1. For the linear basis and in round mode the v -coordinate is set to zero.

In flat mode, the geometry normal N_g is set to the tangent of the curve at the hit location. In round mode and for normal oriented curves, the geometry normal N_g is set to the non-normalized geometric normal of the surface.

For multi-segment motion blur, the number of time steps must be first specified using the `rtcSetGeometryTimeStepCount` call. Then a vertex buffer for each time step can be set using different buffer slots, and all these buffers must have the same stride and size. For the Hermite basis also a tangent buffer has to be set for each time step and for normal oriented curves a normal buffer has to be specified for each time step.

Also see tutorials [Hair](#) and [Curves](#) for examples of how to create and use curve geometries.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_POINT

NAME

```
RTC_GEOMETRY_TYPE_SPHERE_POINT -
    point geometry spheres

RTC_GEOMETRY_TYPE_DISC_POINT -
    point geometry with ray-oriented discs

RTC_GEOMETRY_TYPE_ORIENTED_DISC_POINT -
    point geometry with normal-oriented discs
```

SYNOPSIS

```
#include <embree3/rtcore.h>

rtcNewGeometry(device, RTC_GEOMETRY_TYPE_SPHERE_POINT);
rtcNewGeometry(device, RTC_GEOMETRY_TYPE_DISC_POINT);
rtcNewGeometry(device, RTC_GEOMETRY_TYPE_ORIENTED_DISC_POINT);
```

DESCRIPTION

Points with per vertex radii are supported with sphere, ray-oriented discs, and normal-oriented discs geometric representations. Such point geometries are created by passing `RTC_GEOMETRY_TYPE_SPHERE_POINT`, `RTC_GEOMETRY_TYPE_DISC_POINT`, or `RTC_GEOMETRY_TYPE_ORIENTED_DISC_POINT` to the `rtcNewGeometry` function. The point vertices can be specified through a vertex buffer (`RTC_BUFFER_TYPE_VERTEX`). For the normal oriented discs a normal buffer (`RTC_BUFFER_TYPE_NORMAL`) has to get specified additionally. See `rtcSetGeometryBuffer` and `rtcSetSharedGeometryBuffer` for more details on how to set buffers.

The vertex buffer stores each control vertex in the form of a single precision position and radius stored in (x, y, z, r) order in memory (`RTC_FORMAT_FLOAT4` format). The number of vertices is inferred from the size of this buffer. Similarly, the normal buffer stores a single precision normal per control vertex (x, y, z order and `RTC_FORMAT_FLOAT3` format).

In the `RTC_GEOMETRY_TYPE_SPHERE_POINT` mode, a real geometric surface is rendered for the curve, which is more expensive but allows closeup views.

The `RTC_GEOMETRY_TYPE_DISC_POINT` flat mode is a fast mode designed to render distant points. In this mode the point is rendered as a ray facing disc.

The `RTC_GEOMETRY_TYPE_ORIENTED_DISC_POINT` mode is a mode designed as a midpoint geometrically between ray facing discs and spheres. In this mode the point is rendered as a normal oriented disc.

For all point types, only the hit distance and geometry normal is returned as hit information, u and v are set to zero.

For multi-segment motion blur, the number of time steps must be first specified using the `rtcSetGeometryTimeStepCount` call. Then a vertex buffer for each time step can be set using different buffer slots, and all these buffers must have the same stride and size.

Also see tutorial [Points] for an example of how to create and use point geometries.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_USER

NAME

RTC_GEOMETRY_TYPE_USER - user geometry type

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCGeometry geometry =
    rtcNewGeometry(device, RTC_GEOMETRY_TYPE_USER);
```

DESCRIPTION

User-defined geometries contain a number of user-defined primitives, just like triangle meshes contain multiple triangles. The shape of the user-defined primitives is specified through registered callback functions, which enable extending Embree with arbitrary types of primitives.

User-defined geometries are created by passing `RTC_GEOMETRY_TYPE_USER` to the `rtcNewGeometry` function call. One has to set the number of primitives (see `rtcSetGeometryUserPrimitiveCount`), a user data pointer (see `rtcSetGeometryUserData`), a bounding function closure (see `rtcSetGeometryBoundsFunction`), as well as user-defined intersect (see `rtcSetGeometryIntersectFunction`) and occluded (see `rtcSetGeometryOccludedFunction`) callback functions. The bounding function is used to query the bounds of all time steps of a user primitive, while the intersect and occluded callback functions are called to intersect the primitive with a ray. The user data pointer is passed to each callback invocation and can be used to point to the application's representation of the user geometry.

The creation of a user geometry typically looks the following:

```
RTCGeometry geometry = rtcNewGeometry(device, RTC_GEOMETRY_TYPE_USER);
rtcSetGeometryUserPrimitiveCount(geometry, numPrimitives);
rtcSetGeometryUserData(geometry, userGeometryRepresentation);
rtcSetGeometryBoundsFunction(geometry, boundsFunction);
rtcSetGeometryIntersectFunction(geometry, intersectFunction);
rtcSetGeometryOccludedFunction(geometry, occludedFunction);
```

Please have a look at the `rtcSetGeometryBoundsFunction`, `rtcSetGeometryIntersectFunction`, and `rtcSetGeometryOccludedFunction` functions on the implementation of the callback functions.

Primitives of a user geometry are ignored during rendering when their bounds are empty, thus bounds have lower>upper in at least one dimension.

See tutorial [User Geometry](#) for an example of how to use the user-defined geometries.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_INSTANCE

NAME

```
RTC_GEOMETRY_TYPE_INSTANCE - instance geometry type
```

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCGeometry geometry =
    rtcNewGeometry(device, RTC_GEOMETRY_TYPE_INSTANCE);
```

DESCRIPTION

Embree supports instancing of scenes using affine transformations (3×3 matrix plus translation). As the instanced scene is stored only a single time, even if instanced to multiple locations, this feature can be used to create very complex scenes with small memory footprint.

Embree supports both single-level instancing and multi-level instancing. The maximum instance nesting depth is `RTC_MAX_INSTANCE_LEVEL_COUNT`; it can be configured at compile-time using the constant `EMBREE_MAX_INSTANCE_LEVEL_COUNT`. Users should adapt this constant to their needs: instances nested any deeper are silently ignored in release mode, and cause assertions in debug mode.

Instances are created by passing `RTC_GEOMETRY_TYPE_INSTANCE` to the `rtcNewGeometry` function call. The instanced scene can be set using the `rtcSetGeometryInstancedScene` call, and the affine transformation can be set using the `rtcSetGeometryTransform` function.

Please note that `rtcCommitScene` on the instanced scene should be called first, followed by `rtcCommitGeometry` on the instance, followed by `rtcCommitScene` for the top-level scene containing the instance.

If a ray hits the instance, the `geomID` and `primID` members of the hit are set to the geometry ID and primitive ID of the hit primitive in the instanced scene, and the `instID` member of the hit is set to the geometry ID of the instance in the top-level scene.

The instancing scheme can also be implemented using user geometries. To achieve this, the user geometry code should set the `instID` member of the intersection context to the geometry ID of the instance, then trace the transformed ray, and finally set the `instID` field of the intersection context again to `-1`. The `instID` field is copied automatically by each primitive intersector into the `instID` field of the hit structure when the primitive is hit. See the [User Geometry](#) tutorial for an example.

For multi-segment motion blur, the number of time steps must be first specified using the `rtcSetGeometryTimeStepCount` function. Then a transformation for each time step can be specified using the `rtcSetGeometryTransform` function.

See tutorials [Instanced Geometry](#) and [Multi Level Instancing](#) for examples of how to use instances.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

RTCCurveFlags

NAME

```
RTCCurveFlags - per segment flags for curve geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>
```

```
enum RTCCurveFlags { RTC_CURVE_FLAG_NEIGHBOR_LEFT = (1 << 0),  
RTC_CURVE_FLAG_NEIGHBOR_RIGHT = (1 << 1) };
```

DESCRIPTION

The RTCCurveFlags type is used for linear curves to determine if the left and/or right neighbor segment exist. Therefore one attaches a buffer of type RTC_BUFFER_TYPE_FLAGS to the curve geometry which stores an individual byte per curve segment.

If the RTC_CURVE_FLAG_NEIGHBOR_LEFT flag in that byte is enabled for a curve segment, then the left segment exists (which starts one vertex before the start vertex of the current curve) and the current segment is rendered to properly attach to that segment.

If the RTC_CURVE_FLAG_NEIGHBOR_RIGHT flag in that byte is enabled for a curve segment, then the right segment exists (which ends one vertex after the end vertex of the current curve) and the current segment is rendered to properly attach to that segment.

When not properly specifying left and right flags for linear curves, the rendering at the ending of these curves may not look correct, in particular when round linear curves are viewed from the inside.

EXIT STATUS

rtcRetainGeometry

NAME

```
rtcRetainGeometry - increments the geometry reference count
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
void rtcRetainGeometry(RTCGeometry geometry);
```

DESCRIPTION

Geometry objects are reference counted. The `rtcRetainGeometry` function increments the reference count of the passed geometry object (`geometry` argument). This function together with `rtcReleaseGeometry` allows to use the internal reference counting in a C++ wrapper class to handle the ownership of the object.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewGeometry, *rtcReleaseGeometry*

rtcReleaseGeometry

NAME

rtcReleaseGeometry - decrements the geometry reference count

SYNOPSIS

```
#include <embree3/rtcore.h>
void rtcReleaseGeometry(RTCGeometry geometry);
```

DESCRIPTION

Geometry objects are reference counted. The `rtcReleaseGeometry` function decrements the reference count of the passed geometry object (`geometry` argument). When the reference count falls to 0, the geometry gets destroyed.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewGeometry, *rtcRetainGeometry*

rtcCommitGeometry

NAME

```
rtcCommitGeometry - commits geometry changes
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
void rtcCommitGeometry(RTCGeometry geometry);
```

DESCRIPTION

The `rtcCommitGeometry` function is used to commit all geometry changes performed to a geometry (`geometry` parameter). After a geometry gets modified, this function must be called to properly update the internal state of the geometry to perform interpolations using `rtcInterpolate` or to commit a scene containing the geometry using `rtcCommitScene`.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcInterpolate, rtcCommitScene

rtcEnableGeometry

NAME

```
rtcEnableGeometry - enables the geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>
void rtcEnableGeometry(RTCGeometry geometry);
```

DESCRIPTION

The `rtcEnableGeometry` function enables the specified geometry (`geometry` argument). Only enabled geometries are rendered. Each geometry is enabled by default at construction time.

After enabling a geometry, the scene containing that geometry must be committed using `rtcCommitScene` for the change to have effect.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryTimeStepCount

NAME

```
rtcSetGeometryTimeStepCount - sets the number of time steps of the
geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryTimeStepCount(
    RTCGeometry geometry,
    unsigned int timeStepCount
);
```

DESCRIPTION

The `rtcSetGeometryTimeStepCount` function sets the number of time steps for multi-segment motion blur (`timeStepCount` parameter) of the specified geometry (`geometry` parameter).

For triangle meshes (`RTC_GEOMETRY_TYPE_TRIANGLE`), quad meshes (`RTC_GEOMETRY_TYPE_QUAD`), curves (`RTC_GEOMETRY_TYPE_CURVE`), points (`RTC_GEOMETRY_TYPE_POINT`), and subdivision geometries (`RTC_GEOMETRY_TYPE_SUBDIVISION`), the number of time steps directly corresponds to the number of vertex buffer slots available (`RTC_BUFFER_TYPE_VERTEX` buffer type). For these geometries, one vertex buffer per time step must be specified when creating multi-segment motion blur geometries.

For instance geometries (`RTC_GEOMETRY_TYPE_INSTANCE`), a transformation must be specified for each time step (see `rtcSetGeometryTransform`).

For user geometries, the registered bounding callback function must provide a bounding box per primitive and time step, and the intersection and occlusion callback functions should properly intersect the motion-blurred geometry at the ray time.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcNewGeometry, rtcSetGeometryTimeRange

rtcSetGeometryTimeRange

NAME

```
rtcSetGeometryTimeRange - sets the time range for a motion blur geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryTimeRange(
    RTCGeometry geometry,
    float startTime,
    float endTime
);
```

DESCRIPTION

The `rtcSetGeometryTimeRange` function sets a time range which defines the start (and end time) of the first (and last) time step of a motion blur geometry. The time range is defined relative to the camera shutter interval [0,1] but it can be arbitrary. Thus the `startTime` can be smaller, equal, or larger 0, indicating a geometry whose animation definition start before, at, or after the camera shutter opens. Similar the `endTime` can be smaller, equal, or larger than 1, indicating a geometry whose animation definition ends after, at, or before the camera shutter closes. The `startTime` has to be smaller or equal to the `endTime`.

The default time range when this function is not called is the entire camera shutter [0,1]. For best performance at most one time segment of the piece wise linear definition of the motion should fall outside the shutter window to the left and to the right. Thus do not set the `startTime` or `endTime` too far outside the [0,1] interval for best performance.

This time range feature will also allow geometries to appear and disappear during the camera shutter time if the specified time range is a sub range of [0,1].

Please also have a look at the `rtcSetGeometryTimeStepCount` function to see how to define the time steps for the specified time range.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryVertexAttributeCount

NAME

```
rtcSetGeometryVertexAttributeCount - sets the number of vertex
attributes of the geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryVertexAttributeCount(
    RTCGeometry geometry,
    unsigned int vertexAttributeCount
);
```

DESCRIPTION

The `rtcSetGeometryVertexAttributeCount` function sets the number of slots (`vertexAttributeCount` parameter) for vertex attribute buffers (`RTC_BUFFER_TYPE_VERTEX_ATTRIBUTE`) that can be used for the specified geometry (`geometry` parameter).

This function is supported only for triangle meshes (`RTC_GEOMETRY_TYPE_TRIANGLE`), quad meshes (`RTC_GEOMETRY_TYPE_QUAD`), curves (`RTC_GEOMETRY_TYPE_CURVE`), points (`RTC_GEOMETRY_TYPE_POINT`), and subdivision geometries (`RTC_GEOMETRY_TYPE_SUBDIVISION`).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryMask

NAME

rtcSetGeometryMask - sets the geometry mask

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryMask(
    RTCGeometry geometry,
    unsigned int mask
);
```

DESCRIPTION

The `rtcSetGeometryMask` function sets a 32-bit geometry mask (`mask` argument) for the specified geometry (`geometry` argument).

This geometry mask is used together with the ray mask stored inside the `mask` field of the ray. The primitives of the geometry are hit by the ray only if the bitwise `and` operation of the geometry mask with the ray mask is not 0. This feature can be used to disable selected geometries for specifically tagged rays, e.g. to disable shadow casting for certain geometries.

Ray masks are disabled in Embree by default at compile time, and can be enabled through the `EMBREE_RAY_MASK` parameter in CMake. One can query whether ray masks are enabled by querying the `RTC_DEVICE_PROPERTY_RAY_MASK_SUPPORTED` device property using `rtcGetDeviceProperty`.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryBuildQuality

NAME

rtcSetGeometryBuildQuality - sets the build quality **for** the geometry

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryBuildQuality(
    RTCGeometry geometry,
    enum RTCBuildQuality quality
);
```

DESCRIPTION

The `rtcSetGeometryBuildQuality` function sets the build quality (quality argument) for the specified geometry (geometry argument). The per-geometry build quality is only a hint and may be ignored. Embree currently uses the per-geometry build quality when the scene build quality is set to `RTC_BUILD_QUALITY_LOW`. In this mode a two-level acceleration structure is build, and geometries build a separate acceleration structure using the geometry build quality. The per-geometry build quality can be one of:

- `RTC_BUILD_QUALITY_LOW`: Creates lower quality data structures, e.g. for dynamic scenes.
- `RTC_BUILD_QUALITY_MEDIUM`: Default build quality for most usages. Gives a good compromise between build and render performance.
- `RTC_BUILD_QUALITY_HIGH`: Creates higher quality data structures for final-frame rendering. Enables a spatial split builder for certain primitive types.
- `RTC_BUILD_QUALITY_REFIT`: Uses a BVH refitting approach when changing only the vertex buffer.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetSceneBuildQuality

rtcSetGeometryBuffer

NAME

rtcSetGeometryBuffer - assigns a view of a buffer to the geometry

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryBuffer(
    RTCGeometry geometry,
    enum RTCBufferType type,
    unsigned int slot,
    enum RTCFormat format,
    RTCBuffer buffer,
    size_t byteOffset,
    size_t byteStride,
    size_t itemCount
);
```

DESCRIPTION

The `rtcSetGeometryBuffer` function binds a view of a buffer object (`buffer` argument) to a geometry buffer type and slot (`type` and `slot` argument) of the specified geometry (`geometry` argument).

One can specify the start of the first buffer element in bytes (`byteOffset` argument), the byte stride between individual buffer elements (`byteStride` argument), the format of the buffer elements (`format` argument), and the number of elements to bind (`itemCount`).

The start address (`byteOffset` argument) and stride (`byteStride` argument) must be both aligned to 4 bytes, otherwise the `rtcSetGeometryBuffer` function will fail.

After successful completion of this function, the geometry will hold a reference to the buffer object.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcSetSharedGeometryBuffer, rtcSetNewGeometryBuffer

rtcSetSharedGeometryBuffer

NAME

```
rtcSetSharedGeometryBuffer - assigns a view of a shared data buffer
to a geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetSharedGeometryBuffer(
    RTCGeometry geometry,
    enum RTCBufferType type,
    unsigned int slot,
    enum RTCFormat format,
    const void* ptr,
    size_t byteOffset,
    size_t byteStride,
    size_t itemCount
);
```

DESCRIPTION

The `rtcSetSharedGeometryBuffer` function binds a view of a shared user-managed data buffer (`ptr` argument) to a geometry buffer type and slot (`type` and `slot` argument) of the specified geometry (`geometry` argument).

One can specify the start of the first buffer element in bytes (`byteOffset` argument), the byte stride between individual buffer elements (`byteStride` argument), the format of the buffer elements (`format` argument), and the number of elements to bind (`itemCount`).

The start address (`byteOffset` argument) and stride (`byteStride` argument) must be both aligned to 4 bytes; otherwise the `rtcSetGeometryBuffer` function will fail.

When the buffer will be used as a vertex buffer (`RTC_BUFFER_TYPE_VERTEX` and `RTC_BUFFER_TYPE_VERTEX_ATTRIBUTE`), the last buffer element must be readable using 16-byte SSE load instructions, thus padding the last element is required for certain layouts. E.g. a standard `float3` vertex buffer layout should add storage for at least one more float to the end of the buffer.

The buffer data must remain valid for as long as the buffer may be used, and the user is responsible for freeing the buffer data when no longer required.

Sharing buffers can significantly reduce the memory required by the application, thus we recommend using this feature. When enabling the `RTC_SCENE_FLAG_COMPACT` scene flag, the spatial index structures index into the vertex buffer, resulting in even higher memory savings.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcSetGeometryBuffer, *rtcSetNewGeometryBuffer*

rtcSetNewGeometryBuffer

NAME

```
rtcSetNewGeometryBuffer - creates and assigns a new data buffer to  
the geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void* rtcSetNewGeometryBuffer(
    RTCGeometry geometry,
    enum RTCBufferType type,
    unsigned int slot,
    enum RTCFormat format,
    size_t byteStride,
    size_t itemCount
);
```

DESCRIPTION

The `rtcSetNewGeometryBuffer` function creates a new data buffer of specified format (`format` argument), byte stride (`byteStride` argument), and number of items (`itemCount` argument), and assigns it to a geometry buffer slot (`type` and `slot` argument) of the specified geometry (`geometry` argument). The buffer data is managed internally and automatically freed when the geometry is destroyed.

The byte stride (`byteStride` argument) must be aligned to 4 bytes; otherwise the `rtcSetNewGeometryBuffer` function will fail.

The allocated buffer will be automatically over-allocated slightly when used as a vertex buffer, where a requirement is that each buffer element should be readable using 16-byte SSE load instructions.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcSetGeometryBuffer, *rtcSetSharedGeometryBuffer*

RTCFormat

NAME

RTCFormat - specifies format of data in buffers

SYNOPSIS

```
#include <embree3/rtcore_ray.h>

enum RTCFormat
{
    RTC_FORMAT_UINT,
    RTC_FORMAT_UINT2,
    RTC_FORMAT_UINT3,
    RTC_FORMAT_UINT4,

    RTC_FORMAT_FLOAT,
    RTC_FORMAT_FLOAT2,
    RTC_FORMAT_FLOAT3,
    RTC_FORMAT_FLOAT4,
    RTC_FORMAT_FLOAT5,
    RTC_FORMAT_FLOAT6,
    RTC_FORMAT_FLOAT7,
    RTC_FORMAT_FLOAT8,
    RTC_FORMAT_FLOAT9,
    RTC_FORMAT_FLOAT10,
    RTC_FORMAT_FLOAT11,
    RTC_FORMAT_FLOAT12,
    RTC_FORMAT_FLOAT13,
    RTC_FORMAT_FLOAT14,
    RTC_FORMAT_FLOAT15,
    RTC_FORMAT_FLOAT16,

    RTC_FORMAT_FLOAT3X4_ROW_MAJOR,
    RTC_FORMAT_FLOAT4X4_ROW_MAJOR,

    RTC_FORMAT_FLOAT3X4_COLUMN_MAJOR,
    RTC_FORMAT_FLOAT4X4_COLUMN_MAJOR,

    RTC_FORMAT_GRID,
};
```

DESCRIPTION

The `RTCFormat` structure defines the data format stored in data buffers provided to Embree using the *`rtcSetGeometryBuffer`*, *`rtcSetSharedGeometryBuffer`*, and *`rtcSetNewGeometryBuffer`* API calls.

The `RTC_FORMAT_UINT/2/3/4` format are used to specify that data buffers store unsigned integers, or unsigned integer vectors of size 2,3 or 4. This format has typically to get used when specifying index buffers, e.g. `RTC_FORMAT_UINT3` for triangle meshes.

The `RTC_FORMAT_FLOAT/2/3/4. . .` format are used to specify that data buffers store single precision floating point values, or vectors there of (size 2,3,4, etc.). This format is typically used to specify to format of vertex buffers, e.g. the `RTC_FORMAT_FLOAT3` type for vertex buffers of triangle meshes.

The `RTC_FORMAT_FLOAT3X4_ROW_MAJOR` and `RTC_FORMAT_FLOAT3X4_COLUMN_MAJOR` formats, specify a 3x4 floating point matrix layed out either row major or column major. The `RTC_FORMAT_FLOAT4X4_ROW_MAJOR` and `RTC_FORMAT_FLOAT4X4_COLUMN_MAJOR` formats, specify a 4x4 floating point matrix layed out either row major or column major. These matrix formats are used in the *`rtcSetGeometryTransform`* function in order to set a transformation matrix for geometries.

The `RTC_FORMAT_GRID` is a special data format used to specify grid primitives of layout `RTCGrid` when creating grid geometries (see *`RTC_GEOMETRY_TYPE_GRID`*).

RTCBufferType

NAME

RTCFormat - specifies format of data in buffers

SYNOPSIS

```
#include <embree3/rtcore_ray.h>

enum RTCBufferType
{
    RTC_BUFFER_TYPE_INDEX           = 0,
    RTC_BUFFER_TYPE_VERTEX         = 1,
    RTC_BUFFER_TYPE_VERTEX_ATTRIBUTE = 2,
    RTC_BUFFER_TYPE_NORMAL         = 3,
    RTC_BUFFER_TYPE_TANGENT        = 4,
    RTC_BUFFER_TYPE_NORMAL_DERIVATIVE = 5,

    RTC_BUFFER_TYPE_GRID           = 8,

    RTC_BUFFER_TYPE_FACE           = 16,
    RTC_BUFFER_TYPE_LEVEL          = 17,
    RTC_BUFFER_TYPE_EDGE_CREASE_INDEX = 18,
    RTC_BUFFER_TYPE_EDGE_CREASE_WEIGHT = 19,
    RTC_BUFFER_TYPE_VERTEX_CREASE_INDEX = 20,
    RTC_BUFFER_TYPE_VERTEX_CREASE_WEIGHT = 21,
    RTC_BUFFER_TYPE_HOLE           = 22,

    RTC_BUFFER_TYPE_FLAGS = 32
};
```

DESCRIPTION

The `RTCBufferType` structure defines slots to assign data buffers to using the `rtcSetGeometryBuffer`, `rtcSetSharedGeometryBuffer`, and `rtcSetNewGeometryBuffer` API calls.

For most geometry types the `RTC_BUFFER_TYPE_INDEX` slot is used to assign an index buffer, while the `RTC_BUFFER_TYPE_VERTEX` is used to assign the corresponding vertex buffer.

The `RTC_BUFFER_TYPE_VERTEX_ATTRIBUTE` slot can get used to assign arbitrary additional vertex data which can get interpolated using the `rtcInterpolate` API call.

The `RTC_BUFFER_TYPE_NORMAL`, `RTC_BUFFER_TYPE_TANGENT`, and `RTC_BUFFER_TYPE_NORMAL_DERIVATIVE` are special buffers required to assign per vertex normals, tangents, and normal derivatives for some curve types.

The `RTC_BUFFER_TYPE_GRID` buffer is used to assign the grid primitive buffer for grid geometries (see `RTC_GEOMETRY_TYPE_GRID`).

The `RTC_BUFFER_TYPE_FACE`, `RTC_BUFFER_TYPE_LEVEL`, `RTC_BUFFER_TYPE_EDGE_CREASE_INDEX`, `RTC_BUFFER_TYPE_EDGE_CREASE_WEIGHT`, `RTC_BUFFER_TYPE_VERTEX_CREASE_INDEX`,

RTC_BUFFER_TYPE_VERTEX_CREASE_WEIGHT, and RTC_BUFFER_TYPE_HOLE are special buffers required to create subdivision meshes (see *RTC_GEOMETRY_TYPE_SUBDIVISION*).

The RTC_BUFFER_TYPE_FLAGS can get used to add additional flag per primitive of a geometry, and is currently only used for linear curves.

EXIT STATUS

rtcGetGeometryBufferData

NAME

```
rtcGetGeometryBufferData - gets pointer to  
the first buffer view element
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
void* rtcGetGeometryBufferData(  
    RTCGeometry geometry,  
    enum RTCBufferType type,  
    unsigned int slot  
);
```

DESCRIPTION

The `rtcGetGeometryBufferData` function returns a pointer to the first element of the buffer view attached to the specified buffer type and slot (type and slot argument) of the geometry (geometry argument).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcSetGeometryBuffer, rtcSetSharedGeometryBuffer, rtcSetNewGeometryBuffer

rtcUpdateGeometryBuffer

NAME

```
rtcUpdateGeometryBuffer - marks a buffer view bound to the geometry  
as modified
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
void rtcUpdateGeometryBuffer(  
    RTCGeometry geometry,  
    enum RTCBufferType type,  
    unsigned int slot  
);
```

DESCRIPTION

The `rtcUpdateGeometryBuffer` function marks the buffer view bound to the specified buffer type and slot (type and slot argument) of a geometry (geometry argument) as modified.

If a data buffer is changed by the application, the `rtcUpdateGeometryBuffer` call must be invoked for that buffer. Each buffer view assigned to a buffer slot is initially marked as modified, thus this function needs to be called only when doing buffer modifications after the first `rtcCommitScene`.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryIntersectFilterFunction

NAME

```
rtcSetGeometryIntersectFilterFunction - sets the intersection filter
    for the geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCFilterFunctionNArguments
{
    int* valid;
    void* geometryUserPtr;
    const struct RTCIntersectContext* context;
    struct RTCRayN* ray;
    struct RTCHitN* hit;
    unsigned int N;
};

typedef void (*RTCFilterFunctionN)(
    const struct RTCFilterFunctionNArguments* args
);

void rtcSetGeometryIntersectFilterFunction(
    RTCGeometry geometry,
    RTCFilterFunctionN filter
);
```

DESCRIPTION

The `rtcSetGeometryIntersectFilterFunction` function registers an intersection filter callback function (`filter` argument) for the specified geometry (`geometry` argument).

Only a single callback function can be registered per geometry, and further invocations overwrite the previously set callback function. Passing `NULL` as function pointer disables the registered callback function.

The registered intersection filter function is invoked for every hit encountered during the `rtcIntersect`-type ray queries and can accept or reject that hit. The feature can be used to define a silhouette for a primitive and reject hits that are outside the silhouette. E.g. a tree leaf could be modeled with an alpha texture that decides whether hit points lie inside or outside the leaf.

If the `RTC_BUILD_QUALITY_HIGH` mode is set, the filter functions may be called multiple times for the same primitive hit. Further, rays hitting exactly the edge might also report two hits for the same surface. For certain use cases, the application may have to work around this limitation by collecting already reported hits (`geomID/primID` pairs) and ignoring duplicates.

The filter function callback of type `RTCFilterFunctionN` gets passed a number of arguments through the `RTCFilterFunctionNArguments` structure. The `valid` parameter of that structure points to an integer valid mask (0 means invalid and -1 means valid). The `geometryUserPtr` member is a user pointer optionally set per geometry through the `rtcSetGeometryUserData` function. The `context` member points to the intersection context passed to

the ray query function. The `ray` parameter points to `N` rays in SOA layout. The `hit` parameter points to `N` hits in SOA layout to test. The `N` parameter is the number of rays and hits in `ray` and `hit`. The hit distance is provided as the `tFar` value of the ray. If the hit geometry is instanced, the `instID` member of the ray is valid, and the ray and the potential hit are in object space.

The filter callback function has the task to check for each valid ray whether it wants to accept or reject the corresponding hit. To reject a hit, the filter callback function just has to write `0` to the integer valid mask of the corresponding ray. To accept the hit, it just has to leave the valid mask set to `-1`. The filter function is further allowed to change the hit and decrease the `tFar` value of the ray but it should not modify other ray data nor any inactive components of the ray or hit.

When performing ray queries using `rtcIntersect1`, it is guaranteed that the packet size is 1 when the callback is invoked. When performing ray queries using the `rtcIntersect4/8/16` functions, it is not generally guaranteed that the ray packet size (and order of rays inside the packet) passed to the callback matches the initial ray packet. However, under some circumstances these properties are guaranteed, and whether this is the case can be queried using `rtcGetDeviceProperty`. When performing ray queries using the stream API such as `rtcIntersect1M`, `rtcIntersect1Mp`, `rtcIntersectNM`, or `rtcIntersectNp` the order of rays and ray packet size of the callback function might change to either 1, 4, 8, or 16.

For many usage scenarios, repacking and re-ordering of rays does not cause difficulties in implementing the callback function. However, algorithms that need to extend the ray with additional data must use the `rayID` component of the ray to identify the original ray to access the per-ray data.

The implementation of the filter function can choose to implement a single code path that uses the ray access helper functions `RTCray_XXX` and hit access helper functions `RTCHit_XXX` to access ray and hit data. Alternatively the code can branch to optimized implementations for specific sizes of `N` and cast the `ray` and `hit` inputs to the proper packet types.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryOccludedFilterFunction

NAME

```
rtcSetGeometryOccludedFilterFunction - sets the occlusion filter
for the geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryOccludedFilterFunction(
    RTCGeometry geometry,
    RTCFilterFunctionN filter
);
```

DESCRIPTION

The `rtcSetGeometryOccludedFilterFunction` function registers an occlusion filter callback function (`filter` argument) for the specified geometry (`geometry` argument).

Only a single callback function can be registered per geometry, and further invocations overwrite the previously set callback function. Passing `NULL` as function pointer disables the registered callback function.

The registered intersection filter function is invoked for every hit encountered during the `rtcOccluded`-type ray queries and can accept or reject that hit. The feature can be used to define a silhouette for a primitive and reject hits that are outside the silhouette. E.g. a tree leaf could be modeled with an alpha texture that decides whether hit points lie inside or outside the leaf.

Please see the description of the `rtcSetGeometryIntersectFilterFunction` for a description of the filter callback function.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryIntersectFilterFunction

rtcFilterIntersection

NAME

`rtcFilterIntersection` - invokes the intersection filter function

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcFilterIntersection(
    const struct RTCIntersectFunctionNArguments* args,
    const struct RTCFilterFunctionNArguments* filterArgs
);
```

DESCRIPTION

The `rtcFilterIntersection` function can be called inside an `RTCIntersectFunctionN` callback function to invoke the intersection filter registered to the geometry and stored inside the context. For this an `RTCFilterFunctionNArguments` structure must be created (see `rtcSetGeometryIntersectFilterFunction`) which basically consists of a valid mask, a hit packet to filter, the corresponding ray packet, and the packet size. After the invocation of `rtcFilterIntersection`, only rays that are still valid (valid mask set to -1) should update a hit.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

rtcSetGeometryUserData

NAME

```
rtcSetGeometryUserData - sets the user-defined data pointer of the
geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryUserData(RTCGeometry geometry, void* userPtr);
```

DESCRIPTION

The `rtcSetGeometryUserData` function sets the user-defined data pointer (`userPtr` argument) for a geometry (`geometry` argument). This user data pointer is intended to be pointing to the application's representation of the geometry, and is passed to various callback functions. The application can use this pointer inside the callback functions to access its geometry representation.

The `rtcGetGeometryUserData` function can be used to query an already set user data pointer of a geometry.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryBoundsFunction

NAME

`rtcSetGeometryBoundsFunction` - sets a callback to query the bounding box of user-defined primitives

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCBoundsFunctionArguments
{
    void* geometryUserPtr;
    unsigned int primID;
    unsigned int timeStep;
    struct RTCBounds* bounds_o;
};

typedef void (*RTCBoundsFunction)(
    const struct RTCBoundsFunctionArguments* args
);

void rtcSetGeometryBoundsFunction(
    RTCGeometry geometry,
    RTCBoundsFunction bounds,
    void* userPtr
);
```

DESCRIPTION

The `rtcSetGeometryBoundsFunction` function registers a bounding box callback function (`bounds` argument) with payload (`userPtr` argument) for the specified user geometry (`geometry` argument).

Only a single callback function can be registered per geometry, and further invocations overwrite the previously set callback function. Passing `NULL` as function pointer disables the registered callback function.

The registered bounding box callback function is invoked to calculate axis-aligned bounding boxes of the primitives of the user-defined geometry during spatial acceleration structure construction. The bounding box callback of `RTCBoundsFunction` type is invoked with a pointer to a structure of type `RTCBoundsFunctionArguments` which contains various arguments, such as: the user data of the geometry (`geometryUserPtr` member), the ID of the primitive to calculate the bounds for (`primID` member), the time step at which to calculate the bounds (`timeStep` member), and a memory location to write the calculated bound to (`bounds_o` member).

In a typical usage scenario one would store a pointer to the internal representation of the user geometry object using `rtcSetGeometryUserData`. The callback function can then read that pointer from the `geometryUserPtr` field and calculate the proper bounding box for the requested primitive and time, and store that bounding box to the destination structure (`bounds_o` member).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryIntersectFunction

NAME

`rtcSetGeometryIntersectFunction` - sets the callback function to intersect a user geometry

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCIntersectFunctionNArguments
{
    int* valid;
    void* geometryUserPtr;
    unsigned int primID;
    struct RTCIntersectContext* context;
    struct RTCRayHitN* rayhit;
    unsigned int N;
    unsigned int geomID;
};

typedef void (*RTCIntersectFunctionN)(
    const struct RTCIntersectFunctionNArguments* args
);

void rtcSetGeometryIntersectFunction(
    RTCGeometry geometry,
    RTCIntersectFunctionN intersect
);
```

DESCRIPTION

The `rtcSetGeometryIntersectFunction` function registers a ray/primitive intersection callback function (`intersect` argument) for the specified user geometry (`geometry` argument).

Only a single callback function can be registered per geometry and further invocations overwrite the previously set callback function. Passing `NULL` as function pointer disables the registered callback function.

The registered callback function is invoked by `rtcIntersect`-type ray queries to calculate the intersection of a ray packet of variable size with one user-defined primitive. The callback function of type `RTCIntersectFunctionN` gets passed a number of arguments through the `RTCIntersectFunctionNArguments` structure. The value `N` specifies the ray packet size, `valid` points to an array of integers that specify whether the corresponding ray is valid (-1) or invalid (0), the `geometryUserPtr` member points to the geometry user data previously set through `rtcSetGeometryUserData`, the `context` member points to the intersection context passed to the ray query, the `rayhit` member points to a ray and hit packet of variable size `N`, and the `geomID` and `primID` member identifies the geometry ID and primitive ID of the primitive to intersect.

The ray component of the `rayhit` structure contains valid data, in particular the `tfar` value is the current closest hit distance found. All data inside the `hit` component of the `rayhit` structure are undefined and should not be read by the function.

The task of the callback function is to intersect each active ray from the ray packet with the specified user primitive. If the user-defined primitive is missed by a ray of the ray packet, the function should return without modifying the ray or hit. If an intersection of the user-defined primitive with the ray was found in the valid range (from `tnear` to `tfar`), it should update the hit distance of the ray (`tfar` member) and the hit (`u`, `v`, `Ng`, `instID`, `geomID`, `primID` members). In particular, the currently intersected instance is stored in the `instID` field of the intersection context, which must be deep copied into the `instID` member of the hit.

As a primitive might have multiple intersections with a ray, the intersection filter function needs to be invoked by the user geometry intersection callback for each encountered intersection, if filtering of intersections is desired. This can be achieved through the `rtcFilterIntersection` call.

Within the user geometry intersect function, it is safe to trace new rays and create new scenes and geometries.

When performing ray queries using `rtcIntersect1`, it is guaranteed that the packet size is 1 when the callback is invoked. When performing ray queries using the `rtcIntersect4/8/16` functions, it is not generally guaranteed that the ray packet size (and order of rays inside the packet) passed to the callback matches the initial ray packet. However, under some circumstances these properties are guaranteed, and whether this is the case can be queried using `rtcGetDeviceProperty`. When performing ray queries using the stream API such as `rtcIntersect1M`, `rtcIntersect1Mp`, `rtcIntersectNM`, or `rtcIntersectNp` the order of rays and ray packet size of the callback function might change to either 1, 4, 8, or 16.

For many usage scenarios, repacking and re-ordering of rays does not cause difficulties in implementing the callback function. However, algorithms that need to extend the ray with additional data must use the `rayID` component of the ray to identify the original ray to access the per-ray data.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryOccludedFunction

NAME

`rtcSetGeometryOccludedFunction` - sets the callback function to test a user geometry **for** occlusion

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCOccludedFunctionNArguments
{
    int* valid;
    void* geometryUserPtr;
    unsigned int primID;
    struct RTCIntersectContext* context;
    struct RTCRayN* ray;
    unsigned int N;
    unsigned int geomID;
};

typedef void (*RTCOccludedFunctionN)(
    const struct RTCOccludedFunctionNArguments* args
);

void rtcSetGeometryOccludedFunction(
    RTCGeometry geometry,
    RTCOccludedFunctionN filter
);
```

DESCRIPTION

The `rtcSetGeometryOccludedFunction` function registers a ray/primitive occlusion callback function (`filter` argument) for the specified user geometry (`geometry` argument).

Only a single callback function can be registered per geometry, and further invocations overwrite the previously set callback function. Passing `NULL` as function pointer disables the registered callback function.

The registered callback function is invoked by `rtcOccluded`-type ray queries to test whether the rays of a packet of variable size are occluded by a user-defined primitive. The callback function of type `RTCOccludedFunctionN` gets passed a number of arguments through the `RTCOccludedFunctionNArguments` structure. The value `N` specifies the ray packet size, `valid` points to an array of integers which specify whether the corresponding ray is valid (-1) or invalid (0), the `geometryUserPtr` member points to the geometry user data previously set through `rtcSetGeometryUserData`, the `context` member points to the intersection context passed to the ray query, the `ray` member points to a ray packet of variable size `N`, and the `geomID` and `primID` member identifies the geometry ID and primitive ID of the primitive to intersect.

The task of the callback function is to intersect each active ray from the ray packet with the specified user primitive. If the user-defined primitive is missed by a ray of the ray packet, the function should return without modifying the ray. If

an intersection of the user-defined primitive with the ray was found in the valid range (from `tnear` to `tfar`), it should set the `tfar` member of the ray to `-inf`.

As a primitive might have multiple intersections with a ray, the occlusion filter function needs to be invoked by the user geometry occlusion callback for each encountered intersection, if filtering of intersections is desired. This can be achieved through the `rtcFilterOcclusion` call.

Within the user geometry occlusion function, it is safe to trace new rays and create new scenes and geometries.

When performing ray queries using `rtcOccluded1`, it is guaranteed that the packet size is 1 when the callback is invoked. When performing ray queries using the `rtcOccluded4/8/16` functions, it is not generally guaranteed that the ray packet size (and order of rays inside the packet) passed to the callback matches the initial ray packet. However, under some circumstances these properties are guaranteed, and whether this is the case can be queried using `rtcGetDeviceProperty`. When performing ray queries using the stream API such as `rtcOccluded1M`, `rtcOccluded1Mp`, `rtcOccludedNM`, or `rtcOccludedNp` the order of rays and ray packet size of the callback function might change to either 1, 4, 8, or 16.

For many usage scenarios, repacking and re-ordering of rays does not cause difficulties in implementing the callback function. However, algorithms that need to extend the ray with additional data must use the `rayID` component of the ray to identify the original ray to access the per-ray data.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometryPointQueryFunction

NAME

```
rtcSetGeometryPointQueryFunction - sets the point query callback function
    for a geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCPointQueryFunctionArguments
{
    // the (world space) query object that was passed as an argument of rtcPointQuery.
    struct RTCPointQuery* query;

    // used for user input/output data. Will not be read or modified internally.
    void* userPtr;

    // primitive and geometry ID of primitive
    unsigned int primID;
    unsigned int geomID;

    // the context with transformation and instance ID stack
    struct RTCPointQueryContext* context;

    // scaling factor indicating whether the current instance transformation
    // is a similarity transformation.
    float similarityScale;
};

typedef bool (*RTCPointQueryFunction)(
    struct RTCPointQueryFunctionArguments* args
);

void rtcSetGeometryPointQueryFunction(
    RTCGeometry geometry,
    RTCPointQueryFunction queryFunc
);
```

DESCRIPTION

The `rtcSetGeometryPointQueryFunction` function registers a point query callback function (`queryFunc` argument) for the specified geometry (`geometry` argument).

Only a single callback function can be registered per geometry and further invocations overwrite the previously set callback function. Passing NULL as function pointer disables the registered callback function.

The registered callback function is invoked by *rtcPointQuery* for every primitive of the geometry that intersects the corresponding point query domain. The callback function of type `RTCPointQueryFunction` gets passed a number of arguments through the `RTCPointQueryFunctionArguments` structure. The query object is the original point query

object passed into *rtcPointQuery*, *usrPtr* is an arbitrary pointer to pass input into and store results of the callback function. The *primID*, *geomID* and *context* (see *rtcInitPointQueryContext* for details) can be used to identify the geometry data of the primitive.

A *RTCPointQueryFunction* can also be passed directly as an argument to *rtcPointQuery*. In this case the callback is invoked for all primitives in the scene that intersect the query domain. If a callback function is passed as an argument to *rtcPointQuery* and (a potentially different) callback function is set for a geometry with *rtcSetGeometryPointQueryFunction* both callback functions are invoked and the callback function passed to *rtcPointQuery* will be called before the geometry specific callback function.

If instancing is used, the parameter *similarityScale* indicates whether the current instance transform (top element of the stack in *context*) is a similarity transformation or not. Similarity transformations are composed of translation, rotation and uniform scaling and if a matrix *M* defines a similarity transformation, there is a scaling factor *D* such that for all *x,y*: $\text{dist}(Mx, My) = D * \text{dist}(x, y)$. In this case the parameter *scalingFactor* is this scaling factor *D* and otherwise it is 0. A valid similarity scale (*similarityScale* > 0) allows to compute distance information in instance space and scale the distances into world space (for example, to update the query radius, see below) by dividing the instance space distance with the similarity scale. If the current instance transform is not a similarity transform (*similarityScale* is 0), the distance computation has to be performed in world space to ensure correctness. In this case the instance to world transformations given with the *context* should be used to transform the primitive data into world space. Otherwise, the query location can be transformed into instance space which can be more efficient. If there is no instance transform, the similarity scale is 1.

The callback function will potentially be called for primitives outside the query domain for two reasons: First, the callback is invoked for all primitives inside a BVH leaf node since no geometry data of primitives is determined internally and therefore individual primitives are not culled (only their (aggregated) bounding boxes). Second, in case non similarity transformations are used, the resulting ellipsoidal query domain (in instance space) is approximated by its axis aligned bounding box internally and therefore inner nodes that do not intersect the original domain might intersect the approximative bounding box which results in unnecessary callbacks. In any case, the callbacks are conservative, i.e. if a primitive is inside the query domain a callback will be invoked but the reverse is not necessarily true.

For efficiency, the radius of the query object can be decreased (in world space) inside the callback function to improve culling of geometry during BVH traversal. If the query radius was updated, the callback function should return *true* to issue an update of internal traversal information. Increasing the radius or modifying the time or position of the query results in undefined behaviour.

Within the callback function, it is safe to call *rtcPointQuery* again, for example when implementing instancing manually. In this case the instance transformation should be pushed onto the stack in *context*. Embree will internally compute the point query information in instance space using the top element of the stack in *context* when *rtcPointQuery* is called.

For a reference implementation of a closest point traversal of triangle meshes using instancing and user defined instancing see the tutorial [ClosestPoint].

RTC_GEOMETRY_TYPE_INSTANCE, *rtcSetGeometryTransform*

rtcSetGeometryTransform

NAME

```
rtcSetGeometryTransform - sets the transformation for a particular  
time step of an instance geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
void rtcSetGeometryTransform(  
    RTCGeometry geometry,  
    unsigned int timeStep,  
    enum RTCFormat format,  
    const float* xfm  
);
```

DESCRIPTION

The `rtcSetGeometryTransform` function sets the local-to-world affine transformation (`xfm` parameter) of an instance geometry (`geometry` parameter) for a particular time step (`timeStep` parameter). The transformation is specified as a 3×4 matrix (3×3 linear transformation plus translation), for which the following formats (`format` parameter) are supported:

- `RTC_FORMAT_FLOAT3X4_ROW_MAJOR`: The 3×4 float matrix is laid out in row-major form.
- `RTC_FORMAT_FLOAT3X4_COLUMN_MAJOR`: The 3×4 float matrix is laid out in column-major form.
- `RTC_FORMAT_FLOAT4X4_COLUMN_MAJOR`: The 3×4 float matrix is laid out in column-major form as a 4×4 homogeneous matrix with the last row being equal to (0, 0, 0, 1).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_INSTANCE

rtcSetGeometryTransformQuaternion

NAME

```
rtcSetGeometryTransformQuaternion - sets the transformation for a particular
time step of an instance geometry as a decomposition of the
transformation matrix using quaternions to represent the rotation.
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryTransformQuaternion(
    RTCGeometry geometry,
    unsigned int timeStep,
    const struct RTCQuaternionDecomposition* qd
);
```

DESCRIPTION

The `rtcSetGeometryTransformQuaternion` function sets the local-to-world affine transformation (`qd` parameter) of an instance geometry (`geometry` parameter) for a particular time step (`timeStep` parameter). The transformation is specified as a *RTCQuaternionDecomposition*, which is a decomposition of an affine transformation that represents the rotational component of an affine transformation as a quaternion. This allows interpolating rotational transformations exactly using spherical linear interpolation (such as a turning wheel).

For more information about the decomposition see *RTCQuaternionDecomposition*. The quaternion given in the `RTCQuaternionDecomposition` struct will be normalized internally.

For correct results, the transformation matrices for all time steps must be set either using `rtcSetGeometryTransform` or `rtcSetGeometryTransformQuaternion`. Mixing both representations is not allowed. Spherical linear interpolation will be used, iff the transformation matrices are set with `rtcSetGeometryTransformQuaternion`.

For an example of this feature see the tutorial [Quaternion Motion Blur](#).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcInitQuaternionDecomposition, *rtcSetGeometryTransform*

rtcGetGeometryTransform

NAME

```
rtcGetGeometryTransform - returns the interpolated instance transformation for the specified time
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcGetGeometryTransform(
    RTCGeometry geometry,
    float time,
    enum RTCFormat format,
    void* xfm
);
```

DESCRIPTION

The `rtcGetGeometryTransform` function returns the interpolated local to world transformation (`xfm` parameter) of an instance geometry (`geometry` parameter) for a particular time (`time` parameter in range $[0, 1]$) in the specified format (`format` parameter).

Possible formats for the returned matrix are:

- `RTC_FORMAT_FLOAT3X4_ROW_MAJOR`: The 3×4 float matrix is laid out in row-major form.
- `RTC_FORMAT_FLOAT3X4_COLUMN_MAJOR`: The 3×4 float matrix is laid out in column-major form.
- `RTC_FORMAT_FLOAT4X4_COLUMN_MAJOR`: The 3×4 float matrix is laid out in column-major form as a 4×4 homogeneous matrix with last row equal to (0, 0, 0, 1).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_INSTANCE, *rtcSetGeometryTransform*

rtcSetGeometryTessellationRate

NAME

```
rtcSetGeometryTessellationRate - sets the tessellation rate of the
geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryTessellationRate(
    RTCGeometry geometry,
    float tessellationRate
);
```

DESCRIPTION

The `rtcSetGeometryTessellationRate` function sets the tessellation rate (`tessellationRate` argument) for the specified geometry (`geometry` argument). The tessellation rate can only be set for flat curves and subdivision geometries. For curves, the tessellation rate specifies the number of ray-facing quads per curve segment. For subdivision surfaces, the tessellation rate specifies the number of quads along each edge.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_CURVE, RTC_GEOMETRY_TYPE_SUBDIVISION

rtcSetGeometryTopologyCount

NAME

```
rtcSetGeometryTopologyCount - sets the number of topologies of  
a subdivision geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>  
  
void rtcSetGeometryTopologyCount(  
    RTCGeometry geometry,  
    unsigned int topologyCount  
);
```

DESCRIPTION

The `rtcSetGeometryTopologyCount` function sets the number of topologies (`topologyCount` parameter) for the specified subdivision geometry (`geometry` parameter). The number of topologies of a subdivision geometry must be greater or equal to 1.

To use multiple topologies, first the number of topologies must be specified, then the individual topologies can be configured using `rtcSetGeometrySubdivisionMode` and by setting an index buffer (`RTC_BUFFER_TYPE_INDEX`) using the topology ID as the buffer slot.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

RTC_GEOMETRY_TYPE_SUBDIVISION, *rtcSetGeometrySubdivisionMode*

rtcSetGeometrySubdivisionMode

NAME

```
rtcSetGeometrySubdivisionMode - sets the subdivision mode
of a subdivision geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometrySubdivisionMode(
    RTCGeometry geometry,
    unsigned int topologyID,
    enum RTCSubdivisionMode mode
);
```

DESCRIPTION

The `rtcSetGeometrySubdivisionMode` function sets the subdivision mode (`mode` parameter) for the topology (`topologyID` parameter) of the specified subdivision geometry (`geometry` parameter).

The subdivision modes can be used to force linear interpolation for certain parts of the subdivision mesh:

- `RTC_SUBDIVISION_MODE_NO_BOUNDARY`: Boundary patches are ignored. This way each rendered patch has a full set of control vertices.
- `RTC_SUBDIVISION_MODE_SMOOTH_BOUNDARY`: The sequence of boundary control points are used to generate a smooth B-spline boundary curve (default mode).
- `RTC_SUBDIVISION_MODE_PIN_CORNERS`: Corner vertices are pinned to their location during subdivision.
- `RTC_SUBDIVISION_MODE_PIN_BOUNDARY`: All vertices at the border are pinned to their location during subdivision. This way the boundary is interpolated linearly. This mode is typically used for texturing to also map texels at the border of the texture to the mesh.
- `RTC_SUBDIVISION_MODE_PIN_ALL`: All vertices at the border are pinned to their location during subdivision. This way all patches are linearly interpolated.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

RTC_GEOMETRY_TYPE_SUBDIVISION

rtcSetGeometryVertexAttributeTopology

NAME

```
rtcSetGeometryVertexAttributeTopology - binds a vertex
attribute to a topology of the geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcSetGeometryVertexAttributeTopology(
    RTCGeometry geometry,
    unsigned int vertexAttributeID,
    unsigned int topologyID
);
```

DESCRIPTION

The `rtcSetGeometryVertexAttributeTopology` function binds a vertex attribute buffer slot (`vertexAttributeID` argument) to a topology (`topologyID` argument) for the specified subdivision geometry (`geometry` argument). Standard vertex buffers are always bound to the default topology (topology 0) and cannot be bound differently. A vertex attribute buffer always uses the topology it is bound to when used in the `rtcInterpolate` and `rtcInterpolateN` calls.

A topology with ID `i` consists of a subdivision mode set through `rtcSetGeometrySubdivisionMode` and the index buffer bound to the index buffer slot `i`. This index buffer can assign indices for each face of the subdivision geometry that are different to the indices of the default topology. These new indices can for example be used to introduce additional borders into the subdivision mesh to map multiple textures onto one subdivision geometry.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcSetGeometrySubdivisionMode, rtcInterpolate, rtcInterpolateN

rtcSetGeometryDisplacementFunction

NAME

```
rtcSetGeometryDisplacementFunction - sets the displacement function
    for a subdivision geometry
```

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCDisplacementFunctionNArguments
{
    void* geometryUserPtr;
    RTCGeometry geometry;
    unsigned int primID;
    unsigned int timeStep;
    const float* u;
    const float* v;
    const float* Ng_x;
    const float* Ng_y;
    const float* Ng_z;
    float* P_x;
    float* P_y;
    float* P_z;
    unsigned int N;
};

typedef void (*RTCDisplacementFunctionN)(
    const struct RTCDisplacementFunctionNArguments* args
);

void rtcSetGeometryDisplacementFunction(
    RTCGeometry geometry,
    RTCDisplacementFunctionN displacement
);
```

DESCRIPTION

The `rtcSetGeometryDisplacementFunction` function registers a displacement callback function (displacement argument) for the specified subdivision geometry (geometry argument).

Only a single callback function can be registered per geometry, and further invocations overwrite the previously set callback function. Passing NULL as function pointer disables the registered callback function.

The registered displacement callback function is invoked to displace points on the subdivision geometry during spatial acceleration structure construction, during the `rtcCommitScene` call.

The callback function of type `RTCDisplacementFunctionN` is invoked with a number of arguments stored inside the `RTCDisplacementFunctionNArguments` structure. The provided user data pointer of the geometry (`geometryUserPtr` member) can be used to point to the application's representation of the subdivision mesh. A

number `N` of points to displace are specified in a structure of array layout. For each point to displace, the local patch UV coordinates (`u` and `v` arrays), the normalized geometry normal (`Ng_x`, `Ng_y`, and `Ng_z` arrays), and the position (`P_x`, `P_y`, and `P_z` arrays) are provided. The task of the displacement function is to use this information and change the position data.

The geometry handle (`geometry` member) and primitive ID (`primID` member) of the patch to displace are additionally provided as well as the time step `timeStep`, which can be important if the displacement is time-dependent and motion blur is used.

All passed arrays must be aligned to 64 bytes and properly padded to make wide vector processing inside the displacement function easily possible.

Also see tutorial [Displacement Geometry](#) for an example of how to use the displacement mapping functions.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

rtcGetGeometryFirstHalfEdge**NAME**

```
rtcGetGeometryFirstHalfEdge - returns the first half edge of a face
```

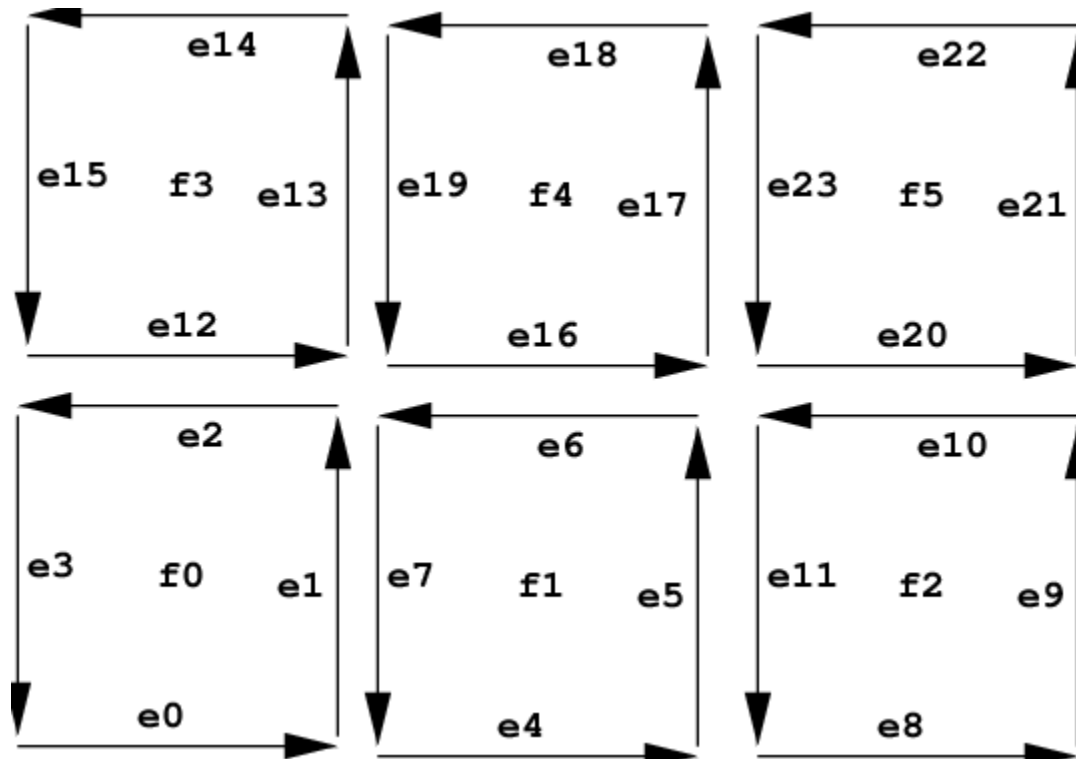

SYNOPSIS

```
#include <embree3/rtcore.h>

unsigned int rtcGetGeometryFirstHalfEdge(
    RTCGeometry geometry,
    unsigned int faceID
);
```

DESCRIPTION

The `rtcGetGeometryFirstHalfEdge` function returns the ID of the first half edge belonging to the specified face (`faceID` argument). For instance in the following example the first half edge of face `f1` is `e4`.

This function can only be used for subdivision geometries. As all topologies of a subdivision geometry share the same face buffer the function does not depend on the topology ID.

Here `f0` to `f7` are 8 quadrilateral faces with 4 vertices each. The edges `e0` to `e23` of these faces are shown with their orientation. For each face the ID of the edges corresponds to the slots the face occupies in the index array of the

geometry. E.g. as the indices of face f1 start at location 4 of the index array, the first edge is edge e4, the next edge e5, etc.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcGetGeometryFirstHalfEdge, *rtcGetGeometryFace*, *rtcGetGeometryOppositeHalfEdge*, *rtcGetGeometryNextHalfEdge*, *rtcGetGeometryPreviousHalfEdge*

rtcGetGeometryPreviousHalfEdge**NAME**

```
rtcGetGeometryPreviousHalfEdge - returns the previous half edge
```

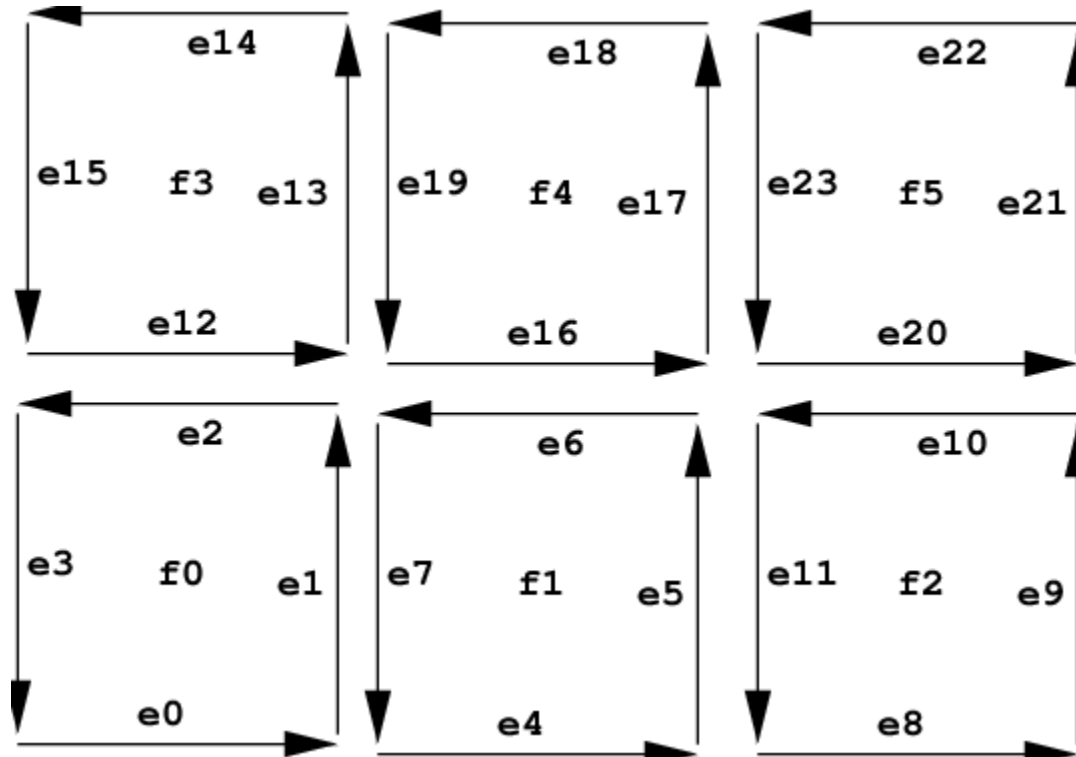

SYNOPSIS

```
#include <embree3/rtcore.h>

unsigned int rtcGetGeometryPreviousHalfEdge(
    RTCGeometry geometry,
    unsigned int edgeID
);
```

DESCRIPTION

The `rtcGetGeometryPreviousHalfEdge` function returns the ID of the previous half edge of the specified half edge (edgeID argument). For instance in the following example the previous half edge of e6 is e5.

This function can only be used for subdivision geometries. As all topologies of a subdivision geometry share the same face buffer the function does not depend on the topology ID.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcGetGeometryFirstHalfEdge, *rtcGetGeometryFace*, *rtcGetGeometryOppositeHalfEdge*, *rtcGetGeometryNextHalfEdge*, *rtcGetGeometryPreviousHalfEdge*

rtcGetGeometryOppositeHalfEdge**NAME**

```
rtcGetGeometryOppositeHalfEdge - returns the opposite half edge
```

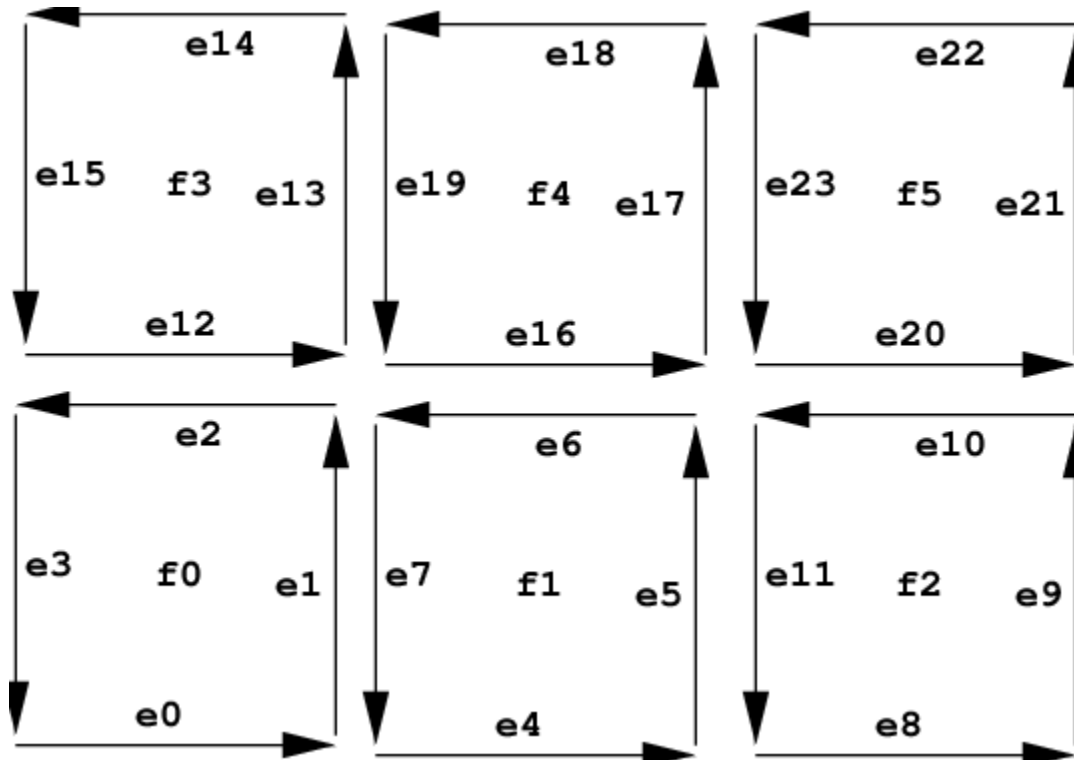

SYNOPSIS

```
#include <embree3/rtcore.h>

unsigned int rtcGetGeometryOppositeHalfEdge(
    RTCGeometry geometry,
    unsigned int topologyID,
    unsigned int edgeID
);
```

DESCRIPTION

The `rtcGetGeometryOppositeHalfEdge` function returns the ID of the opposite half edge of the specified half edge (`edgeID` argument) in the specified topology (`topologyID` argument). For instance in the following example the opposite half edge of `e6` is `e16`.

An opposite half edge does not exist if the specified half edge has either no neighboring face, or more than 2 neighboring faces. In these cases the function just returns the same edge `edgeID` again.

This function can only be used for subdivision geometries. The function depends on the topology as the topologies of a subdivision geometry have different index buffers assigned.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

NAME

```
rtcInterpolate - interpolates vertex attributes
```

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCInterpolateArguments
{
    RTCGeometry geometry;
    unsigned int primID;
    float u;
    float v;
    enum RTCBufferType bufferType;
    unsigned int bufferSlot;
    float* P;
    float* dPdu;
    float* dPdv;
    float* ddPdudu;
    float* ddPdvdv;
    float* ddPdudv;
    unsigned int valueCount;
};

void rtcInterpolate(
    const struct RTCInterpolateArguments* args
);
```

DESCRIPTION

The `rtcInterpolate` function smoothly interpolates per-vertex data over the geometry. This interpolation is supported for triangle meshes, quad meshes, curve geometries, and subdivision geometries. Apart from interpolating the vertex attribute itself, it is also possible to get the first and second order derivatives of that value. This interpolation ignores displacements of subdivision surfaces and always interpolates the underlying base surface.

The `rtcInterpolate` call gets passed a number of arguments inside a structure of type `RTCInterpolateArguments`. For some geometry (geometry parameter) this function smoothly interpolates the per-vertex data stored inside the specified geometry buffer (`bufferType` and `bufferSlot` parameters) to the u/v location (`u` and `v` parameters) of the primitive (`primID` parameter). The number of floating point values to interpolate and store to the destination arrays can be specified using the `valueCount` parameter. As interpolation buffer, one can specify vertex buffers (`RTC_BUFFER_TYPE_VERTEX`) and vertex attribute buffers (`RTC_BUFFER_TYPE_VERTEX_ATTRIBUTE`) as well.

The `rtcInterpolate` call stores `valueCount` number of interpolated floating point values to the memory location pointed to by `P`. One can avoid storing the interpolated value by setting `P` to `NULL`.

The first order derivative of the interpolation by `u` and `v` are stored at the `dPdu` and `dPdv` memory locations. One can avoid storing first order derivatives by setting both `dPdu` and `dPdv` to `NULL`.

The second order derivatives are stored at the `ddPdudu`, `ddPdvdv`, and `ddPdudv` memory locations. One can avoid storing second order derivatives by setting these three pointers to `NULL`.

To use `rtcInterpolate` for a geometry, all changes to that geometry must be properly committed using `rtcCommitGeometry`.

All input buffers and output arrays must be padded to 16 bytes, as the implementation uses 16-byte SSE instructions to read and write into these buffers.

See tutorial [Interpolation](#) for an example of using the `rtcInterpolate` function.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

rtcInterpolateN

rtcInterpolateN

NAME

```
rtcInterpolateN - performs N interpolations of vertex attribute data
```

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCInterpolateNArguments
{
    RTCGeometry geometry;
    const void* valid;
    const unsigned int* primIDs;
    const float* u;
    const float* v;
    unsigned int N;
    enum RTCBufferType bufferType;
    unsigned int bufferSlot;
    float* P;
    float* dPdu;
    float* dPdv;
    float* ddPdudu;
    float* ddPdvdv;
    float* ddPdudv;
    unsigned int valueCount;
};

void rtcInterpolateN(
    const struct RTCInterpolateNArguments* args
);
```

DESCRIPTION

The `rtcInterpolateN` is similar to `rtcInterpolate`, but performs `N` many interpolations at once. It additionally gets an array of `u/v` coordinates and a valid mask (`valid` parameter) that specifies which of these coordinates are valid. The valid mask points to `N` integers, and a value of `-1` denotes valid and `0` invalid. If the valid pointer is `NULL` all elements are considered valid. The destination arrays are filled in structure of array (SOA) layout. The value `N` must be divisible by 4.

To use `rtcInterpolateN` for a geometry, all changes to that geometry must be properly committed using `rtcCommitGeometry`.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

rtcNewBuffer

NAME

```
rtcNewBuffer - creates a new data buffer
```

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCBuffer rtcNewBuffer(
    RTCDevice device,
    size_t byteSize
);
```

DESCRIPTION

The `rtcNewBuffer` function creates a new data buffer object of specified size in bytes (`byteSize` argument) that is bound to the specified device (`device` argument). The buffer object is reference counted with an initial reference count of 1. The returned buffer object can be released using the `rtcReleaseBuffer` API call. The specified number of bytes are allocated at buffer construction time and deallocated when the buffer is destroyed.

When the buffer will be used as a vertex buffer (`RTC_BUFFER_TYPE_VERTEX` and `RTC_BUFFER_TYPE_VERTEX_ATTRIBUTE`), the last buffer element must be readable using 16-byte SSE load instructions, thus padding the last element is required for certain layouts. E.g. a standard `float3` vertex buffer layout should add storage for at least one more float to the end of the buffer.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcRetainBuffer, *rtcReleaseBuffer*

rtcNewSharedBuffer

NAME

rtcNewSharedBuffer - creates a **new** shared data buffer

SYNOPSIS

```
#include <embree3/rtcore.h>

RTCBuffer rtcNewSharedBuffer(
    RTCDevice device,
    void* ptr,
    size_t byteSize
);
```

DESCRIPTION

The `rtcNewSharedBuffer` function creates a new shared data buffer object bound to the specified device (`device` argument). The buffer object is reference counted with an initial reference count of 1. The buffer can be released using the `rtcReleaseBuffer` function.

At construction time, the pointer to the user-managed buffer data (`ptr` argument) including its size in bytes (`byteSize` argument) is provided to create the buffer. At buffer construction time no buffer data is allocated, but the buffer data provided by the application is used. The buffer data must remain valid for as long as the buffer may be used, and the user is responsible to free the buffer data when no longer required.

When the buffer will be used as a vertex buffer (`RTC_BUFFER_TYPE_VERTEX` and `RTC_BUFFER_TYPE_VERTEX_ATTRIBUTE`), the last buffer element must be readable using 16-byte SSE load instructions, thus padding the last element is required for certain layouts. E.g. a standard `float3` vertex buffer layout should add storage for at least one more float to the end of the buffer.

The data pointer (`ptr` argument) must be aligned to 4 bytes; otherwise the `rtcNewSharedBuffer` function will fail.

EXIT STATUS

On failure NULL is returned and an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcRetainBuffer, rtcReleaseBuffer

rtcRetainBuffer

NAME

```
rtcRetainBuffer - increments the buffer reference count
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcRetainBuffer(RTCBuffer buffer);
```

DESCRIPTION

Buffer objects are reference counted. The `rtcRetainBuffer` function increments the reference count of the passed buffer object (`buffer` argument). This function together with `rtcReleaseBuffer` allows to use the internal reference counting in a C++ wrapper class to handle the ownership of the object.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewBuffer, *rtcReleaseBuffer*

rtcReleaseBuffer

NAME

```
rtcReleaseBuffer - decrements the buffer reference count
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcReleaseBuffer(RTCBuffer buffer);
```

DESCRIPTION

Buffer objects are reference counted. The `rtcReleaseBuffer` function decrements the reference count of the passed buffer object (`buffer` argument). When the reference count falls to 0, the buffer gets destroyed.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewBuffer, *rtcRetainBuffer*

rtcGetBufferData

NAME

```
rtcGetBufferData - gets a pointer to the buffer data
```

SYNOPSIS

```
#include <embree3/rtcore.h>
void* rtcGetBufferData(RTCBuffer buffer);
```

DESCRIPTION

The `rtcGetBufferData` function returns a pointer to the buffer data of the specified buffer object (`buffer` argument).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

RTCRay

NAME

RTCRay - single ray structure

SYNOPSIS

```
#include <embree3/rtcore_ray.h>

struct RTC_ALIGN(16) RTCRay
{
    float org_x;           // x coordinate of ray origin
    float org_y;           // y coordinate of ray origin
    float org_z;           // z coordinate of ray origin
    float tnear;           // start of ray segment

    float dir_x;           // x coordinate of ray direction
    float dir_y;           // y coordinate of ray direction
    float dir_z;           // z coordinate of ray direction
    float time;           // time of this ray for motion blur

    float tfar;           // end of ray segment (set to hit distance)
    unsigned int mask;    // ray mask
    unsigned int id;     // ray ID
    unsigned int flags;   // ray flags
};
```

DESCRIPTION

The RTCRay structure defines the ray layout for a single ray. The ray contains the origin (`org_x`, `org_y`, `org_z` members), direction vector (`dir_x`, `dir_y`, `dir_z` members), and ray segment (`tnear` and `tfar` members). The ray direction does not have to be normalized, and only the parameter range specified by the `tnear`/`tfar` interval is considered valid.

The ray segment must be in the range $[0, \infty]$, thus ranges that start behind the ray origin are not allowed, but ranges can reach to infinity. For rays inside a ray stream, `tfar < tnear` identifies an inactive ray.

The ray further contains a motion blur time in the range $[0, 1]$ (`time` member), a ray mask (`mask` member), a ray ID (`id` member), and ray flags (`flags` member). The ray mask can be used to mask out some geometries for some rays (see `rtcSetGeometryMask` for more details). The ray ID can be used to identify a ray inside a callback function, even if the order of rays inside a ray packet or stream has changed. The ray flags are reserved.

The `embree3/rtcore_ray.h` header additionally defines the same ray structure in structure of array (SOA) layout for API functions accepting ray packets of size 4 (RTCRay4 type), size 8 (RTCRay8 type), and size 16 (RTCRay16 type). The header additionally defines an `RTCRayNt` template for ray packets of an arbitrary compile-time size.

RTCHit

RTCHit

NAME

RTCHit - single hit structure

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCHit
{
    float Ng_x;           // x coordinate of geometry normal
    float Ng_y;           // y coordinate of geometry normal
    float Ng_z;           // z coordinate of geometry normal

    float u;              // barycentric u coordinate of hit
    float v;              // barycentric v coordinate of hit

    unsigned int primID;  // geometry ID
    unsigned int geomID;  // primitive ID
    unsigned int instID[RTC_MAX_INSTANCE_LEVEL_COUNT]; // instance ID
};
```

DESCRIPTION

The `RTCHit` type defines the type of a ray/primitive intersection result. The hit contains the unnormalized geometric normal in object space at the hit location (`Ng_x`, `Ng_y`, `Ng_z` members), the barycentric u/v coordinates of the hit (`u` and `v` members), as well as the primitive ID (`primID` member), geometry ID (`geomID` member), and instance ID stack (`instID` member) of the hit. The parametric intersection distance is not stored inside the hit, but stored inside the `tfar` member of the ray.

The `embree3/rtcore_ray.h` header additionally defines the same hit structure in structure of array (SOA) layout for hit packets of size 4 (`RTCHit4` type), size 8 (`RTCHit8` type), and size 16 (`RTCHit16` type). The header additionally defines an `RTCHitNt` template for hit packets of an arbitrary compile-time size.

RTCRayHit

NAME

RTCRayHit - combined single ray/hit structure

SYNOPSIS

```
#include <embree3/rtcore_ray.h>

struct RTCORE_ALIGN(16) RTCRayHit
{
    struct RTCRay ray;
    struct RTCHit hit;
};
```

DESCRIPTION

The `RTCRayHit` structure is used as input for the `rtcIntersect`-type functions and stores the ray to intersect and some hit fields that hold the intersection result afterwards.

The `embree3/rtcore_ray.h` header additionally defines the same ray/hit structure in structure of array (SOA) layout for API functions accepting ray packets of size 4 (`RTCRayHit4` type), size 8 (`RTCRayHit8` type), and size 16 (`RTCRayHit16` type). The header additionally defines an `RTCRayHitNt` template to generate ray/hit packets of an arbitrary compile-time size.

RTCRayN

NAME

RTCRayN - ray packet of runtime size

SYNOPSIS

```
#include <embree3/rtcore_ray.h>

struct RTCRayN;

float& RTCRayN_org_x(RTCRayN* ray, unsigned int N, unsigned int i);
float& RTCRayN_org_y(RTCRayN* ray, unsigned int N, unsigned int i);
float& RTCRayN_org_z(RTCRayN* ray, unsigned int N, unsigned int i);
float& RTCRayN_tnear(RTCRayN* ray, unsigned int N, unsigned int i);

float& RTCRayN_dir_x(RTCRayN* ray, unsigned int N, unsigned int i);
float& RTCRayN_dir_y(RTCRayN* ray, unsigned int N, unsigned int i);
float& RTCRayN_dir_z(RTCRayN* ray, unsigned int N, unsigned int i);
float& RTCRayN_time (RTCRayN* ray, unsigned int N, unsigned int i);

float&      RTCRayN_tfar (RTCRayN* ray, unsigned int N, unsigned int i);
unsigned int& RTCRayN_mask (RTCRayN* ray, unsigned int N, unsigned int i);
unsigned int& RTCRayN_id   (RTCRayN* ray, unsigned int N, unsigned int i);
unsigned int& RTCRayN_flags(RTCRayN* ray, unsigned int N, unsigned int i);
```

DESCRIPTION

When the ray packet size is not known at compile time (e.g. when Embree returns a ray packet in the `RTCFilterFuncN` callback function), Embree uses the `RTCRayN` type for ray packets. These ray packets can only have sizes of 1, 4, 8, or 16. No other packet size will be used.

You can either implement different special code paths for each of these possible packet sizes and cast the ray to the appropriate ray packet type, or implement one general code path that uses the `RTCRayN_XXX` helper functions to access the ray packet components.

These helper functions get a pointer to the ray packet (`ray` argument), the packet size (`N` argument), and returns a reference to a component (e.g. x-component of origin) of the the `i`-th ray of the packet (`i` argument).

EXIT STATUS

RTHitN

NAME

RTHitN - hit packet of runtime size

SYNOPSIS

```
#include <embree3/rtcore.h>

struct HitN;

float& RTHitN_Ng_x(RTHitN* hit, unsigned int N, unsigned int i);
float& RTHitN_Ng_y(RTHitN* hit, unsigned int N, unsigned int i);
float& RTHitN_Ng_z(RTHitN* hit, unsigned int N, unsigned int i);

float& RTHitN_u(RTHitN* hit, unsigned int N, unsigned int i);
float& RTHitN_v(RTHitN* hit, unsigned int N, unsigned int i);

unsigned& RTHitN_primID(RTHitN* hit, unsigned int N, unsigned int i);
unsigned& RTHitN_geomID(RTHitN* hit, unsigned int N, unsigned int i);
unsigned& RTHitN_instID(RTHitN* hit, unsigned int N, unsigned int i, unsigned int_
↳level);
```

DESCRIPTION

When the hit packet size is not known at compile time (e.g. when Embree returns a hit packet in the `RTCFilterFuncN` callback function), Embree uses the `RTHitN` type for hit packets. These hit packets can only have sizes of 1, 4, 8, or 16. No other packet size will be used.

You can either implement different special code paths for each of these possible packet sizes and cast the hit to the appropriate hit packet type, or implement one general code path that uses the `RTHitN_XXX` helper functions to access hit packet components.

These helper functions get a pointer to the hit packet (`hit` argument), the packet size (`N` argument), and returns a reference to a component (e.g. x component of `Ng`) of the the `i`-th hit of the packet (`i` argument).

RTCrayHitN

NAME

RTCrayHitN - combined ray/hit packet of runtime size

SYNOPSIS

```
#include <embree3/rtcore_ray.h>

struct RTCrayHitN;

struct RTCrayN* RTCrayHitN_RayN(struct RTCrayHitN* rayhit, unsigned int N);
struct RTCHitN* RTCrayHitN_HitN(struct RTCrayHitN* rayhit, unsigned int N);
```

DESCRIPTION

When the packet size of a ray/hit structure is not known at compile time (e.g. when Embree returns a ray/hit packet in the `RTCIntersectFunctionN` callback function), Embree uses the `RTCrayHitN` type for ray packets. These ray/hit packets can only have sizes of 1, 4, 8, or 16. No other packet size will be used.

You can either implement different special code paths for each of these possible packet sizes and cast the ray/hit to the appropriate ray/hit packet type, or extract the `RTCrayN` and `RTCHitN` components using the `rtcGetRayN` and `rtcGetHitN` helper functions and use the `RTCrayN_XXX` and `RTCHitN_XXX` functions to access the ray and hit parts of the structure.

rtcInitIntersectContext

NAME

```
rtcInitIntersectContext - initializes the intersection context
```

SYNOPSIS

```
#include <embree3/rtcore.h>

enum RTCIntersectContextFlags
{
    RTC_INTERSECT_CONTEXT_FLAG_NONE,
    RTC_INTERSECT_CONTEXT_FLAG_INCOHERENT,
    RTC_INTERSECT_CONTEXT_FLAG_COHERENT,
};

struct RTCIntersectContext
{
    enum RTCIntersectContextFlags flags;
    RTCFilterFunctionN filter;

    #if RTC_MAX_INSTANCE_LEVEL_COUNT > 1
        unsigned int instStackSize;
    #endif

    unsigned int instID[RTC_MAX_INSTANCE_LEVEL_COUNT];

    #if RTC_MIN_WIDTH
        float minWidthDistanceFactor;
    #endif
};

void rtcInitIntersectContext(
    struct RTCIntersectContext* context
);
```

DESCRIPTION

A per ray-query intersection context (RTCIntersectContext type) is supported that can be used to configure intersection flags (flags member), specify a filter callback function (filter member), specify the chain of IDs of the current instance (instID and instStackSize members), and to attach arbitrary data to the query (e.g. per ray data).

The rtcInitIntersectContext function initializes the context to default values and should be called to initialize every intersection context. This function gets inlined, which minimizes overhead and allows for compiler optimizations.

The intersection context flag can be used to tune the behavior of the traversal algorithm. Using the RTC_INTERSECT_CONTEXT_FLAG_INCOHERENT flags uses an optimized traversal algorithm for incoherent rays (default), while RTC_INTERSECT_CONTEXT_FLAG_COHERENT uses an optimized traversal algorithm for coherent rays (e.g. primary camera rays).

Best primary ray performance can be obtained by using the ray stream API and setting the intersect context flag to `RTC_INTERSECT_CONTEXT_FLAG_COHERENT`. For secondary rays, it is typically better to use the `RTC_INTERSECT_CONTEXT_FLAG_INCOHERENT` flag, unless the rays are known to be very coherent too (e.g. for primary transparency rays).

A filter function can be specified inside the context. This filter function is invoked as a second filter stage after the per-geometry intersect or occluded filter function is invoked. Only rays that passed the first filter stage are valid in this second filter stage. Having such a per ray-query filter function can be useful to implement modifications of the behavior of the query, such as collecting all hits or accumulating transparencies. The support for the context filter function must be enabled for a scene by using the `RTC_SCENE_FLAG_CONTEXT_FILTER_FUNCTION` scene flag. In case of instancing this feature has to get enabled also for each instantiated scene.

The `minWidthDistanceFactor` value controls the target size of the curve radii when the min-width feature is enabled. Please see the `[rtcSetGeometryMaxRadiusScale]` function for more details on the min-width feature.

It is guaranteed that the pointer to the intersection context passed to a ray query is directly passed to the registered callback functions. This way it is possible to attach arbitrary data to the end of the intersection context, such as a per-ray payload.

Please note that the ray pointer is not guaranteed to be passed to the callback functions, thus reading additional data from the ray pointer passed to callbacks is not possible.

EXIT STATUS

No error code is set by this function.

rtcIntersect1, rtcOccluded1

rtcIntersect1

NAME

```
rtcIntersect1 - finds the closest hit for a single ray
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcIntersect1(
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRayHit* rayhit
);
```

DESCRIPTION

The `rtcIntersect1` function finds the closest hit of a single ray with the scene (`scene` argument). The provided ray/hit structure (`rayhit` argument) contains the ray to intersect and some hit output fields that are filled when a hit is found.

The user has to initialize the ray origin (`org` ray member), ray direction (`dir` ray member), ray segment (`tnear`, `tfar` ray members), and set the ray flags to `0` (`flags` ray member). If the scene contains motion blur geometries, also the ray time (`time` ray member) must be initialized to a value in the range $[0, 1]$. If ray masks are enabled at compile time, the ray mask (`mask` ray member) must be initialized as well. The ray segment has to be in the range $[0, \infty]$, thus ranges that start behind the ray origin are not valid, but ranges can reach to infinity. See Section *RTCRay* for the ray layout description.

The geometry ID (`geomID` hit member) of the hit data must be initialized to `RTC_INVALID_GEOMETRY_ID` (-1).

Further, an intersection context for the ray query function must be created and initialized (see `rtcInitIntersectContext`).

When no intersection is found, the ray/hit data is not updated. When an intersection is found, the hit distance is written into the `tfar` member of the ray and all hit data is set, such as unnormalized geometry normal in object space (`Ng` hit member), local hit coordinates (`u`, `v` hit member), instance ID stack (`instID` hit member), geometry ID (`geomID` hit member), and primitive ID (`primID` hit member). See Section *RTCHit* for the hit layout description.

If the instance ID stack has a prefix of values not equal to `RTC_INVALID_GEOMETRY_ID`, the instance ID on each level corresponds to the geometry ID of the hit instance of the higher-level scene, the geometry ID corresponds to the hit geometry inside the hit instanced scene, and the primitive ID corresponds to the *n*-th primitive of that geometry.

If level 0 of the instance ID stack is equal to `RTC_INVALID_GEOMETRY_ID`, the geometry ID corresponds to the hit geometry inside the top-level scene, and the primitive ID corresponds to the *n*-th primitive of that geometry.

The implementation makes no guarantees that primitives whose hit distance is exactly at (or very close to) `tnear` or `tfar` are hit or missed. If you want to exclude intersections at `tnear` just pass a slightly enlarged `tnear`, and if you want to include intersections at `tfar` pass a slightly enlarged `tfar`.

The intersection context (`context` argument) can specify flags to optimize traversal and a filter callback function to be invoked for every intersection. Further, the pointer to the intersection context is propagated to callback functions invoked during traversal and can thus be used to extend the ray with additional data. See Section *RTCIntersectContext* for more information.

The ray pointer passed to callback functions is not guaranteed to be identical to the original ray provided. To extend the ray with additional data to be accessed in callback functions, use the intersection context.

The ray/hit structure must be aligned to 16 bytes.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

SEE ALSO

rtcOccluded1

NAME

```
rtcOccluded1 - finds any hit for a single ray
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcOccluded1(
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRay* ray
);
```

DESCRIPTION

The `rtcOccluded1` function checks for a single ray (`ray` argument) whether there is any hit with the scene (`scene` argument).

The user must initialize the ray origin (`org` ray member), ray direction (`dir` ray member), ray segment (`tnear`, `tfar` ray members), and must set the ray flags to 0 (`flags` ray member). If the scene contains motion blur geometries, also the ray time (`time` ray member) must be initialized to a value in the range $[0, 1]$. If ray masks are enabled at compile time, the ray mask (`mask` ray member) must be initialized as well. The ray segment must be in the range $[0, \infty]$, thus ranges that start behind the ray origin are not valid, but ranges can reach to infinity. See Section *RTCRay* for the ray layout description.

When no intersection is found, the ray data is not updated. In case a hit was found, the `tfar` component of the ray is set to `-inf`.

The implementation makes no guarantees that primitives whose hit distance is exactly at (or very close to) `tnear` or `tfar` are hit or missed. If you want to exclude intersections at `tnear` just pass a slightly enlarged `tnear`, and if you want to include intersections at `tfar` pass a slightly enlarged `tfar`.

The intersection context (`context` argument) can specify flags to optimize traversal and a filter callback function to be invoked for every intersection. Further, the pointer to the intersection context is propagated to callback functions invoked during traversal and can thus be used to extend the ray with additional data. See Section *RTCIntersectContext* for more information.

The ray pointer passed to callback functions is not guaranteed to be identical to the original ray provided. To extend the ray with additional data to be accessed in callback functions, use the intersection context.

The ray must be aligned to 16 bytes.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

rtcIntersect4/8/16

NAME

```
rtcIntersect4/8/16 - finds the closest hits for a ray packet
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcIntersect4(
    const int* valid,
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRayHit4* rayhit
);

void rtcIntersect8(
    const int* valid,
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRayHit8* rayhit
);

void rtcIntersect16(
    const int* valid,
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRayHit16* rayhit
);
```

DESCRIPTION

The `rtcIntersect4/8/16` functions finds the closest hits for a ray packet of size 4, 8, or 16 (`rayhit` argument) with the scene (`scene` argument). The ray/hit input contains a ray packet and hit packet. See Section [rtcIntersect1](#) for a description of how to set up and trace rays.

A ray valid mask must be provided (`valid` argument) which stores one 32-bit integer (-1 means valid and 0 invalid) per ray in the packet. Only active rays are processed, and hit data of inactive rays is not changed.

The intersection context (`context` argument) can specify flags to optimize traversal and a filter callback function to be invoked for every intersection. Further, the pointer to the intersection context is propagated to callback functions invoked during traversal and can thus be used to extend the ray with additional data. See Section [RTCIntersectContext](#) for more information.

The ray pointer passed to callback functions is not guaranteed to be identical to the original ray provided. To extend the ray with additional data to be accessed in callback functions, use the intersection context.

The implementation of these functions is guaranteed to invoke callback functions always with the same ray packet size and ordering of rays as specified initially.

For `rtcIntersect4` the ray packet must be aligned to 16 bytes, for `rtcIntersect8` the alignment must be 32 bytes, and for `rtcIntersect16` the alignment must be 64 bytes.

The `rtcIntersect4`, `rtcIntersect8` and `rtcIntersect16` functions may change the ray packet size and ray order when calling back into intersect filter functions or user geometry callbacks. Under some conditions the application can assume packets to stay intact, which can be determined by querying the `RTC_DEVICE_PROPERTY_NATIVE_RAY4_SUPPORTED`, `RTC_DEVICE_PROPERTY_NATIVE_RAY8_SUPPORTED`, `RTC_DEVICE_PROPERTY_NATIVE_RAY16_SUPPORTED` properties through the `rtcGetDeviceProperty` function. See *[rtcGetDeviceProperty](#)* for more information.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

rtcOccluded4/8/16

NAME

```
rtcOccluded4/8/16 - finds any hits for a ray packet
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcOccluded4(
    const int* valid,
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRay4* ray
);

void rtcOccluded8(
    const int* valid,
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRay8* ray
);

void rtcOccluded16(
    const int* valid,
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRay16* ray
);
```

DESCRIPTION

The `rtcOccluded4/8/16` functions checks for each active ray of the ray packet of size 4, 8, or 16 (`ray` argument) whether there is any hit with the scene (`scene` argument). See Section *rtcOccluded1* for a description of how to set up and trace occlusion rays.

A ray valid mask must be provided (`valid` argument) which stores one 32-bit integer (-1 means valid and 0 invalid) per ray in the packet. Only active rays are processed, and hit data of inactive rays is not changed.

The intersection context (`context` argument) can specify flags to optimize traversal and a filter callback function to be invoked for every intersection. Further, the pointer to the intersection context is propagated to callback functions invoked during traversal and can thus be used to extend the ray with additional data. See Section `RTCIntersectContext` for more information.

The ray pointer passed to callback functions is not guaranteed to be identical to the original ray provided. To extend the ray with additional data to be accessed in callback functions, use the intersection context.

The implementation of these functions is guaranteed to invoke callback functions always with the same ray packet size and ordering of rays as specified initially.

For `rtcOccluded4` the ray packet must be aligned to 16 bytes, for `rtcOccluded8` the alignment must be 32 bytes, and for `rtcOccluded16` the alignment must be 64 bytes.

The `rtcOccluded4`, `rtcOccluded8` and `rtcOccluded16` functions may change the ray packet size and ray order when calling back into intersect filter functions or user geometry callbacks. Under some conditions the application can assume packets to stay intact, which can be determined by querying the `RTC_DEVICE_PROPERTY_NATIVE_RAY4_SUPPORTED`, `RTC_DEVICE_PROPERTY_NATIVE_RAY8_SUPPORTED`, `RTC_DEVICE_PROPERTY_NATIVE_RAY16_SUPPORTED` properties through the `rtcGetDeviceProperty` function. See *[rtcGetDeviceProperty](#)* for more information.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

rtcIntersect1M

NAME

```
rtcIntersect1M - finds the closest hits for a stream of M single
rays
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcIntersect1M(
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRayHit* rayhit,
    unsigned int M,
    size_t byteStride
);
```

DESCRIPTION

The `rtcIntersect1M` function finds the closest hits for a stream of `M` single rays (`rayhit` argument) with the scene (`scene` argument). The `rayhit` argument points to an array of ray and hit data with specified byte stride (`byteStride` argument) between the ray/hit structures. See Section *rtcIntersect1* for a description of how to set up and trace rays.

The intersection context (`context` argument) can specify flags to optimize traversal and a filter callback function to be invoked for every intersection. Further, the pointer to the intersection context is propagated to callback functions invoked during traversal and can thus be used to extend the ray with additional data. See Section `RTCIntersectContext` for more information.

The implementation of the stream ray query functions may re-order rays arbitrarily and re-pack rays into ray packets of different size. For this reason, callback functions may be invoked with an arbitrary packet size (of size 1, 4, 8, or 16) and different ordering as specified initially. For this reason, one may have to use the `rayID` component of the ray to identify the original ray, e.g. to access a per-ray payload.

A ray in a ray stream is considered inactive if its `tnear` value is larger than its `tfar` value.

The stream size `M` can be an arbitrary positive integer including 0. Each ray must be aligned to 16 bytes.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

rtcIntersectNp

NAME

```
rtcIntersectNp - finds the closest hits for a SOA ray stream of
size N
```

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcIntersectNp(
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRayHitNp* rayhit,
    unsigned int N
);
```

DESCRIPTION

The `rtcIntersectNp` function finds the closest hits for a SOA ray stream (rays argument) of size N (basically a large ray packet) with the scene (scene argument). The `rayhit` argument points to two structures of pointers with one pointer for each ray and hit component. Each of these pointers points to an array with the ray or hit component data for each ray or hit. This way the individual components of the SOA ray stream do not need to be stored sequentially in memory, which makes it possible to have large varying size ray packets in SOA layout. See Section [rtcIntersect1](#) for a description of how to set up and trace rays.

The intersection context (context argument) can specify flags to optimize traversal and a filter callback function to be invoked for every intersection. Further, the pointer to the intersection context is propagated to callback functions invoked during traversal and can thus be used to extend the ray with additional data. See Section `RTCIntersectContext` for more information.

The implementation of the stream ray query functions may re-order rays arbitrarily and re-pack rays into ray packets of different size. For this reason, callback functions may be invoked with an arbitrary packet size (of size 1, 4, 8, or 16) and different ordering as specified initially. For this reason, one may have to use the `rayID` component of the ray to identify the original ray, e.g. to access a per-ray payload.

A ray in a ray stream is considered inactive if its `tnear` value is larger than its `tfar` value.

The stream size N can be an arbitrary positive integer including 0. Each ray component array must be aligned to 16 bytes.

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

SEE ALSO

SYNOPSIS

```
#include <embree3/rtcore.h>

void rtcOccludedNp(
    RTCScene scene,
    struct RTCIntersectContext* context,
    struct RTCRayNp* ray,
    unsigned int N
);
```

DESCRIPTION

The `rtcOccludedNp` function checks whether there are any hits for a SOA ray stream (`ray` argument) of size `N` (basically a large ray packet) with the scene (`scene` argument). The ray argument points to a structure of pointers with one pointer for each ray component. Each of these pointers points to an array with the ray component data for each ray. This way the individual components of the SOA ray stream do not need to be stored sequentially in memory, which makes it possible to have large varying size ray packets in SOA layout. See Section *rtcOccluded1* for a description of how to set up and trace occlusion rays.

The intersection context (`context` argument) can specify flags to optimize traversal and a filter callback function to be invoked for every intersection. Further, the pointer to the intersection context is propagated to callback functions invoked during traversal and can thus be used to extend the ray with additional data. See Section `RTCIntersectContext` for more information.

The implementation of the stream ray query functions may re-order rays arbitrarily and re-pack rays into ray packets of different size. For this reason, callback functions may be invoked with an arbitrary packet size (of size 1, 4, 8, or 16) and different ordering as specified initially. For this reason, one may have to use the `rayID` component of the ray to identify the original ray, e.g. to access a per-ray payload.

A ray in a ray stream is considered inactive if its `tnear` value is larger than its `tfar` value.

The stream size `N` can be an arbitrary positive integer including 0. Each ray component array must be aligned to 16 bytes.

EXIT STATUS

rtcInitPointQueryContext

NAME

```
rtcInitPointQueryContext - initializes the context information (e.g.
    stack of (multilevel-)instance transformations) for point queries
```

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTC_ALIGN(16) RTCPointQueryContext
{
    // accumulated 4x4 column major matrices from world to instance space.
    float world2inst[RTC_MAX_INSTANCE_LEVEL_COUNT][16];

    // accumulated 4x4 column major matrices from instance to world space.
    float inst2world[RTC_MAX_INSTANCE_LEVEL_COUNT][16];

    // instance ids.
    unsigned int instID[RTC_MAX_INSTANCE_LEVEL_COUNT];

    // number of instances currently on the stack.
    unsigned int instStackSize;
};

void rtcInitPointQueryContext(
    struct RTCPointQueryContext* context
);
```

DESCRIPTION

A stack (`RTCPointQueryContext` type) which stores the IDs and instance transformations during a BVH traversal for a point query. The transformations are assumed to be affine transformations (3×3 matrix plus translation) and therefore the last column is ignored (see `RTC_GEOMETRY_TYPE_INSTANCE` for details).

The `rtcInitPointContext` function initializes the context to default values and should be called for initialization.

The context will be passed as an argument to the point query callback function (see `rtcSetGeometryPointQueryFunction`) and should be used to pass instance information down the instancing chain for user defined instancing (see tutorial [ClosestPoint] for a reference implementation of point queries with user defined instancing).

The context is an necessary argument to `rtcPointQuery` and Embree internally uses the topmost instance transformation of the stack to transform the point query into instance space.

EXIT STATUS

No error code is set by this function.

SEE ALSO

rtcPointQuery, *rtcSetGeometryPointQueryFunction*

rtcPointQuery

NAME

```
rtcPointQuery - traverses the BVH with a point query object
```

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTC_ALIGN(16) RTCPointQuery
{
    // location of the query
    float x;
    float y;
    float z;

    // radius and time of the query
    float radius;
    float time;
};

void rtcPointQuery(
    RTCScene scene,
    struct RTCPointQuery* query,
    struct RTCPointQueryContext* context,
    struct RTCPointQueryFunction* queryFunc,
    void* userPtr
);
```

DESCRIPTION

The `rtcPointQuery` function traverses the BVH using a `RTCPointQuery` object (query argument) and calls a user defined callback function (e.g. `queryFunc` argument) for each primitive of the scene (scene argument) that intersects the query domain.

The user has to initialize the query location (x, y and z member) and query radius in the range $[0, \infty]$. If the scene contains motion blur geometries, also the query time (time member) must be initialized to a value in the range $[0, 1]$.

Further, a `RTCPointQueryContext` (context argument) must be created and initialized. It contains ID and transformation information of the instancing hierarchy if (multilevel-)instancing is used. See *rtcInitPointQueryContext* for further information.

For every primitive that intersects the query domain, the callback function (`queryFunc` argument) is called, in which distance computations to the primitive can be implemented. The user will be provided with the `primID` and `geomID` of the according primitive, however, the geometry information (e.g. triangle index and vertex data) has to be determined manually. The `userPtr` argument can be used to input geometry data of the scene or output results of the point query (e.g. closest point currently found on surface geometry (see tutorial [ClosestPoint])).

The parameter `queryFunc` is optional and can be NULL, in which case the callback function is not invoked. However, a callback function can still get attached to a specific `RTCGeometry` object using *rtcSetGeometryPointQueryFunction*.

If a callback function is attached to a geometry and (a potentially different) callback function is passed as an argument to `rtcPointQuery`, both functions are called for the primitives of the according geometries.

The query radius can be decreased inside the callback function, which allows to efficiently cull parts of the scene during BVH traversal. Increasing the query radius and modifying time or location of the query will result in undefined behaviour.

The callback function will be called for all primitives in a leaf node of the BVH even if the primitive is outside the query domain, since Embree does not gather geometry information of primitives internally.

Point queries can be used with (multilevel)-instancing. However, care has to be taken when the instance transformation contains anisotropic scaling or sheering. In these cases distance computations have to be performed in world space to ensure correctness and the ellipsoidal query domain (in instance space) will be approximated with its axis aligned bounding box internally. Therefore, the callback function might be invoked even for primitives in inner BVH nodes that do not intersect the query domain. See [*rtcSetGeometryPointQueryFunction*](#) for details.

The point query structure must be aligned to 16 bytes.

SUPPORTED PRIMITIVES

Currently, all primitive types are supported by the point query API except of points (see `RTC_GEOMETRY_TYPE_POINT`), curves (see `RTC_GEOMETRY_TYPE_CURVE`) and subdivision surfaces (see `RTC_GEOMETRY_SUBDIVISION`).

EXIT STATUS

For performance reasons this function does not do any error checks, thus will not set any error flags on failure.

SEE ALSO

rtcSetGeometryPointQueryFunction, *rtcInitPointQueryContext*

rtcCollide

NAME

```
rtcCollide - intersects one BVH with another
```

SYNOPSIS

```
#include <embree3/rtcore.h>

struct RTCCollision {
    unsigned int geomID0, primID0;
    unsigned int geomID1, primID1;
};

typedef void (*RTCCollideFunc) (
    void* userPtr,
    RTCCollision* collisions,
    size_t num_collisions);

void rtcCollide (
    RTCScene hscene0,
    RTCScene hscene1,
    RTCCollideFunc callback,
    void* userPtr
);
```

DESCRIPTION

The `rtcCollide` function intersects the BVH of `hscene0` with the BVH of scene `hscene1` and calls a user defined callback function (e.g `callback` argument) for each pair of intersecting primitives between the two scenes. A user defined data pointer (`userPtr` argument) can also be passed in.

For every pair of primitives that may intersect each other, the callback function (`callback` argument) is called. The user will be provided with the `primID`'s and `geomID`'s of multiple potentially intersecting primitive pairs. Currently, only scene entirely composed of user geometries are supported, thus the user is expected to implement a primitive/primitive intersection to filter out false positives in the callback function. The `userPtr` argument can be used to input geometry data of the scene or output results of the intersection query.

SUPPORTED PRIMITIVES

Currently, the only supported type is the user geometry type (see `RTC_GEOMETRY_TYPE_USER`).

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewBVH

NAME

rtcNewBVH - creates a **new** BVH object

SYNOPSIS

```
#include <embree3/rtcore.h>

RTC BVH rtcNewBVH(RTCDevice device);
```

DESCRIPTION

This function creates a new BVH object and returns a handle to this BVH. The BVH object is reference counted with an initial reference count of 1. The handle can be released using the `rtcReleaseBVH` API call.

The BVH object can be used to build a BVH in a user-specified format over user-specified primitives. See the documentation of the `rtcBuildBVH` call for more details.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcRetainBVH, rtcReleaseBVH, rtcBuildBVH

rtcRetainBVH

NAME

```
rtcRetainBVH - increments the BVH reference count
```

SYNOPSIS

```
#include <embree3/rtcore.h>
void rtcRetainBVH(RTCBVH bvh);
```

DESCRIPTION

BVH objects are reference counted. The `rtcRetainBVH` function increments the reference count of the passed BVH object (`bvh` argument). This function together with `rtcReleaseBVH` allows to use the internal reference counting in a C++ wrapper class to handle the ownership of the object.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

SEE ALSO

rtcNewBVH, *rtcReleaseBVH*

rtcReleaseBVH

NAME

rtcReleaseBVH - decrements the BVH reference count

SYNOPSIS

```
#include <embree3/rtcore.h>
void rtcReleaseBVH(RTCBVH bvh);
```

DESCRIPTION

BVH objects are reference counted. The `rtcReleaseBVH` function decrements the reference count of the passed BVH object (`bvh` argument). When the reference count falls to 0, the BVH gets destroyed.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

struct RTCBuildArguments rtcDefaultBuildArguments();

void* rtcBuildBVH(
    const struct RTCBuildArguments* args
);

```

DESCRIPTION

The `rtcBuildBVH` function can be used to build a BVH in a user-defined format over arbitrary primitives. All arguments to the function are provided through the `RTCBuildArguments` structure. The first member of that structure must be set to the size of the structure in bytes (`bytesSize` member) which allows future extensions of the structure. It is recommended to initialize the build arguments structure using the `rtcDefaultBuildArguments` function.

The `rtcBuildBVH` function gets passed the BVH to build (`bvh` member), the array of primitives (`primitives` member), the capacity of that array (`primitiveArrayCapacity` member), the number of primitives stored inside the array (`primitiveCount` member), callback function pointers, and a user-defined pointer (`userPtr` member) that is passed to all callback functions when invoked. The `primitives` array can be freed by the application after the BVH is built. All callback functions are typically called from multiple threads, thus their implementation must be thread-safe.

Four callback functions must be registered, which are invoked during build to create BVH nodes (`createNode` member), to set the pointers to all children (`setNodeChildren` member), to set the bounding boxes of all children (`setNodeBounds` member), and to create a leaf node (`createLeaf` member).

The function pointer to the primitive split function (`splitPrimitive` member) may be NULL, however, then no spatial splitting in high quality mode is possible. The function pointer used to report the build progress (`buildProgress` member) is optional and may also be NULL.

Further, some build settings are passed to configure the BVH build. Using the build quality settings (`buildQuality` member), one can select between a faster, low quality build which is good for dynamic scenes, and a standard quality build for static scenes. One can also specify the desired maximum branching factor of the BVH (`maxBranchingFactor` member), the maximum depth the BVH should have (`maxDepth` member), the block size for the SAH heuristic (`sahBlockSize` member), the minimum and maximum leaf size (`minLeafSize` and `maxLeafSize` member), and the estimated costs of one traversal step and one primitive intersection (`traversalCost` and `intersectionCost` members). When enabling the `RTC_BUILD_FLAG_DYNAMIC` build flags (`buildFlags` member), re-build performance for dynamic scenes is improved at the cost of higher memory requirements.

To spatially split primitives in high quality mode, the builder needs extra space at the end of the build primitive array to store splitted primitives. The total capacity of the build primitive array is passed using the `primitiveArrayCapacity` member, and should be about twice the number of primitives when using spatial splits.

The `RTCCreateNodeFunc` and `RTCCreateLeafFunc` callbacks are passed a thread local allocator object that should be used for fast allocation of nodes using the `rtcThreadLocalAlloc` function. We strongly recommend using this allocation mechanism, as alternative approaches like standard `malloc` can be over 10× slower. The allocator object passed to the create callbacks may be used only inside the current thread. Memory allocated using `rtcThreadLocalAlloc` is automatically freed when the `RTCBVH` object is deleted. If you use your own memory allocation scheme you have to free the memory yourself when the `RTCBVH` object is no longer used.

The `RTCCreateNodeFunc` callback additionally gets the number of children for this node in the range from 2 to `maxBranchingFactor` (`childCount` argument).

The `RTCSetNodeChildFunc` callback function gets a pointer to the node as input (`nodePtr` argument), an array of pointers to the children (`childPtrs` argument), and the size of this array (`childCount` argument).

The `RTCSetNodeBoundsFunc` callback function gets a pointer to the node as input (`nodePtr` argument), an array of pointers to the bounding boxes of the children (`bounds` argument), and the size of this array (`childCount` argument).

The `RTCCreateLeafFunc` callback additionally gets an array of primitives as input (`primitives` argument), and the size of this array (`primitiveCount` argument). The callback should read the `geomID` and `primID` members from the passed primitives to construct the leaf.

The `RTCSplitPrimitiveFunc` callback is invoked in high quality mode to split a primitive (`primitive` argument) at the specified position (`position` argument) and dimension (`dimension` argument). The callback should return bounds of the clipped left and right parts of the primitive (`leftBounds` and `rightBounds` arguments).

The `RTCProgressMonitorFunction` callback function is called with the estimated completion rate `n` in the range `[0, 1]`. Returning `true` from the callback lets the build continue; returning `false` cancels the build.

EXIT STATUS

On failure an error code is set that can be queried using `rtcGetDeviceError`.

RTCQuaternionDecomposition

NAME

RTCQuaternionDecomposition - structure that represents a quaternion decomposition of an affine transformation

SYNOPSIS

```

struct RTCQuaternionDecomposition
{
    float scale_x, scale_y, scale_z;
    float skew_xy, skew_xz, skew_yz;
    float shift_x, shift_y, shift_z;
    float quaternion_r, quaternion_i, quaternion_j, quaternion_k;
    float translation_x, translation_y, translation_z;
};

```

DESCRIPTION

The struct RTCQuaternionDecomposition represents an affine transformation decomposed into three parts. An upper triangular scaling/skew/shift matrix

$$S = \begin{pmatrix} scale_x & skew_{xy} & skew_{xz} & shift_x \\ 0 & scale_y & skew_{yz} & shift_y \\ 0 & 0 & scale_z & shift_z \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

a translation matrix

$$T = \begin{pmatrix} 1 & 0 & 0 & translation_x \\ 0 & 1 & 0 & translation_y \\ 0 & 0 & 1 & translation_z \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

and a rotation matrix R , represented as a quaternion

$quaternion_r + quaternion_i \mathbf{i} + quaternion_j \mathbf{j} + quaternion_k \mathbf{k}$

where $\mathbf{i}, \mathbf{j}, \mathbf{k}$ are the imaginary quaternion units. The passed quaternion will be normalized internally.

The affine transformation matrix corresponding to a RTCQuaternionDecomposition is TRS and a point $p = (p_x, p_y, p_z, 1)^T$ will be transformed as

$$p' = T R S p.$$

The functions `rtcInitQuaternionDecomposition`, `rtcQuaternionDecompositionSetQuaternion`, `rtcQuaternionDecompositionSetScale`, `rtcQuaternionDecompositionSetSkew`, `rtcQuaternionDecompositionSetShift`, and `rtcQuaternionDecompositionSetTranslation` allow to set the fields of the structure more conveniently.

EXIT STATUS

No error code is set by this function.

rtcInitQuaternionDecomposition

NAME

rtcInitQuaternionDecomposition - initializes quaternion decomposition

SYNOPSIS

```
void rtcInitQuaternionDecomposition(  
    struct RTCQuaternionDecomposition* qd  
);
```

DESCRIPTION

The `rtcInitQuaternionDecomposition` function initializes a `RTCQuaternionDecomposition` structure to represent an identity transformation.

EXIT STATUS

No error code is set by this function.

Open VKL

Open Volume Kernel Library (Open VKL) is a collection of high-performance volume computation kernels.

Introduction

Open Volume Kernel Library (Open VKL) is a collection of high-performance volume computation kernels. The target users of Open VKL are graphics application engineers who want to improve the performance of their volume rendering applications by leveraging Open VKL's performance-optimized kernels, which include volume traversal and sampling functionality for a variety of volumetric data formats.

Open VKL provides a C API, and also supports applications written with the Intel® SPMD Program Compiler (ISPC) by also providing an ISPC interface to the core volume algorithms. This makes it possible to write a renderer in ISPC that automatically vectorizes and leverages SSE, AVX, AVX2, and AVX-512 instructions. ISPC also supports runtime code selection, thus ISPC will select the best code path for your application.

Open VKL API

To access the Open VKL API you first need to include the Open VKL header. For C99 or C++:

```
#include <openvkl/openvkl.h>
```

For the Intel® Implicit SPMD Program Compiler (Intel® ISPC):

```
#include <openvkl/openvkl.isph>
```

This documentation will discuss the C99/C++ API. The ISPC version has the same functionality and flavor. Looking at the headers, the `vkltutorialISPC` example, and this documentation should be enough to figure it out.

Device initialization and shutdown

To use the API, one of the implemented backends must be loaded. Currently the only one that exists is the CPU device. To load the module that implements the CPU device:

```
vkLoadModule("cpu_device");
```

The device then needs to be instantiated:

```
VKLDevice device = vkNewDevice("cpu");
```

By default, the CPU device selects the maximum supported SIMD width (and associated ISA) for the system. Optionally, a specific width may be requested using the `cpu_4`, `cpu_8`, or `cpu_16` device names. Note that the system must support the given width (SSE4.1 for 4-wide, AVX for 8-wide, and AVX512 for 16-wide).

Once a device is created, you can call

```
void vkDeviceSetInt(VKLDevice, const char *name, int val);
void vkDeviceSetString(VKLDevice, const char *name, const char *val);
```

to set parameters on the device. The following parameters are understood by all devices:

Table 1: Parameters shared by all devices.

Type	Name	Description
int	logLevel	logging level; valid values are VKL_LOG_DEBUG, VKL_LOG_INFO, VKL_LOG_WARNING, VKL_LOG_ERROR and VKL_LOG_NONE
string	logOutput	convenience for setting where log messages go; valid values are cout, cerr and none
string	errorOutput	convenience for setting where error messages go; valid values are cout, cerr and none
int	numThreads	number of threads which Open VKL can use
int	flushDenormals	sets the Flush to Zero and Denormals are Zero mode of the MXCSR control and status register (default: 1); see Performance Recommendations section for details

Once parameters are set, the device must be committed with

```
vk1CommitDevice(device);
```

The newly committed device is then ready to use. Users may change parameters on a device after initialization. In this case the device would need to be re-committed.

All Open VKL objects are associated with a device. A device handle must be explicitly provided when creating volume and data objects, via `vk1NewVolume()` and `vk1NewData()` respectively. Other object types are automatically associated with a device via transitive dependency on a volume.

Open VKL provides vector-wide versions for several APIs. To determine the native vector width for a given device, call:

```
int width = vk1GetNativeSIMDWidth(VKLDevice device);
```

When the application is finished with an Open VKL device or shutting down, release the device via:

```
vk1ReleaseDevice(VKLDevice device);
```

Environment variables

The generic device parameters can be overridden via environment variables for easy changes to Open VKL's behavior without needing to change the application (variables are prefixed by convention with "OPENVKL_"):

Table 2: Environment variables understood by all devices.

Variable	Description
OPEN-VKL_LOG_LEVEL	logging level; valid values are debug, info, warning, error and none
OPEN-VKL_LOG_OUTPUT	convenience for setting where log messages go; valid values are cout, cerr and none
OPEN-VKL_ERROR_OUTPUT	convenience for setting where error messages go; valid values are cout, cerr and none
OPEN-VKL_THREADS	number of threads which Open VKL can use
OPEN-VKL_FLUSH_DENORMALS	sets the Flush to Zero and Denormals are Zero mode of the MXCSR control and status register (default: 1); see Performance Recommendations section for details

Note that these environment variables take precedence over values set through the `vk1DeviceSet*()` functions.

Additionally, the CPU device's default SIMD width can be overridden at run time with the `OPENVKL_CPU_DEVICE_DEFAULT_WIDTH` environment variable. Legal values are 4, 8, or 16. This setting is only applicable when the generic `cpu` device is instantiated; if a specific width is requested via the `cpu_[4,8,16]` device names then the environment variable is ignored.

Error handling and log messages

The following errors are currently used by Open VKL:

Table 3: Possible error codes, i.e., valid named constants of type `VKLError`.

Name	Description
<code>VKL_NO_ERROR</code>	no error occurred
<code>VKL_UNKNOWN_ERROR</code>	an unknown error occurred
<code>VKL_INVALID_ARGUMENT</code>	an invalid argument was specified
<code>VKL_INVALID_OPERATION</code>	the operation is not allowed for the specified object
<code>VKL_OUT_OF_MEMORY</code>	there is not enough memory to execute the command
<code>VKL_UNSUPPORTED_CPU</code>	the CPU is not supported (minimum ISA is SSE4.1)

These error codes are either directly returned by some API functions, or are recorded to be later queried by the application via

```
VKLError vklDeviceGetLastErrorCode(VKLDevice);
```

A more descriptive error message can be queried by calling

```
const char* vklDeviceGetLastErrorMsg(VKLDevice);
```

Alternatively, the application can also register a callback function of type

```
typedef void (*VKLErrorCallback)(void *, VKLError, const char* message);
```

via

```
void vklDeviceSetErrorCallback(VKLDevice, VKLErrorFunc, void *);
```

to get notified when errors occur. Applications may be interested in messages which Open VKL emits, whether for debugging or logging events. Applications can register a callback function of type

```
typedef void (*VKLLogCallback)(void *, const char* message);
```

via

```
void vklDeviceSetLogCallback(VKLDevice, VKLLogCallback, void *);
```

which Open VKL will use to emit log messages. Applications can clear either callback by passing `nullptr` instead of an actual function pointer. By default, Open VKL uses `cout` and `cerr` to emit log and error messages, respectively. The last parameter to `vklDeviceSetErrorCallback` and `vklDeviceSetLogCallback` is a user data pointer. Open VKL passes this pointer to the callback functions as the first parameter. Note that in addition to setting the above callbacks, this behavior can be changed via the device parameters and environment variables described previously.

Basic data types

Open VKL defines 3-component vectors of integer and vector types:

```
typedef struct
{
    int x, y, z;
} vkl_vec3i;

typedef struct
{
    float x, y, z;
} vkl_vec3f;
```

Vector versions of these are also defined in structure-of-array format for 4, 8, and 16 wide types.

```
typedef struct
{
    float x[WIDTH];
    float y[WIDTH];
    float z[WIDTH];
} vkl_vvec3f##WIDTH;

typedef struct
{
    float lower[WIDTH], upper[WIDTH];
} vkl_vrange1f##WIDTH;
```

1-D range and 3-D ranges are defined as ranges and boxes, with no vector versions:

```
typedef struct
{
    float lower, upper;
} vkl_range1f;

typedef struct
{
    vkl_vec3f lower, upper;
} vkl_box3f;
```

Object model

Objects in Open VKL are exposed to the APIs as handles with internal reference counting for lifetime determination. Objects are created with particular type's `vklNew...` API entry point. For example, `vklNewData` and `vklNewVolume`.

In general, modifiable parameters to objects are modified using `vklSet...` functions based on the type of the parameter being set. The parameter name is passed as a string. Below are all variants of `vklSet...`

```
void vklSetBool(VKLObject object, const char *name, int b);
void vklSetFloat(VKLObject object, const char *name, float x);
void vklSetVec3f(VKLObject object, const char *name, float x, float y, float z);
void vklSetInt(VKLObject object, const char *name, int x);
void vklSetVec3i(VKLObject object, const char *name, int x, int y, int z);
```

(continues on next page)

(continued from previous page)

```
void vk1SetData(VKLObject object, const char *name, VKLData data);
void vk1SetString(VKLObject object, const char *name, const char *s);
void vk1SetVoidPtr(VKLObject object, const char *name, void *v);
```

After parameters have been set, `vk1Commit` must be called on the object to make them take effect.

Open VKL uses reference counting to manage the lifetime of all objects. Therefore one cannot explicitly “delete” any object. Instead, one can indicate the application does not need or will not access the given object anymore by calling

```
void vk1Release(VKLObject);
```

This decreases the object’s reference count. If the count reaches 0 the object will automatically be deleted.

Managed data

Large data is passed to Open VKL via a `VKLData` handle created with `vk1NewData`:

```
VKLData vk1NewData(VKLDevice device,
                  size_t numItems,
                  VKLDataType dataType,
                  const void *source,
                  VKLDataCreationFlags dataCreationFlags,
                  size_t byteStride);
```

Data objects can be created as Open VKL owned (`dataCreationFlags = VKL_DATA_DEFAULT`), in which the library will make a copy of the data for its use, or shared (`dataCreationFlags = VKL_DATA_SHARED_BUFFER`), which will try to use the passed pointer for usage. The library is allowed to copy data when a volume is committed.

The distance between consecutive elements in `source` is given in bytes with `byteStride`. If the provided `byteStride` is zero, then it will be determined automatically as `sizeof(type)`. Open VKL owned data will be compacted into a naturally-strided array on copy, regardless of the original `byteStride`.

As with other object types, when data objects are no longer needed they should be released via `vk1Release`.

The enum type `VKLDataType` describes the different element types that can be represented in Open VKL. The types accepted vary per volume; see the volume section for specifics. Valid constants are listed in the table below.

Table 4: Valid named constants for VKLDataType.

Type/Name	Description
VKL_DEVICE	API device object reference
VKL_DATA	data reference
VKL_OBJECT	generic object reference
VKL_VOLUME	volume object reference
VKL_STRING	C-style zero-terminated character string
VKL_CHAR, VKL_VEC[234]C	8 bit signed character scalar and [234]-element vector
VKL_UCHAR, VKL_VEC[234]UC	8 bit unsigned character scalar and [234]-element vector
VKL_SHORT, VKL_VEC[234]S	16 bit unsigned integer scalar and [234]-element vector
VKL_USHORT, VKL_VEC[234]US	16 bit unsigned integer scalar and [234]-element vector
VKL_INT, VKL_VEC[234]I	32 bit signed integer scalar and [234]-element vector
VKL_UINT, VKL_VEC[234]UI	32 bit unsigned integer scalar and [234]-element vector
VKL_LONG, VKL_VEC[234]L	64 bit signed integer scalar and [234]-element vector
VKL_ULONG, VKL_VEC[234]UL	64 bit unsigned integer scalar and [234]-element vector
VKL_HALF, VKL_VEC[234]H	16 bit half precision floating-point scalar and [234]-element vector (IEEE 754 binary16)
VKL_FLOAT, VKL_VEC[234]F	32 bit single precision floating-point scalar and [234]-element vector
VKL_DOUBLE, VKL_VEC[234]D	64 bit double precision floating-point scalar and [234]-element vector
VKL_BOX[1234]I	32 bit integer box (lower + upper bounds)
VKL_BOX[1234]F	32 bit single precision floating-point box (lower + upper bounds)
VKL_LINEAR[23]F	32 bit single precision floating-point linear transform ([23] vectors)
VKL_AFFINE[23]F	32 bit single precision floating-point affine transform (linear transform plus translation)
VKL_VOID_PTR	raw memory address

Observers

Volumes and samplers in Open VKL may provide observers to communicate data back to the application. Observers may be created with

```
VKLObserver vk1NewSamplerObserver(VKLSampler sampler,
                                   const char *type);

VKLObserver vk1NewVolumeObserver(VKLVolume volume,
                                   const char *type);
```

The object passed to `vk1New*Observer` must already be committed. Valid observer type strings are defined by volume implementations (see section ‘Volume types’ below).

`vk1New*Observer` returns NULL on failure.

To access the underlying data, an observer must first be mapped using

```
const void * vklMapObserver(VKLObserver observer);
```

If this fails, the function returns NULL. `vklMapObserver` may fail on observers that are already mapped. On success, the application may query the underlying type, element size in bytes, and the number of elements in the buffer using

```
VKLDataType vklGetObserverElementType(VKLObserver observer);
size_t vklGetObserverElementSize(VKLObserver observer);
size_t vklGetObserverNumElements(VKLObserver observer);
```

On failure, these functions return `VKL_UNKNOWN` and `0`, respectively. Possible data types are defined by the volume that provides the observer, as are the semantics of the observation. See section ‘Volume types’ for details.

The pointer returned by `vklMapObserver` may be cast to the type corresponding to the value returned by `vklGetObserverElementType` to access the observation. For example, if `vklGetObserverElementType` returns `VKL_FLOAT`, then the pointer returned by `vklMapObserver` may be cast to `const float *` to access up to `vklGetObserverNumElements` consecutive values of type `float`.

Once the application has finished processing the observation, it should unmap the observer using

```
void vklUnmapObserver(VKLObserver observer);
```

so that the observer may be mapped again.

When an observer is no longer needed, it should be released using `vklRelease`.

The observer API is not thread safe, and these functions should not be called concurrently on the same object.

Volume types

Open VKL currently supports structured volumes on regular and spherical grids; unstructured volumes with tetrahedral, wedge, pyramid, and hexadheral primitive types; adaptive mesh refinement (AMR) volumes; sparse VDB volumes; and particle volumes. Volumes are created with `vklNewVolume` with a device and appropriate type string:

```
VKLVolume vklNewVolume(VKLDevice device, const char *type);
```

In addition to the usual `vklSet...()` and `vklCommit()` APIs, the volume bounding box can be queried:

```
vkl_box3f vklGetBoundingBox(VKLVolume volume);
```

The number of attributes in a volume can also be queried:

```
unsigned int vklGetNumAttributes(VKLVolume volume);
```

Finally, the value range of the volume for a given attribute can be queried:

```
vkl_range1f vklGetValueRange(VKLVolume volume, unsigned int attributeIndex);
```

Structured Volumes

Structured volumes only need to store the values of the samples, because their addresses in memory can be easily computed from a 3D position. The dimensions for all structured volume types are in units of vertices, not cells. For example, a volume with dimensions (x, y, z) will have $(x-1, y-1, z-1)$ cells in each dimension. Voxel data provided is assumed vertex-centered, so $x * y * z$ values must be provided.

Structured Regular Volumes

A common type of structured volumes are regular grids, which are created by passing a type string of "structuredRegular" to `vk1NewVolume`. The parameters understood by structured regular volumes are summarized in the table below.

Table 5: Configuration parameters for structured regular ("structuredRegular") volumes.

Type	Name	Default	Description
vec3i	dimensions		number of voxels in each dimension (x, y, z)
VKL-Data VKL-Data[]	data		VKLData object(s) of voxel data, supported types are:
			VKL_UCHAR
			VKL_SHORT
			VKL_USHORT
			VKL_HALF
			VKL_FLOAT
			VKL_DOUBLE
			Multiple attributes are supported through passing an array of VKLData objects.
vec3f	gridOrigin	(0, 0, 0)	origin of the grid in object space
vec3f	gridSpacing	(1, 1, 1)	size of the grid cells in object space
uint32	temporalFormat	VKL_TEMPORAL_FORMAT_CONSTANT	The format constant for this volume. Use VKLTemporalFormat for named constants. Structured regular volumes support VKL_TEMPORAL_FORMAT_CONSTANT, VKL_TEMPORAL_FORMAT_STRUCTURED, and VKL_TEMPORAL_FORMAT_UNSTRUCTURED.
int	temporallyStructuredNumTimesteps		For temporally structured variation, number of timesteps per voxel. Only valid if temporalFormat is VKL_TEMPORAL_FORMAT_STRUCTURED.
uint32[] uint64[]	temporallyUnstructuredIndices		For temporally unstructured variation, indices to data time series beginning per voxel. Only valid if temporalFormat is VKL_TEMPORAL_FORMAT_UNSTRUCTURED.
float[]	temporallyUnstructuredTimes		For temporally unstructured variation, time values corresponding to values in data. Only valid if temporalFormat is VKL_TEMPORAL_FORMAT_UNSTRUCTURED.
float[]	background	VKL_BACKGROUND_UNDEFINED	By default, the value that is returned when sampling an undefined region outside the volume domain.

Structured regular volumes support temporally structured and temporally unstructured temporal variation. See section ‘Temporal Variation’ for more detail.

The following additional parameters can be set both on "structuredRegular" volumes and their sampler objects. Sampler object parameters default to volume parameters.

Table 6: Configuration parameters for structured regular ("structuredRegular") volumes and their sampler objects.

Type	Name	Default	Description
int	filter	VKL_FILTER_TRILINEAR	The filter used for reconstructing the field. Use <code>VKLFilter</code> for named constants.
int	gradient-Filter	filter	The filter used for reconstructing the field during gradient computations. Use <code>VKLFilter</code> for named constants.

Reconstruction filters

Structured regular volumes support the filter types `VKL_FILTER_NEAREST`, `VKL_FILTER_TRILINEAR`, and `VKL_FILTER_TRICUBIC` for both `filter` and `gradientFilter`.

Note that when `gradientFilter` is set to `VKL_FILTER_NEAREST`, gradients are always $(0, 0, 0)$.

Structured Spherical Volumes

Structured spherical volumes are also supported, which are created by passing a type string of "structuredSpherical" to `vkNewVolume`. The grid dimensions and parameters are defined in terms of radial distance (r), inclination angle (θ), and azimuthal angle (ϕ), conforming with the ISO convention for spherical coordinate systems. The coordinate system and parameters understood by structured spherical volumes are summarized below.

Table 7: Configuration parameters for structured spherical ("structuredSpherical") volumes.

Type	Name	Default	Description
vec3i	dimensions		number of voxels in each dimension (r, θ, ϕ)
VKLData VKLData[]	data		VKLData object(s) of voxel data, supported types are: <code>VKL_UCHAR</code> <code>VKL_SHORT</code> <code>VKL_USHORT</code> <code>VKL_HALF</code> <code>VKL_FLOAT</code> <code>VKL_DOUBLE</code> Multiple attributes are supported through passing an array of VKLData objects.
vec3f	gridOrigin	$(0, 0, 0)$	origin of the grid in units of (r, θ, ϕ) ; angles in degrees
vec3f	gridSpacing	$(1, 1, 1)$	size of the grid cells in units of (r, θ, ϕ) ; angles in degrees
float[]	background	<code>VKL_BACKGROUND_UNDEFINED</code>	UNDEFINED attribute, the value that is returned when sampling an undefined region outside the volume domain.

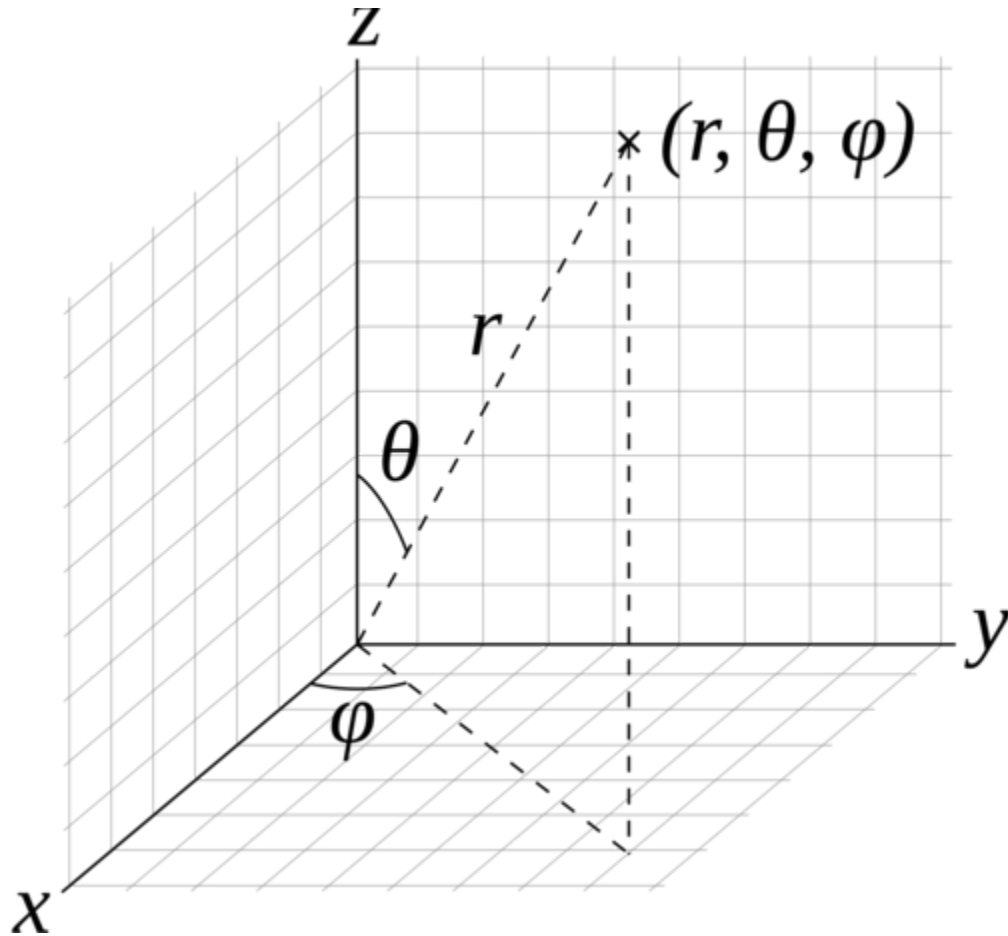

Fig. 1: Structured spherical volume coordinate system: radial distance (r), inclination angle (θ), and azimuthal angle (ϕ).

These grid parameters support flexible specification of spheres, hemispheres, spherical shells, spherical wedges, and so forth. The grid extents (computed as $[gridOrigin, gridOrigin + (dimensions - 1) * gridSpacing]$) however must be constrained such that:

- $r \geq 0$
- $0 \leq \theta \leq 180$
- $0 \leq \phi \leq 360$

The following additional parameters can be set both on "structuredSpherical" volumes and their sampler objects. Sampler object parameters default to volume parameters.

Table 8: Configuration parameters for structured spherical ("structuredSpherical") volumes and their sampler objects.

Type	Name	Default	Description
int	filter	VKL_FILTER_TRIANGLE	The filter used for reconstructing the field. Use <code>VKLFilter</code> for named constants.
int	gradient-Filter	filter	The filter used for reconstructing the field during gradient computations. Use <code>VKLFilter</code> for named constants.

Adaptive Mesh Refinement (AMR) Volumes

Open VKL currently supports block-structured (Berger-Colella) AMR volumes. Volumes are specified as a list of blocks, which exist at levels of refinement in potentially overlapping regions. Blocks exist in a tree structure, with coarser refinement level blocks containing finer blocks. The cell width is equal for all blocks at the same refinement level, though blocks at a coarser level have a larger cell width than finer levels.

There can be any number of refinement levels and any number of blocks at any level of refinement.

Blocks are defined by three parameters: their bounds, the refinement level in which they reside, and the scalar data contained within each block.

Note that cell widths are defined *per refinement level*, not per block.

AMR volumes are created by passing the type string "amr" to `vk1NewVolume`, and have the following parameters:

Table 9: Configuration parameters for AMR ("amr") volumes.

Type	Name	Default	Description
float[]	cell-Width		[data] array of each level's cell width
box3i[]	block.bounds		[data] array of each block's bounds (in voxels)
int[]	block.level		[data] array of each block's refinement level
VKL-Data[]	block.data		[data] array of each block's <code>VKLData</code> object containing the actual scalar voxel data. Currently only <code>VKL_FLOAT</code> data is supported.
vec3f	gridOrigin	(0, 0, 0)	origin of the grid in object space
vec3f	gridSpacing	(1, 1, 1)	size of the grid cells in object space
float	background	VKL_BACKGROUND_UNDEFINED	value that is returned when sampling an undefined region outside the volume domain.

Note that the `gridOrigin` and `gridSpacing` parameters act just like the structured volume equivalent, but they only modify the root (coarsest level) of refinement.

The following additional parameters can be set both on "amr" volumes and their sampler objects. Sampler object parameters default to volume parameters.

Table 10: Configuration parameters for AMR ("AMR") volumes and their sampler objects.

Type	Name	Default	Description
VKLAMRMethod	method	VKL_AMR_CURRENT	VKLAMRMethod sampling method. Supported methods are:
			VKL_AMR_CURRENT
			VKL_AMR_FINEST
			VKL_AMR_OCTANT

Open VKL's AMR implementation was designed to cover Berger-Colella [1] and Chombo [2] AMR data. The method parameter above determines the interpolation method used when sampling the volume.

- VKL_AMR_CURRENT finds the finest refinement level at that cell and interpolates through this "current" level
- VKL_AMR_FINEST will interpolate at the closest existing cell in the volume-wide finest refinement level regardless of the sample cell's level
- VKL_AMR_OCTANT interpolates through all available refinement levels at that cell. This method avoids discontinuities at refinement level boundaries at the cost of performance

Gradients are computed using finite differences, using the method defined on the sampler.

Details and more information can be found in the publication for the implementation [3].

Unstructured Volumes

Unstructured volumes can have their topology and geometry freely defined. Geometry can be composed of tetrahedral, hexahedral, wedge or pyramid cell types. The data format used is compatible with VTK and consists of multiple arrays: vertex positions and values, vertex indices, cell start indices, cell types, and cell values.

Sampled cell values can be specified either per-vertex (`vertex.data`) or per-cell (`cell.data`). If both arrays are set, `cell.data` takes precedence.

Similar to a mesh, each cell is formed by a group of indices into the vertices. For each vertex, the corresponding (by array index) data value will be used for sampling when rendering, if specified. The index order for a tetrahedron is the same as VTK_TETRA: bottom triangle counterclockwise, then the top vertex.

For hexahedral cells, each hexahedron is formed by a group of eight indices into the vertices and data values. Vertex ordering is the same as VTK_HEXAHEDRON: four bottom vertices counterclockwise, then top four counterclockwise.

For wedge cells, each wedge is formed by a group of six indices into the vertices and data values. Vertex ordering is the same as VTK_WEDGE: three bottom vertices counterclockwise, then top three counterclockwise.

For pyramid cells, each cell is formed by a group of five indices into the vertices and data values. Vertex ordering is the same as VTK_PYRAMID: four bottom vertices counterclockwise, then the top vertex.

To maintain VTK data compatibility, the `index` array may be specified with cell sizes interleaved with vertex indices in the following format: $n, id_1, \dots, id_n, m, id_1, \dots, id_m$. This alternative `index` array layout can be enabled through the `indexPrefixed` flag (in which case, the `cell.type` parameter should be omitted).

Gradients are computed using finite differences.

Unstructured volumes are created by passing the type string "unstructured" to `vk1NewVolume`, and have the following parameters:

Table 11: Configuration parameters for unstructured ("unstructured") volumes.

Type	Name	Default	Description
vec3f[]	vertex.position		[data] array of vertex positions
float[]	vertex.data		[data] array of vertex data values to be sampled
uint32[] / uint64[]	index		[data] array of indices (into the vertex array(s)) that form cells
bool	indexPrefixed	false	indicates that the <code>index</code> array is provided in a VTK-compatible format, where the indices of each cell are prefixed with the number of vertices
uint32[] / uint64[]	cell.index		[data] array of locations (into the index array), specifying the first index of each cell
float[]	cell.data		[data] array of cell data values to be sampled
uint8[]	cell.type		[data] array of cell types (VTK compatible). Supported types are:
			VKL_TETRAHEDRON
			VKL_HEXAHEDRON
			VKL_WEDGE
			VKL_PYRAMID
bool	hexIterative	false	hexahedron interpolation method, defaults to fast non-iterative version which could have rendering inaccuracies may appear if hex is not parallelepiped
bool	precomputedNormals	false	whether to accelerate by precomputing, at a cost of 12 bytes/face
float	background	VKL_BACKGROUND_UNDEFINED	The value that is returned when sampling an undefined region outside the volume domain.

VDB Volumes

VDB volumes implement a data structure that is very similar to the data structure outlined in Museth [1].

The data structure is a hierarchical regular grid at its core: Nodes are regular grids, and each grid cell may either store a constant value (this is called a tile), or child pointers.

Nodes in VDB trees are wide: Nodes on the first level have a resolution of 32^3 voxels by default, on the next level 16^3 , and on the leaf level 8^3 voxels. All nodes on a given level have the same resolution. This makes it easy to find the node containing a coordinate using shift operations (cp. [1]).

VDB leaf nodes are implicit in Open VKL: they are stored as pointers to user-provided data.

VDB volumes interpret input data as constant cells (which are then potentially filtered). This is in contrast to `structuredRegular` volumes, which have a vertex-centered interpretation.

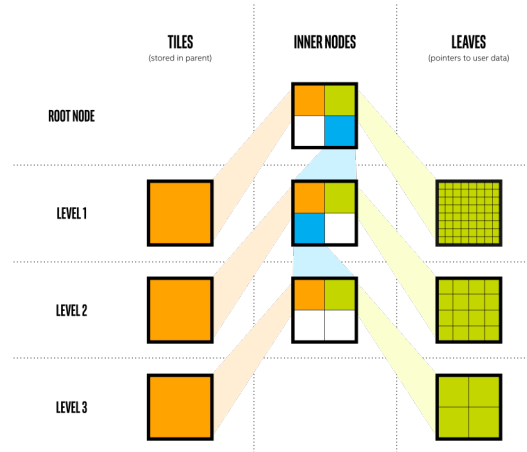

Fig. 2: Structure of "vdb" volumes in the default configuration

The VDB implementation in Open VKL follows the following goals:

- Efficient data structure traversal on vector architectures.
- Enable the use of industry-standard .vdb files created through the OpenVDB library.
- Compatibility with OpenVDB on a leaf data level, so that .vdb files may be loaded with minimal overhead.

VDB volumes are created by passing the type string "vdb" to `vk1NewVolume`, and have the following parameters:

Table 12: Configuration parameters for VDB ("vdb") volumes.

Type	Name	Default	Description
float[]	index-ToObject	1, 0, 0, 0, 1, 0, 0, 0	An array of 12 values of type float that define the transformation from index space to object space. In index space, the grid is an axis-aligned regular grid, and leaf voxels have size (1,1,1). The first 9 values are interpreted as a row-major linear transformation matrix. The last 3 values are the translation of the grid origin.
uint32[]	node.format		For each input node, the data format. Currently supported are VKL_FORMAT_TILE for tiles, and VKL_FORMAT_DENSE_ZYX for nodes that are dense regular grids.
uint32[]	node.level		For each input node, the level on which this node exists. Tiles may exist on levels [1, VKL_VDB_NUM_LEVELS-1], all other nodes may only exist on level VKL_VDB_NUM_LEVELS-1.
vec3i[]	node.origin		For each input node, the node origin index.
VKL-Data[]	node.data		For each input node, the attribute data. Single-attribute volumes may have one array provided per node, while multi-attribute volumes require an array per attribute for each node. Nodes with format VKL_FORMAT_TILE are expected to have single-entry arrays per attribute. Nodes with format VKL_FORMAT_DENSE_ZYX are expected to have arrays with <code>vk1VdbLevelNumVoxels(level[i])</code> entries per attribute. VKL_HALF and VKL_FLOAT data is currently supported; all nodes for a given attribute must be the same data type.
uint32[]	node.temporalFormat	VKL_TEMPORAL_FORMAT_CONSTANT	Temporal format for this volume. Use VKLTemporalFormat for named constants. VDB volumes support VKL_TEMPORAL_FORMAT_CONSTANT, VKL_TEMPORAL_FORMAT_STRUCTURED, and VKL_TEMPORAL_FORMAT_UNSTRUCTURED.
int[]	node.temporallyStructuredNumTimesteps		For temporally structured variation, number of timesteps per voxel. Only valid if temporalFormat is VKL_TEMPORAL_FORMAT_STRUCTURED.
VKL-Data[]	node.temporallyUnstructuredBeginning		For temporally unstructured variation, beginning per voxel. Supported data types for each node are VKL_UINT and VKL_ULONG. Only valid if temporalFormat is VKL_TEMPORAL_FORMAT_UNSTRUCTURED.
VKL-Data[]	node.temporallyUnstructuredTime		For temporally unstructured variation, time values corresponding to values in node.data. For each node, the data must be of type VKL_FLOAT. Only valid if temporalFormat is VKL_TEMPORAL_FORMAT_UNSTRUCTURED.
float[]	background	VKL_BACKGROUND_UNDEFINED	Default value that is returned when sampling an undefined region outside the volume domain.

The level, origin, format, and data parameters must have the same size, and there must be at least one valid node or `commit()` will fail.

VDB volumes support temporally structured and temporally unstructured temporal variation. See section ‘Temporal Variation’ for more detail.

The following additional parameters can be set both on vdb volumes and their sampler objects (sampler object parameters default to volume parameters).

Table 13: Configuration parameters for VDB ("vdb") volumes and their sampler objects.

Type	Name	Default	Description
int	filter	VKL_FILTER_TRILINEAR	Filter used for reconstructing the field. Use VKLFilter for named constants.
int	gradientFilter	filter	The filter used for reconstructing the field during gradient computations. Use VKLFilter for named constants.
int	maxSamplingDepth	VKL_VDB_NUM_LEVELS	Do not descend further than to this depth during sampling.

VDB volume objects support the following observers:

Table 14: Observers supported by VDB ("vdb") volumes.

Name	Buffer Type	Description
InnerNode	float[]	Return an array of bounding boxes along with value ranges, of inner nodes in the data structure. The bounding box is given in object space. For a volume with M attributes, the entries in this array are $(6+2*M)$ -tuples (minX , minY , minZ , maxX , maxY , maxZ , lower_0 , upper_0 , lower_1 , upper_1 , ...). This is in effect a low resolution representation of the volume. The InnerNode observer can be parameterized using <code>int maxDepth</code> to control the depth at which inner nodes are returned. Note that the observer will also return leaf nodes or tiles at lower levels if they exist.

VDB sampler objects support the following observers:

Table 15: Observers supported by sampler objects created on VDB ("vdb") volumes.

Name	Buffer Type	Description
LeafNodeAccess	uint32[]	This observer returns an array with as many entries as input nodes were passed. If the input node i was accessed during traversal, then the i th entry in this array has a nonzero value. This can be used for on-demand loading of leaf nodes.

Reconstruction filters

VDB volumes support the filter types `VKL_FILTER_NEAREST`, `VKL_FILTER_TRILINEAR`, and `VKL_FILTER_TRICUBIC` for both `filter` and `gradientFilter`.

Note that when `gradientFilter` is set to `VKL_FILTER_NEAREST`, gradients are always $(0, 0, 0)$.

Major differences to OpenVDB

- Open VKL implements sampling in ISPC, and can exploit wide SIMD architectures.
- VDB volumes in Open VKL are read-only once committed, and designed for rendering only. Authoring or manipulating datasets is not in the scope of this implementation.
- The only supported field types are `VKL_HALF` and `VKL_FLOAT` at this point. Other field types may be supported in the future. Note that multi-attribute volumes may be used to represent multi-component (e.g. vector) fields.
- The root level in Open VKL has a single node with resolution 64^3 (cp. [1]. OpenVDB uses a hash map, instead).
- Open VKL supports four-level vdb volumes. The resolution of each level can be configured at compile time using CMake variables.
 - `VKL_VDB_LOG_RESOLUTION_0` sets the base 2 logarithm of the root level resolution. This variable defaults to 6, which means that the root level has a resolution of $(2^6)^3 = 64^3$.
 - `VKL_VDB_LOG_RESOLUTION_1` and `VKL_VDB_LOG_RESOLUTION_2` default to 5 and 4, respectively. This matches the default Open VDB resolution for inner levels.
 - `VKL_VDB_LOG_RESOLUTION_3` set the base 2 logarithm of the leaf level resolution, and defaults to 3. Therefore, leaf nodes have a resolution of 8^3 voxels. Again, this matches the Open VDB default. The default settings lead to a domain resolution of $2^{18} = 262144^3$ voxels.

Loading OpenVDB .vdb files

Files generated with OpenVDB can be loaded easily since Open VKL vdb volumes implement the same leaf data layout. This means that OpenVDB leaf data pointers can be passed to Open VKL using shared data buffers, avoiding copy operations.

An example of this can be found in `utility/vdb/include/openvkl/utility/vdb/OpenVdbGrid.h`, where the class `OpenVdbFloatGrid` encapsulates the necessary operations. This class is also accessible through the `vk1Examples` application using the `-file` and `-field` command line arguments.

To use this example feature, compile Open VKL with `OpenVDB_ROOT` pointing to the OpenVDB prefix.

Particle Volumes

Particle volumes consist of a set of points in space. Each point has a position, a radius, and a weight typically associated with an attribute. A radial basis function defines the contribution of that particle. Currently, we use the Gaussian radial basis function,

$$\text{phi}(P) = w * \exp(-0.5 * ((P - p) / r)^2)$$

where P is the particle position, p is the sample position, r is the radius and w is the weight.

At each sample, the scalar field value is then computed as the sum of each radial basis function phi , for each particle that overlaps it. Gradients are similarly computed, based on the summed analytical contributions of each contributing particle.

The Open VKL implementation is similar to direct evaluation of samples in Reda et al.[2]. It uses an Embree-built BVH with a custom traversal, similar to the method in [1].

Particle volumes are created by passing the type string "particle" to `vk1NewVolume`, and have the following parameters:

Table 16: Configuration parameters for particle ("particle") volumes.

Type	Name	Default	Description
vec3f[]	particle.position		[data] array of particle positions
float[]	particle.radius		[data] array of particle radii
float[]	particle.weight	null	[data] (optional) array of particle weights, specifying the height of the kernel.
float	radius-Support-Factor	3.0	The multiplier of the particle radius required for support. Larger radii ensure smooth results at the cost of performance. In the Gaussian kernel, the the radius is one standard deviation (sigma), so a radiusSupportFactor of 3 corresponds to 3*sigma.
float	clamp-Max-Cumulative-Value	0	The maximum cumulative value possible, set by user. All cumulative values will be clamped to this, and further traversal (RBF summation) of particle contributions will halt when this value is reached. A value of zero or less turns this off.
bool	estimate-ValueRanges	true	Enable heuristic estimation of value ranges which are used in internal acceleration structures for interval and hit iterators, as well as for determining the volume's overall value range. When set to false, the user <i>must</i> specify clampMaxCumulativeValue, and all value ranges will be assumed [0, clampMaxCumulativeValue]. Disabling this may improve volume commit time, but will make interval and hit iteration less efficient.

Temporal Variation

Open VKL supports two types of temporal variation: temporally structured and temporally unstructured. When one of these modes is enabled, the volume can be sampled at different times. In both modes, time is assumed to vary between zero and one. This can be useful for implementing renderers with motion blur, for example.

Temporal variation is generally configured through a parameter `temporalFormat`, which accepts constants from the `VKLTemporalFormat` enum, though not all modes may be supported by all volumes. On volumes that expect multiple input nodes, the parameter is an array `node.temporalFormat`, and must provide one value per node. Multiple attributes in a voxel share the same temporal configuration. Please refer to the individual volume sections above to find out supported for each volume type.

`temporalFormat` defaults to `VKL_TEMPORAL_FORMAT_CONSTANT` for all volume types. This means that no temporal variation is present in the data.

Temporally structured variation is configured by setting `temporalFormat` to `VKL_TEMPORAL_FORMAT_STRUCTURED`. In this mode, the volume expects an additional parameter `[node.]temporallyStructuredNumTimesteps`, which specifies how many time steps are provided for all voxels, and must be at least 2. A volume, or node, with N voxels expects $N * \text{temporallyStructuredNumTimesteps}$ values for each attribute. The values are assumed evenly spaced over times $[0, 1]$: $\{0, 1/(N - 1), \dots, 1\}$

Temporally unstructured variation supports differing time step counts and sample times per voxel. For N input voxels, `temporallyUnstructuredIndices` is an array of $N + 1$ indices. Voxel i has $N_i = [\text{temporallyUnstructuredIndices}[i+1] - \text{temporallyUnstructuredIndices}[i]]$ temporal samples starting at index $\text{temporallyUnstructuredIndices}[i]$. `temporallyUnstructuredTimes` specifies the times corresponding to the sample values; the time values for each voxel must be between zero and one and strictly increasing: $t_0 < t_1 < \dots < t_N$. To return a value at sample time t , $t_0 \leq t \leq t_N$, Open VKL will interpolate linearly from the two nearest time steps. Time values outside this range are clamped to $[t_0, t_N]$.

Sampler Objects

Computing the value of a volume at an object space coordinate is done using the sampling API, and sampler objects. Sampler objects can be created using

```
VKLSampler vklNewSampler(VKLVolume volume);
```

Sampler objects may then be parametrized with traversal parameters. Available parameters are defined by volumes, and are a subset of the volume parameters. As an example, `filter` can be set on both vdb volumes and their sampler objects. The volume parameter is used as the default for sampler objects. The sampler object parameter provides an override per ray. More detail on parameters can be found in the sections on volumes. Use `vklCommit()` to commit parameters to the sampler object.

Sampling

The scalar API takes a volume and coordinate, and returns a float value. The volume's background value (by default `VKL_BACKGROUND_UNDEFINED`) is returned for probe points outside the volume. The attribute index selects the scalar attribute of interest; not all volumes support multiple attributes. The time value, which must be between 0 and 1, specifies the sampling time. For temporally constant volumes, this value has no effect.

```
float vklComputeSample(VKLSampler sampler,
                      const vkl_vec3f *objectCoordinates,
                      unsigned int attributeIndex,
                      float time);
```

Vector versions allow sampling at 4, 8, or 16 positions at once. Depending on the machine type and Open VKL device implementation, these can give greater performance. An active lane mask `valid` is passed in as an array of integers; set 0 for lanes to be ignored, -1 for active lanes. An array of time values corresponding to each object coordinate may be provided; a NULL value indicates all times are zero.

```
void vklComputeSample4(const int *valid,
                     VKLSampler sampler,
                     const vkl_vvec3f4 *objectCoordinates,
                     float *samples,
                     unsigned int attributeIndex,
                     const float *times);

void vklComputeSample8(const int *valid,
                     VKLSampler sampler,
                     const vkl_vvec3f8 *objectCoordinates,
                     float *samples,
                     unsigned int attributeIndex,
                     const float *times);
```

(continues on next page)

(continued from previous page)

```
void vklComputeSample16(const int *valid,
                       VKLSampler sampler,
                       const vkl_ivec3f16 *objectCoordinates,
                       float *samples,
                       unsigned int attributeIndex,
                       const float *times);
```

A stream version allows sampling an arbitrary number of positions at once. While the vector version requires coordinates to be provided in a structure-of-arrays layout, the stream version allows coordinates to be provided in an array-of-structures layout. Thus, the stream API can be used to avoid reformatting of data by the application. As with the vector versions, the stream API can give greater performance than the scalar API.

```
void vklComputeSampleN(VKLSampler sampler,
                      unsigned int N,
                      const vkl_vec3f *objectCoordinates,
                      float *samples,
                      unsigned int attributeIndex,
                      const float *times);
```

All of the above sampling APIs can be used, regardless of the device's native SIMD width.

Sampling Multiple Attributes

Open VKL provides additional APIs for sampling multiple scalar attributes in a single call through the `vklComputeSampleM*()` interfaces. Beyond convenience, these can give improved performance relative to the single attribute sampling APIs. As with the single attribute APIs, sampling time values may be specified; note that these are provided per object coordinate only (rather than separately per attribute).

A scalar API supports sampling `M` attributes specified by `attributeIndices` on a single object space coordinate:

```
void vklComputeSampleM(VKLSampler sampler,
                      const vkl_vec3f *objectCoordinates,
                      float *samples,
                      unsigned int M,
                      const unsigned int *attributeIndices,
                      float time);
```

Vector versions allow sampling at 4, 8, or 16 positions at once across the `M` attributes:

```
void vklComputeSampleM4(const int *valid,
                       VKLSampler sampler,
                       const vkl_vvec3f4 *objectCoordinates,
                       float *samples,
                       unsigned int M,
                       const unsigned int *attributeIndices,
                       const float *times);

void vklComputeSampleM8(const int *valid,
                       VKLSampler sampler,
                       const vkl_vvec3f8 *objectCoordinates,
                       float *samples,
                       unsigned int M,
```

(continues on next page)

(continued from previous page)

```

        const unsigned int *attributeIndices,
        const float *times);

void vklComputeSampleM16(const int *valid,
                        VKLSampler sampler,
                        const vkl_vvec3f16 *objectCoordinates,
                        float *samples,
                        unsigned int M,
                        const unsigned int *attributeIndices,
                        const float *times);

```

The $[4, 8, 16] * M$ sampled values are populated in the `samples` array in a structure-of-arrays layout, with all values for each attribute provided in sequence. That is, sample values $s_{m,n}$ for the m th attribute and n th object coordinate will be populated as

```

samples = [s_0,0,  s_0,1,  ..., s_0,N-1,
          s_1,0,  s_1,1,  ..., s_1,N-1,
          ...,
          s_M-1,0, s_M-1,1, ..., s_M-1,N-1]

```

A stream version allows sampling an arbitrary number of positions at once across the M attributes. As with single attribute stream sampling, the N coordinates are provided in an array-of-structures layout.

```

void vklComputeSampleMN(VKLSampler sampler,
                       unsigned int N,
                       const vkl_vec3f *objectCoordinates,
                       float *samples,
                       unsigned int M,
                       const unsigned int *attributeIndices,
                       const float *times);

```

The $M * N$ sampled values are populated in the `samples` array in an array-of-structures layout, with all attribute values for each coordinate provided in sequence as

```

samples = [s_0,0,  s_1,0,  ..., s_M-1,0,
          s_0,1,  s_1,1,  ..., s_M-1,1,
          ...,
          s_0,N-1, s_1,N-1, ..., s_M-1,N-1]

```

All of the above sampling APIs can be used, regardless of the device's native SIMD width.

Gradients

In a very similar API to `vklComputeSample`, `vklComputeGradient` queries the value gradient at an object space coordinate. Again, a scalar API, now returning a `vec3f` instead of a `float`. NaN values are returned for points outside the volume. The time value, which must be between 0 and 1, specifies the sampling time. For temporally constant volumes, this value has no effect.

```

vkl_vec3f vklComputeGradient(VKLSampler sampler,
                             const vkl_vec3f *objectCoordinates,
                             unsigned int attributeIndex,
                             float time);

```

Vector versions are also provided:

```
void vklComputeGradient4(const int *valid,
                        VKLSampler sampler,
                        const vkl_vvec3f4 *objectCoordinates,
                        vkl_vvec3f4 *gradients,
                        unsigned int attributeIndex,
                        const float *times);

void vklComputeGradient8(const int *valid,
                        VKLSampler sampler,
                        const vkl_vvec3f8 *objectCoordinates,
                        vkl_vvec3f8 *gradients,
                        unsigned int attributeIndex,
                        const float *times);

void vklComputeGradient16(const int *valid,
                        VKLSampler sampler,
                        const vkl_vvec3f16 *objectCoordinates,
                        vkl_vvec3f16 *gradients,
                        unsigned int attributeIndex,
                        const float *times);
```

Finally, a stream version is provided:

```
void vklComputeGradientN(VKLSampler sampler,
                        unsigned int N,
                        const vkl_vec3f *objectCoordinates,
                        vkl_vec3f *gradients,
                        unsigned int attributeIndex,
                        const float *times);
```

All of the above gradient APIs can be used, regardless of the device's native SIMD width.

Iterators

Open VKL has APIs to search for particular volume values along a ray. Queries can be for ranges of volume values (`vklIterateInterval`) or for particular values (`vklIterateHit`).

Interval iterators require a context object to define the sampler and parameters related to iteration behavior. An interval iterator context is created via

```
VKLIntervalIteratorContext vklNewIntervalIteratorContext(VKLSampler sampler);
```

The parameters understood by interval iterator contexts are defined in the table below.

Table 17: Configuration parameters for interval iterator contexts.

Type	Name	De- fault	Description
int	at- tributeIn- dex	0	Defines the volume attribute of interest.
vk_l_range1f[]	valueRanges	[- inf, inf]	Defines the value ranges of interest. Intervals not containing any of these values ranges may be skipped during iteration.
float	inter- val- Reso- lution- Hint	0.5	A value in the range [0, 1] affecting the resolution (size) of returned intervals. A value of 0 yields the lowest resolution (largest) intervals while 1 gives the highest resolution (smallest) intervals. This value is only a hint; it may not impact behavior for all volume types.

Most volume types support the `intervalResolutionHint` parameter that can impact the size of intervals returned during iteration. These include `amr`, `particle`, `structuredRegular`, `unstructured`, and `vdb` volumes. In all cases a value of 1.0 yields the highest resolution (smallest) intervals possible, while a value of 0.0 gives the lowest resolution (largest) intervals. In general, smaller intervals will have tighter bounds on value ranges, and more efficient space skipping behavior than larger intervals, which can be beneficial for some rendering methods.

For `structuredRegular`, `unstructured`, and `vdb` volumes, a value of 1.0 will enable elementary cell iteration, such that each interval spans an individual voxel / cell intersection. Note that interval iteration can be significantly slower in this case.

As with other objects, the interval iterator context must be committed before being used.

To query an interval, a `VKLIntervalIterator` of scalar or vector width must be initialized with `vkInitIntervalIterator`. Time value(s) may be provided to specify the sampling time. These values must be between 0 and 1; for the vector versions, a `NULL` value indicates all times are zero. For temporally constant volumes, the time values have no effect.

```
VKLIntervalIterator vkInitIntervalIterator(VKLIntervalIteratorContext context,
                                           const vkl_vec3f *origin,
                                           const vkl_vec3f *direction,
                                           const vkl_range1f *tRange,
                                           float time,
                                           void *buffer);

VKLIntervalIterator4 vkInitIntervalIterator4(const int *valid,
                                             VKLIntervalIteratorContext context,
                                             const vkl_vvec3f4 *origin,
                                             const vkl_vvec3f4 *direction,
                                             const vkl_vrange1f4 *tRange,
                                             const float *times,
                                             void *buffer);

VKLIntervalIterator8 vkInitIntervalIterator8(const int *valid,
                                              VKLIntervalIteratorContext context,
                                              const vkl_vvec3f8 *origin,
                                              const vkl_vvec3f8 *direction,
                                              const vkl_vrange1f8 *tRange,
                                              const float *times,
                                              void *buffer);
```

(continues on next page)

(continued from previous page)

```
VKLIntervalIterator16 vklInitIntervalIterator16(const int *valid,
                                                VKLIntervalIteratorContext context,
                                                const vkl_vvec3f16 *origin,
                                                const vkl_vvec3f16 *direction,
                                                const vkl_vrange1f16 *tRange,
                                                const float *times,
                                                void *buffer);
```

Open VKL places the iterator struct into a user-provided buffer, and the returned handle is essentially a pointer into this buffer. This means that the iterator handle must not be used after the buffer ceases to exist. Copying iterator buffers is currently not supported.

The required size, in bytes, of the buffer can be queried with

```
size_t vklGetIntervalIteratorSize(VKLIntervalIteratorContext context);

size_t vklGetIntervalIteratorSize4(VKLIntervalIteratorContext context);

size_t vklGetIntervalIteratorSize8(VKLIntervalIteratorContext context);

size_t vklGetIntervalIteratorSize16(VKLIntervalIteratorContext context);
```

The values these functions return may change depending on the parameters set on `sampler`.

Open VKL also provides a conservative maximum size over all volume types as a preprocessor definition (`VKL_MAX_INTERVAL_ITERATOR_SIZE`). For ISPC use cases, Open VKL will attempt to detect the native vector width using `TARGET_WIDTH`, which is defined in recent versions of ISPC, to provide a less conservative size.

Intervals can then be processed by calling `vklIterateInterval` as long as the returned lane masks indicates that the iterator is still within the volume:

```
int vklIterateInterval(VKLIntervalIterator iterator,
                      VKLInterval *interval);

void vklIterateInterval4(const int *valid,
                        VKLIntervalIterator4 iterator,
                        VKLInterval4 *interval,
                        int *result);

void vklIterateInterval8(const int *valid,
                        VKLIntervalIterator8 iterator,
                        VKLInterval8 *interval,
                        int *result);

void vklIterateInterval16(const int *valid,
                          VKLIntervalIterator16 iterator,
                          VKLInterval16 *interval,
                          int *result);
```

The intervals returned have a t-value range, a value range, and a `nominalDeltaT` which is approximately the step size (in units of ray direction) that should be used to walk through the interval, if desired. The number and length of intervals returned is volume type implementation dependent. There is currently no way of requesting a particular splitting.

```

typedef struct
{
    vkl_range1f tRange;
    vkl_range1f valueRange;
    float nominalDeltaT;
} VKLInterval;

typedef struct
{
    vkl_vrange1f4 tRange;
    vkl_vrange1f4 valueRange;
    float nominalDeltaT[4];
} VKLInterval4;

typedef struct
{
    vkl_vrange1f8 tRange;
    vkl_vrange1f8 valueRange;
    float nominalDeltaT[8];
} VKLInterval8;

typedef struct
{
    vkl_vrange1f16 tRange;
    vkl_vrange1f16 valueRange;
    float nominalDeltaT[16];
} VKLInterval16;

```

Querying for particular values is done using a `VKLHitIterator` in much the same fashion. This API could be used, for example, to find isosurfaces. As with interval iterators, time value(s) may be provided to specify the sampling time. These values must be between 0 and 1; for the vector versions, a NULL value indicates all times are zero. For temporally constant volumes, the time values have no effect.

Hit iterators similarly require a context object to define the sampler and other iteration parameters. A hit iterator context is created via

```
VKLHitIteratorContext vklNewHitIteratorContext(VKLSampler sampler);
```

The parameters understood by hit iterator contexts are defined in the table below.

Table 18: Configuration parameters for hit iterator contexts.

Type	Name	Default	Description
int	attributeIndex	0	Defines the volume attribute of interest.
float[]	values		Defines the value(s) of interest.

The hit iterator context must be committed before being used.

Again, a user allocated buffer must be provided, and a `VKLHitIterator` of the desired width must be initialized:

```

VKLHitIterator vklInitHitIterator(VKLHitIteratorContext context,
                                const vkl_vec3f *origin,
                                const vkl_vec3f *direction,
                                const vkl_range1f *tRange,

```

(continues on next page)

(continued from previous page)

```

        float time,
        void *buffer);

VKLHitIterator4 vklInitHitIterator4(const int *valid,
                                   VKLHitIteratorContext context,
                                   const vkl_vvec3f4 *origin,
                                   const vkl_vvec3f4 *direction,
                                   const vkl_vrange1f4 *tRange,
                                   const float *times,
                                   void *buffer);

VKLHitIterator8 vklInitHitIterator8(const int *valid,
                                   VKLHitIteratorContext context,
                                   const vkl_vvec3f8 *origin,
                                   const vkl_vvec3f8 *direction,
                                   const vkl_vrange1f8 *tRange,
                                   const float *times,
                                   void *buffer);

VKLHitIterator16 vklInitHitIterator16(const int *valid,
                                       VKLHitIteratorContext context,
                                       const vkl_vvec3f16 *origin,
                                       const vkl_vvec3f16 *direction,
                                       const vkl_vrange1f16 *tRange,
                                       const float *times,
                                       void *buffer);

```

Buffer size can be queried with

```

size_t vklGetHitIteratorSize(VKLHitIteratorContext context);

size_t vklGetHitIteratorSize4(VKLHitIteratorContext context);

size_t vklGetHitIteratorSize8(VKLHitIteratorContext context);

size_t vklGetHitIteratorSize16(VKLHitIteratorContext context);

```

Open VKL also provides the macro `VKL_MAX_HIT_ITERATOR_SIZE` as a conservative estimate.

Hits are then queried by looping a call to `vklIterateHit` as long as the returned lane mask indicates that the iterator is still within the volume.

```

int vklIterateHit(VKLHitIterator iterator, VKLHit *hit);

void vklIterateHit4(const int *valid,
                   VKLHitIterator4 iterator,
                   VKLHit4 *hit,
                   int *result);

void vklIterateHit8(const int *valid,
                   VKLHitIterator8 iterator,
                   VKLHit8 *hit,
                   int *result);

```

(continues on next page)

(continued from previous page)

```
void vklIterateHit16(const int *valid,
                   VKLHitIterator16 iterator,
                   VKLHit16 *hit,
                   int *result);
```

Returned hits consist of a t-value, a volume value (equal to one of the requested values specified in the context), and an (object space) epsilon value estimating the error of the intersection:

```
typedef struct
{
    float t;
    float sample;
    float epsilon;
} VKLHit;

typedef struct
{
    float t[4];
    float sample[4];
    float epsilon[4];
} VKLHit4;

typedef struct
{
    float t[8];
    float sample[8];
    float epsilon[8];
} VKLHit8;

typedef struct
{
    float t[16];
    float sample[16];
    float epsilon[16];
} VKLHit16;
```

For both interval and hit iterators, only the vector-wide API for the native SIMD width (determined via `vklGetNativeSIMDWidth`) can be called. The scalar versions are always valid. This restriction will likely be lifted in the future.

Performance Recommendations

MXCSR control and status register

It is strongly recommended to have the Flush to Zero and Denormals are Zero mode of the MXCSR control and status register enabled for each thread before calling the sampling, gradient, or interval API functions. Otherwise, under some circumstances special handling of denormalized floating point numbers can significantly reduce application and Open VKL performance. The device parameter `flushDenormals` or environment variable `OPENVKL_FLUSH_DENORMALS` can be used to toggle this mode; by default it is enabled. Alternatively, when using Open VKL together with the Intel® Threading Building Blocks, it is sufficient to execute the following code at the beginning of the application main thread (before the creation of the `tbb::task_scheduler_init` object):

```
#include <xmmintrin.h>
#include <pmmmintrin.h>
...
_MM_SET_FLUSH_ZERO_MODE(_MM_FLUSH_ZERO_ON);
_MM_SET_DENORMALS_ZERO_MODE(_MM_DENORMALS_ZERO_ON);
```

If using a different tasking system, make sure each thread calling into Open VKL has the proper mode set.

Iterator Allocation

`vkInitIntervalIterator` and `vkInitHitIterator` expect a user allocated buffer. While this buffer can be allocated by any means, we expect iterators to be used in inner loops and advise against heap allocation in that case. Applications may provide high performance memory pools, but as a preferred alternative we recommend stack allocated buffers.

In C99, variable length arrays provide an easy way to achieve this:

```
const size_t bufferSize = vkGetIntervalIteratorSize(sampler);
char buffer[bufferSize];
```

Note that the call to `vkGetIntervalIteratorSize` or `vkGetHitIteratorSize` should not appear in an inner loop as it is relatively costly. The return value depends on the volume type, target architecture, and parameters to `sampler`.

In C++, variable length arrays are not part of the standard. Here, users may rely on `alloca` and similar functions:

```
#include <alloca.h>
const size_t bufferSize = vkGetIntervalIteratorSize(sampler);
void *buffer = alloca(bufferSize);
```

Similarly for ISPC, variable length arrays are not supported, but `alloca` may be used:

```
const uniform size_t bufferSize = vkGetIntervalIteratorSizeV(sampler);
void *uniform buffer = alloca(bufferSize);
```

Users should understand the implications of `alloca`. In particular, `alloca` does check available stack space and may result in stack overflow. `buffer` also becomes invalid at the end of the scope. As one consequence, it cannot be returned from a function. On Windows, `_malloca` is a safer option that performs additional error checking, but requires the use of `_freea`.

Applications may instead rely on the `VKL_MAX_INTERVAL_ITERATOR_SIZE` and `VKL_MAX_HIT_ITERATOR_SIZE` macros. For example, in ISPC:

```
uniform unsigned int8 buffer[VKL_MAX_INTERVAL_ITERATOR_SIZE];
```

These values are majorants over all devices and volume types. Note that Open VKL attempts to detect the target SIMD width using `TARGET_WIDTH`, returning smaller buffer sizes for narrow architectures. However, Open VKL may fall back to the largest buffer size over all targets.

Multi-attribute Volume Data Layout

Open VKL provides flexible managed data APIs that allow applications to specify input data in various formats and layouts. When shared buffers are used (`dataCreationFlags = VKL_DATA_SHARED_BUFFER`), Open VKL will use the application-owned memory directly, respecting the input data layout. Shared buffers therefore allow applications to strategically select the best layout for multi-attribute volume data and expected sampling behavior.

For volume attributes that are sampled individually (e.g. using `vkComputeSample[4,8,16,N]()`), it is recommended to use a structure-of-arrays layout. That is, each attribute's data should be compact in contiguous memory. This can be accomplished by simply using Open VKL owned data objects (`dataCreationFlags = VKL_DATA_DEFAULT`), or by using a natural `byteStride` for shared buffers.

For volume attributes that are sampled simultaneously (e.g. using `vkComputeSampleM[4,8,16,N]()`), it is recommended to use an array-of-structures layout. That is, data for these attributes should be provided per voxel in a contiguous layout. This is accomplished using shared buffers for each attribute with appropriate byte strides. For example, for a three attribute structured volume representing a velocity field, the data can be provided as:

```
// used in Open VKL shared buffers, so must not be freed by application
std::vector<vkl_vec3f> velocities(numVoxels);

for (auto &v : velocities) {
    v.x = ...;
    v.y = ...;
    v.z = ...;
}

std::vector<VKLData> attributes;

attributes.push_back(vklNewData(device,
                               velocities.size(),
                               VKL_FLOAT,
                               &velocities[0].x,
                               VKL_DATA_SHARED_BUFFER,
                               sizeof(vkl_vec3f)));

attributes.push_back(vklNewData(device,
                               velocities.size(),
                               VKL_FLOAT,
                               &velocities[0].y,
                               VKL_DATA_SHARED_BUFFER,
                               sizeof(vkl_vec3f)));

attributes.push_back(vklNewData(device,
                               velocities.size(),
                               VKL_FLOAT,
                               &velocities[0].z,
                               VKL_DATA_SHARED_BUFFER,
                               sizeof(vkl_vec3f)));

VKLData attributesData =
    vklNewData(device, attributes.size(), VKL_DATA, attributes.data());

for (auto &attribute : attributes)
    vklRelease(attribute);
```

(continues on next page)

(continued from previous page)

```
VkLVolume volume = vkLNewVolume(device, "structuredRegular");  
vkLSetData(volume, "data", attributesData);  
vkLRelease(attributesData);  
  
// set other volume parameters...  
  
vkLCommit(volume);
```

These are general recommendations for common scenarios; it is still recommended to evaluate performance of different volume data layouts for your application's particular use case.

Open Image Denoise

Open Image Denoise is an open, high-quality, efficient, and easy-to-use denoising library that allows one to significantly reduce rendering times in ray tracing based rendering applications.

Introduction

Open Image Denoise is an open, high-quality, efficient, and easy-to-use denoising library that allows one to significantly reduce rendering times in ray tracing based rendering applications. It filters out the Monte Carlo noise inherent to stochastic ray tracing methods like path tracing, reducing the amount of necessary samples per pixel by even multiple orders of magnitude (depending on the desired closeness to the ground truth). A simple but flexible C/C++ API ensures that the library can be easily integrated into most existing or new rendering solutions.

At the heart of the Open Image Denoise library is a collection of efficient deep learning based denoising filters, which were trained to handle a wide range of samples per pixel (spp), from 1 spp to almost fully converged. Thus it is suitable for both preview and final-frame rendering. The filters can denoise images either using only the noisy color (beauty) buffer, or, to preserve as much detail as possible, can optionally utilize auxiliary feature buffers as well (e.g. albedo, normal). Such buffers are supported by most renderers as arbitrary output variables (AOVs) or can be usually implemented with little effort.

Although the library ships with a set of pre-trained filter models, it is not mandatory to use these. To optimize a filter for a specific renderer, sample count, content type, scene, etc., it is possible to train the model using the included training toolkit and user-provided image datasets.

Open Image Denoise API

Open Image Denoise provides a C99 API (also compatible with C++) and a C++11 wrapper API as well. For simplicity, this document mostly refers to the C99 version of the API.

The API is designed in an object-oriented manner, e.g. it contains device objects (`OIDNDevice` type), buffer objects (`OIDNBuffer` type), and filter objects (`OIDNFilter` type). All objects are reference-counted, and handles can be released by calling the appropriate release function (e.g. `oidnReleaseDevice`) or retained by incrementing the reference count (e.g. `oidnRetainDevice`).

An important aspect of objects is that setting their parameters do not have an immediate effect (with a few exceptions). Instead, objects with updated parameters are in an unusable state until the parameters get explicitly committed to a given object. The commit semantic allows for batching up multiple small changes, and specifies exactly when changes to objects will occur.

All API calls are thread-safe, but operations that use the same device will be serialized, so the amount of API calls from different threads should be minimized.

Examples

To have a quick overview of the C99 and C++11 APIs, see the following simple example code snippets.

Basic denoising (C99 API)

```
#include <OpenImageDenoise/oidn.h>
...
// Create an Intel Open Image Denoise device
OIDNDevice device = oidnNewDevice(OIDN_DEVICE_TYPE_DEFAULT);
oidnCommitDevice(device);

// Create a filter for denoising a beauty (color) image using optional auxiliary images.
↳too
OIDNFilter filter = oidnNewFilter(device, "RT"); // generic ray tracing filter
oidnSetSharedFilterImage(filter, "color", colorPtr,
    OIDN_FORMAT_FLOAT3, width, height, 0, 0, 0); // beauty
oidnSetSharedFilterImage(filter, "albedo", albedoPtr,
    OIDN_FORMAT_FLOAT3, width, height, 0, 0, 0); // auxiliary
oidnSetSharedFilterImage(filter, "normal", normalPtr,
    OIDN_FORMAT_FLOAT3, width, height, 0, 0, 0); // auxiliary
oidnSetSharedFilterImage(filter, "output", outputPtr,
    OIDN_FORMAT_FLOAT3, width, height, 0, 0, 0); // denoised beauty
oidnSetFilter1b(filter, "hdr", true); // beauty image is HDR
oidnCommitFilter(filter);

// Filter the image
oidnExecuteFilter(filter);

// Check for errors
const char* errorMessage;
if (oidnGetDeviceError(device, &errorMessage) != OIDN_ERROR_NONE)
    printf("Error: %s\n", errorMessage);

// Cleanup
oidnReleaseFilter(filter);
oidnReleaseDevice(device);
```

Basic denoising (C++11 API)

```
#include <OpenImageDenoise/oidn.hpp>
...
// Create an Intel Open Image Denoise device
oidn::DeviceRef device = oidn::newDevice();
device.commit();

// Create a filter for denoising a beauty (color) image using optional auxiliary images.
↳too
oidn::FilterRef filter = device.newFilter("RT"); // generic ray tracing filter
filter.setImage("color", colorPtr, oidn::Format::Float3, width, height); // beauty
filter.setImage("albedo", albedoPtr, oidn::Format::Float3, width, height); // auxiliary
filter.setImage("normal", normalPtr, oidn::Format::Float3, width, height); // auxiliary
filter.setImage("output", outputPtr, oidn::Format::Float3, width, height); // denoised.
↳beauty
filter.set("hdr", true); // beauty image is HDR
filter.commit();

// Filter the image
filter.execute();

// Check for errors
const char* errorMessage;
if (device.getError(errorMessage) != oidn::Error::None)
    std::cout << "Error: " << errorMessage << std::endl;
```

Denoising with prefiltering (C++11 API)

```
// Create a filter for denoising a beauty (color) image using prefiltered auxiliary.
↳images too
oidn::FilterRef filter = device.newFilter("RT"); // generic ray tracing filter
filter.setImage("color", colorPtr, oidn::Format::Float3, width, height); // beauty
filter.setImage("albedo", albedoPtr, oidn::Format::Float3, width, height); // auxiliary
filter.setImage("normal", normalPtr, oidn::Format::Float3, width, height); // auxiliary
filter.setImage("output", outputPtr, oidn::Format::Float3, width, height); // denoised.
↳beauty
filter.set("hdr", true); // beauty image is HDR
filter.set("cleanAux", true); // auxiliary images will be prefiltered
filter.commit();

// Create a separate filter for denoising an auxiliary albedo image (in-place)
oidn::FilterRef albedoFilter = device.newFilter("RT"); // same filter type as for beauty
albedoFilter.setImage("albedo", albedoPtr, oidn::Format::Float3, width, height);
albedoFilter.setImage("output", albedoPtr, oidn::Format::Float3, width, height);
albedoFilter.commit();

// Create a separate filter for denoising an auxiliary normal image (in-place)
oidn::FilterRef normalFilter = device.newFilter("RT"); // same filter type as for beauty
normalFilter.setImage("normal", normalPtr, oidn::Format::Float3, width, height);
normalFilter.setImage("output", normalPtr, oidn::Format::Float3, width, height);
```

(continues on next page)

(continued from previous page)

```
normalFilter.commit();

// Prefilter the auxiliary images
albedoFilter.execute();
normalFilter.execute();

// Filter the beauty image
filter.execute();
```

Device

Intel Open Image Denoise supports a device concept, which allows different components of the application to use the Open Image Denoise API without interfering with each other. An application first needs to create a device with

```
OIDNDevice oidnNewDevice(OIDNDeviceType type);
```

where the type enumeration maps to a specific device implementation, which can be one of the following:

Table 19: Supported device types, i.e., valid constants of type `OIDNDeviceType`.

Name	Description
<code>OIDN_DEVICE_TYPE_DEFAULT</code>	select the approximately fastest device
<code>OIDN_DEVICE_TYPE_CPU</code>	CPU device (requires SSE4.1 support or Apple Silicon)

Once a device is created, you can call

```
void oidnSetDeviceIb(OIDNDevice device, const char* name, bool value);
void oidnSetDeviceIi(OIDNDevice device, const char* name, int value);
bool oidnGetDeviceIb(OIDNDevice device, const char* name);
int oidnGetDeviceIi(OIDNDevice device, const char* name);
```

to set and get parameter values on the device. Note that some parameters are constants, thus trying to set them is an error. See the tables below for the parameters supported by devices.

Table 20: Parameters supported by all devices.

Type	Name	De- fault	Description
const int	version		combined version number (major.minor.patch) with two decimal digits per component
const int	versionMajor		major version number
const int	versionMinor		minor version number
const int	versionPatch		patch version number
int	verbose		0 verbosity level of the console output between 0–4; when set to 0, no output is printed, when set to a higher level more output is printed

Table 21: Additional parameters supported only by CPU devices.

Type	Name	De- fault	Description
int	numThreads	0	maximum number of threads which the library should use; 0 will set it automatically to get the best performance
bool	setAffinity	true	enables thread affinization (pinning software threads to hardware threads) if it is necessary for achieving optimal performance

Note that the CPU device heavily relies on setting the thread affinities to achieve optimal performance, so it is highly recommended to leave this option enabled. However, this may interfere with the application if that also sets the thread affinities, potentially causing performance degradation. In such cases, the recommended solution is to either disable setting the affinities in the application or in Intel Open Image Denoise, or to always set/reset the affinities before/after each parallel region in the application (e.g., if using TBB, with `tbb::task_arena` and `tbb::task_scheduler_observer`).

Once parameters are set on the created device, the device must be committed with

```
void oidnCommitDevice(OIDNDevice device);
```

This device can then be used to construct further objects, such as buffers and filters. Note that a device can be committed only once during its lifetime. Before the application exits, it should release all devices by invoking

```
void oidnReleaseDevice(OIDNDevice device);
```

Note that Intel Open Image Denoise uses reference counting for all object types, so this function decreases the reference count of the device, and if the count reaches 0 the device will automatically get deleted. It is also possible to increase the reference count by calling

```
void oidnRetainDevice(OIDNDevice device);
```

An application typically creates only a single device. If required differently, it should only use a small number of devices at any given time.

Error Handling

Each user thread has its own error code per device. If an error occurs when calling an API function, this error code is set to the occurred error if it stores no previous error. The currently stored error can be queried by the application via

```
OIDNError oidnGetDeviceError(OIDNDevice device, const char** outMessage);
```

where `outMessage` can be a pointer to a C string which will be set to a more descriptive error message, or it can be NULL. This function also clears the error code, which assures that the returned error code is always the first error occurred since the last invocation of `oidnGetDeviceError` on the current thread. Note that the optionally returned error message string is valid only until the next invocation of the function.

Alternatively, the application can also register a callback function of type

```
typedef void (*OIDNErrorFunction)(void* userPtr, OIDNError code, const char* message);
```

via

```
void oidnSetDeviceErrorFunction(OIDNDevice device, OIDNErrorFunction func, void* userPtr);
```

to get notified when errors occur. Only a single callback function can be registered per device, and further invocations overwrite the previously set callback function, which do *not* require also calling the `oidnCommitDevice` function. Passing NULL as function pointer disables the registered callback function. When the registered callback function is invoked, it gets passed the user-defined payload (`userPtr` argument as specified at registration time), the error code (code argument) of the occurred error, as well as a string (`message` argument) that further describes the error. The error code is always set even if an error callback function is registered. It is recommended to always set a error callback function, to detect all errors.

When the device construction fails, `oidnNewDevice` returns NULL as device. To detect the error code of a such failed device construction, pass NULL as device to the `oidnGetDeviceError` function. For all other invocations of `oidnGetDeviceError`, a proper device handle must be specified.

The following errors are currently used by Intel Open Image Denoise:

Table 22: Possible error codes, i.e., valid constants of type `OIDNError`.

Name	Description
<code>OIDN_ERROR_NONE</code>	no error occurred
<code>OIDN_ERROR_UNKNOWN</code>	an unknown error occurred
<code>OIDN_ERROR_INVALID_ARGUMENT</code>	an invalid argument was specified
<code>OIDN_ERROR_INVALID_OPERATION</code>	the operation is not allowed
<code>OIDN_ERROR_OUT_OF_MEMORY</code>	not enough memory to execute the operation
<code>OIDN_ERROR_UNSUPPORTED_HARDWARE</code>	the hardware (e.g., CPU) is not supported
<code>OIDN_ERROR_CANCELLED</code>	the operation was cancelled by the user

Buffer

Large data like images can be passed to Intel Open Image Denoise either via pointers to memory allocated and managed by the user (this is the recommended, often easier and more efficient approach, if supported by the device) or by creating buffer objects (supported by all devices). To create a new data buffer with memory allocated and owned by the device, holding `byteSize` number of bytes, use

```
OIDNBuffer oidnNewBuffer(OIDNDevice device, size_t byteSize);
```

The created buffer is bound to the specified device (`device` argument). The specified number of bytes are allocated at buffer construction time and deallocated when the buffer is destroyed.

It is also possible to create a “shared” data buffer with memory allocated and managed by the user with

```
OIDNBuffer oidnNewSharedBuffer(OIDNDevice device, void* ptr, size_t byteSize);
```

where `ptr` points to the user-managed memory and `byteSize` is its size in bytes. At buffer construction time no buffer data is allocated, but the buffer data provided by the user is used. The buffer data must remain valid for as long as the buffer may be used, and the user is responsible to free the buffer data when no longer required.

Similar to device objects, buffer objects are also reference-counted and can be retained and released by calling the following functions:

```
void oidnRetainBuffer(OIDNBuffer buffer);
void oidnReleaseBuffer(OIDNBuffer buffer);
```

The size of the buffer in bytes can be queried using

```
size_t oidnGetBufferSize(OIDNBuffer buffer);
```

Accessing the data stored in a buffer object is possible by mapping it into the address space of the application using

```
void* oidnMapBuffer(OIDNBuffer buffer, OIDNAccess access, size_t byteOffset, size_t
↳byteSize)
```

where `access` is the desired access mode of the mapped memory, `byteOffset` is the offset to the beginning of the mapped memory region in bytes, and `byteSize` is the number of bytes to map. The function returns a pointer to the mapped buffer data. If the specified `byteSize` is 0, the maximum available amount of memory will be mapped. The `access` argument must be one of the access modes in the following table:

Table 23: Access modes for memory regions mapped with `oidnMapBuffer`, i.e., valid constants of type `OIDNAccess`.

Name	Description
<code>OIDN_ACCESS_READ</code>	read-only access
<code>OIDN_ACCESS_WRITE</code>	write-only access
<code>OIDN_ACCESS_READ_WRITE</code>	read and write access
<code>OIDN_ACCESS_WRITE_DISCARD</code>	write-only access but the previous contents will be discarded

After accessing the mapped data in the buffer, the memory region must be unmapped with

```
void oidnUnmapBuffer(OIDNBuffer buffer, void* mappedPtr);
```

where `mappedPtr` must be a pointer returned by a call to `oidnMapBuffer` for the specified buffer. Any change to the mapped data is guaranteed to take effect only after unmapping the memory region.

It is also possible to get a pointer directly to the buffer data but this might be valid only on the device the buffer was created on:

```
void* oidnGetBufferData(OIDNBuffer buffer);
```

Data Format

Buffers store opaque data and thus have no information about the type and format of the data. Other objects, e.g. filters, typically require specifying the format of the data stored in buffers or shared via pointers. This can be done using the `OIDNFormat` enumeration type:

Table 24: Supported data formats, i.e., valid constants of type `OIDNFormat`.

Name	Description
<code>OIDN_FORMAT_UNDEFINED</code>	undefined format
<code>OIDN_FORMAT_FLOAT</code>	32-bit floating-point scalar
<code>OIDN_FORMAT_FLOAT [234]</code>	32-bit floating-point [234]-element vector
<code>OIDN_FORMAT_HALF</code>	16-bit floating-point scalar
<code>OIDN_FORMAT_HALF [234]</code>	16-bit floating-point [234]-element vector

Filter

Filters are the main objects in Intel Open Image Denoise that are responsible for the actual denoising. The library ships with a collection of filters which are optimized for different types of images and use cases. To create a filter object, call

```
OIDNFilter oidnNewFilter(OIDNDevice device, const char* type);
```

where `type` is the name of the filter type to create. The supported filter types are documented later in this section. Once created, filter objects can be retained and released with

```
void oidnRetainFilter(OIDNFilter filter);
void oidnReleaseFilter(OIDNFilter filter);
```

After creating a filter, it needs to be set up by specifying the input and output images, and potentially setting other parameter values as well.

To bind images to the filter, you can use one of the following functions:

```
void oidnSetFilterImage(OIDNFilter filter, const char* name,
                       OIDNBuffer buffer, OIDNFormat format,
                       size_t width, size_t height,
                       size_t byteOffset,
                       size_t bytePixelStride, size_t byteRowStride);

void oidnSetSharedFilterImage(OIDNFilter filter, const char* name,
                              void* ptr, OIDNFormat format,
                              size_t width, size_t height,
                              size_t byteOffset,
                              size_t bytePixelStride, size_t byteRowStride);
```

It is possible to specify either a data buffer object (`buffer` argument) with the `oidnSetFilterImage` function, or directly a pointer to shared user-managed data (`ptr` argument) with the `oidnSetSharedFilterImage` function.

In both cases, you must also specify the name of the image parameter to set (`name` argument, e.g. "color", "output"), the pixel format (`format` argument), the width and height of the image in number of pixels (`width` and `height` arguments), the starting offset of the image data (`byteOffset` argument), the pixel stride (`bytePixelStride` argument) and the row stride (`byteRowStride` argument), in number of bytes.

The row stride must be an integer multiple of the pixel stride. If the pixels and/or rows are stored contiguously (tightly packed without any gaps), you can set `bytePixelStride` and/or `byteRowStride` to 0 to let the library compute the actual strides automatically, as a convenience.

Images support only the `OIDN_FORMAT_FLOAT3` and `OIDN_FORMAT_HALF3` pixel formats. Custom image layouts with extra channels (e.g. alpha channel) or other data are supported as well by specifying a non-zero pixel stride. This way, expensive image layout conversion and copying can be avoided but the extra data will be ignored by the filter.

To unbind a previously set image from the filter, call

```
void oidnRemoveFilterImage(OIDNFilter filter, const char* name);
```

Some special data used by filters are opaque/untyped (e.g. trained model weights blobs), which can be specified with the `oidnSetSharedFilterData` function:

```
void oidnSetSharedFilterData(OIDNFilter filter, const char* name,
                             void* ptr, size_t byteSize);
```

Modifying the contents of an opaque data parameter after binding it to a filter is allowed but the filter needs to be notified that the data has been updated by calling

```
void oidnUpdateFilterData(OIDNFilter filter, const char* name);
```

Unbinding opaque data from the filter can be performed with

```
void oidnRemoveFilterData(OIDNFilter filter, const char* name);
```

Filters may have parameters other than buffers as well, which you can set and get using the following functions:

```
void oidnSetFilter1b(OIDNFilter filter, const char* name, bool value);
void oidnSetFilter1i(OIDNFilter filter, const char* name, int value);
void oidnSetFilter1f(OIDNFilter filter, const char* name, float value);
bool oidnGetFilter1b(OIDNFilter filter, const char* name);
int oidnGetFilter1i(OIDNFilter filter, const char* name);
float oidnGetFilter1f(OIDNFilter filter, const char* name);
```

Filters support a progress monitor callback mechanism that can be used to report progress of filter operations and to cancel them as well. Calling `oidnSetFilterProgressMonitorFunction` registers a progress monitor callback function (`func` argument) with payload (`userPtr` argument) for the specified filter (`filter` argument):

```
typedef bool (*OIDNProgressMonitorFunction)(void* userPtr, double n);
void oidnSetFilterProgressMonitorFunction(OIDNFilter filter,
                                         OIDNProgressMonitorFunction func,
                                         void* userPtr);
```

Only a single callback function can be registered per filter, and further invocations overwrite the previously set callback function. Passing NULL as function pointer disables the registered callback function. Once registered, Intel Open Image Denoise will invoke the callback function multiple times during filter operations, by passing the payload as set at registration time (`userPtr` argument), and a double in the range [0, 1] which estimates the progress of the operation (`n` argument). When returning `true` from the callback function, Intel Open Image Denoise will continue the filter operation normally. When returning `false`, the library will cancel the filter operation with the `OIDN_ERROR_CANCELLED` error code.

After setting all necessary parameters for the filter, the changes must be committed by calling

```
void oidnCommitFilter(OIDNFilter filter);
```

The parameters can be updated after committing the filter, but it must be re-committed for any new changes to take effect. Committing major changes to the filter (e.g. setting new image parameters, changing the image resolution) can be expensive, and thus should not be done frequently (e.g. per frame).

Finally, an image can be filtered by executing the filter with

```
void oidnExecuteFilter(OIDNFilter filter);
```

which will read the input image data from the specified buffers and produce the denoised output image.

In the following we describe the different filters that are currently implemented in Intel Open Image Denoise.

RT

The RT (ray tracing) filter is a generic ray tracing denoising filter which is suitable for denoising images rendered with Monte Carlo ray tracing methods like unidirectional and bidirectional path tracing. It supports depth of field and motion blur as well, but it is *not* temporally stable. The filter is based on a convolutional neural network (CNN), and it aims to provide a good balance between denoising performance and quality. The filter comes with a set of pre-trained CNN models that work well with a wide range of ray tracing based renderers and noise levels.

[Example noisy beauty image rendered using unidirectional path tracing (4 samples per pixel). *Scene by Evermotion.*][imgMazdaColor]

[Example output beauty image denoised using prefiltered auxiliary feature images (albedo and normal) too.][imgMazdaDenoised]

For denoising *beauty* images, it accepts either a low dynamic range (LDR) or high dynamic range (HDR) image (color) as the main input image. In addition to this, it also accepts *auxiliary feature* images, `albedo` and `normal`, which are optional inputs that usually improve the denoising quality significantly, preserving more details.

It is possible to denoise auxiliary images as well, in which case only the respective auxiliary image has to be specified as input, instead of the beauty image. This can be done as a *prefiltering* step to further improve the quality of the denoised beauty image.

The RT filter has certain limitations regarding the supported input images. Most notably, it cannot denoise images that were not rendered with ray tracing. Another important limitation is related to anti-aliasing filters. Most renderers use a high-quality pixel reconstruction filter instead of a trivial box filter to minimize aliasing artifacts (e.g. Gaussian, Blackman-Harris). The RT filter does support such pixel filters but only if implemented with importance sampling. Weighted pixel sampling (sometimes called *splatting*) introduces correlation between neighboring pixels, which causes the denoising to fail (the noise will not be filtered), thus it is not supported.

The filter can be created by passing "RT" to the `oidnNewFilter` function as the filter type. The filter supports the parameters listed in the table below. All specified images must have the same dimensions. The output image can be one of the input images (i.e. in-place denoising is supported). See section *Examples* for simple code snippets that demonstrate the usage of the filter.

Table 25: Parameters supported by the RT filter.

Type	Name	Default	Description
Image	color	optional	input beauty image (3 channels, LDR values in [0, 1] or HDR values in [0, +∞), values being interpreted such that, after scaling with the <code>inputScale</code> parameter, a value of 1 corresponds to a luminance level of 100 cd/m ²)
Image	albedo	optional	input auxiliary image containing the albedo per pixel (3 channels, values in [0, 1])
Image	normal	optional	input auxiliary image containing the shading normal per pixel (3 channels, world-space or view-space vectors with arbitrary length, values in [-1, 1])
Image	output		output image (3 channels); can be one of the input images
bool	hdr	false	whether the main input image is HDR
bool	srgb	false	whether the main input image is encoded with the sRGB (or 2.2 gamma) curve (LDR only) or is linear; the output will be encoded with the same curve
float	inputScale		scales values in the main input image before filtering, without scaling the output too, which can be used to map color or auxiliary feature values to the expected range, e.g. for mapping HDR values to physical units (which affects the quality of the output but <i>not</i> the range of the output values); if set to NaN, the scale is computed implicitly for HDR images or set to 1 otherwise
bool	cleanAux	false	whether the auxiliary feature (albedo, normal) images are noise-free; recommended for highest quality but should <i>not</i> be enabled for noisy auxiliary images to avoid residual noise
Data	weights	optional	trained model weights blob
int	maxMem	300MB	Approximate maximum scratch memory to use in megabytes (actual memory usage may be higher); limiting memory usage may cause slower denoising due to internally splitting the image into overlapping tiles
const int	alignment		when manually denoising in tiles, the tile size and offsets should be multiples of this amount of pixels to avoid artifacts; when denoising HDR images <code>inputScale</code> <i>must</i> be set by the user to avoid seam artifacts
const int	overlap		when manually denoising in tiles, the tiles should overlap by this amount of pixels

Using auxiliary feature images like albedo and normal helps preserving fine details and textures in the image thus can significantly improve denoising quality. These images should typically contain feature values for the first hit (i.e. the surface which is directly visible) per pixel. This works well for most surfaces but does not provide any benefits for reflections and objects visible through transparent surfaces (compared to just using the color as input). However, this issue can be usually fixed by storing feature values for a subsequent hit (i.e. the reflection and/or refraction) instead of the first hit. For example, it usually works well to follow perfect specular (*delta*) paths and store features for the first diffuse or glossy surface hit instead (e.g. for perfect specular dielectrics and mirrors). This can greatly improve the quality of reflections and transmission. We will describe this approach in more detail in the following subsections.

The auxiliary feature images should be as noise-free as possible. It is not a strict requirement but too much noise in the feature images may cause residual noise in the output. Ideally, these should be completely noise-free. If this is the case, this should be hinted to the filter using the `cleanAux` parameter to ensure the highest possible image quality. But this parameter should be used with care: if enabled, any noise present in the auxiliary images will end up in the denoised image as well, as residual noise. Thus, `cleanAux` should be enabled only if the auxiliary images are guaranteed to be noise-free.

Usually it is difficult to provide clean feature images, and some residual noise might be present in the output even with `cleanAux` being disabled. To eliminate this noise and to even improve the sharpness of texture details, the auxiliary images should be first denoised in a prefiltering step, as mentioned earlier. Then, these denoised auxiliary images could be used for denoising the beauty image. Since these are now noise-free, the `cleanAux` parameter should be enabled. See section *Denoising with prefiltering (C++11 API)* for a simple code example. Prefiltering makes denoising much more expensive but if there are multiple color AOVs to denoise, the prefiltered auxiliary images can be reused for

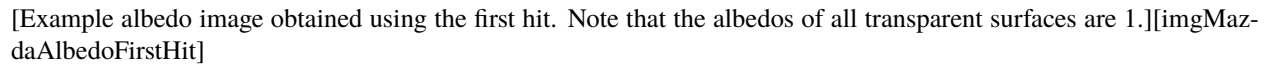

denoising multiple AOVs, amortizing the cost of the prefiltering step.

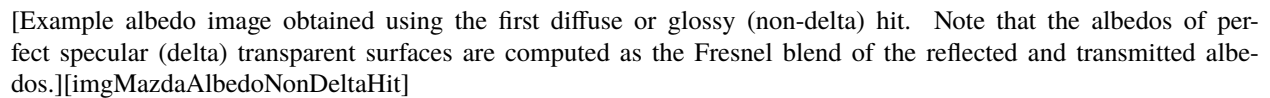

Thus, for final frame denoising, where the best possible image quality is required, it is recommended to prefilter the auxiliary features if they are noisy and enable the `cleanAux` parameter. Denoising with noisy auxiliary features should be reserved for previews and interactive rendering.

All auxiliary images should use the same pixel reconstruction filter as the beauty image. Using a properly anti-aliased beauty image but aliased albedo or normal images will likely introduce artifacts around edges.

Albedo

The albedo image is the feature image that usually provides the biggest quality improvement. It should contain the approximate color of the surfaces independent of illumination and viewing angle.

[Example albedo image obtained using the first hit. Note that the albedos of all transparent surfaces are 1.][imgMazdaAlbedoFirstHit]

[Example albedo image obtained using the first diffuse or glossy (non-delta) hit. Note that the albedos of perfect specular (delta) transparent surfaces are computed as the Fresnel blend of the reflected and transmitted albedos.][imgMazdaAlbedoNonDeltaHit]

For simple matte surfaces this means using the diffuse color/texture as the albedo. For other, more complex surfaces it is not always obvious what is the best way to compute the albedo, but the denoising filter is flexible to a certain extent and works well with differently computed albedos. Thus it is not necessary to compute the strict, exact albedo values but must be always between 0 and 1.

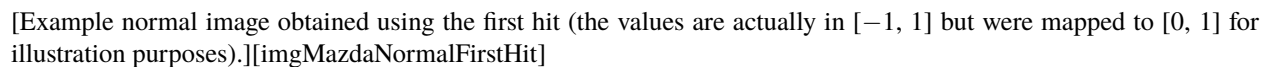

For metallic surfaces the albedo should be either the reflectivity at normal incidence (e.g. from the artist friendly metallic Fresnel model) or the average reflectivity; or if these are constant (not textured) or unknown, the albedo can be simply 1 as well.

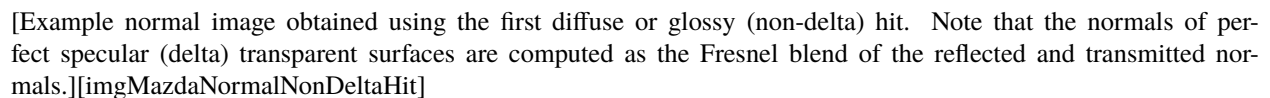

The albedo for dielectric surfaces (e.g. glass) should be either 1 or, if the surface is perfect specular (i.e. has a delta BSDF), the Fresnel blend of the reflected and transmitted albedos. The latter usually works better but only if it does not introduce too much noise or the albedo is prefiltered. If noise is an issue, we recommend to split the path into a reflected and a transmitted path at the first hit, and perhaps fall back to an albedo of 1 for subsequent dielectric hits. The reflected albedo in itself can be used for mirror-like surfaces as well.

The albedo for layered surfaces can be computed as the weighted sum of the albedos of the individual layers. Non-absorbing clear coat layers can be simply ignored (or the albedo of the perfect specular reflection can be used as well) but absorption should be taken into account.

Normal

The normal image should contain the shading normals of the surfaces either in world-space or view-space. It is recommended to include normal maps to preserve as much detail as possible.

[Example normal image obtained using the first hit (the values are actually in $[-1, 1]$ but were mapped to $[0, 1]$ for illustration purposes.)[imgMazdaNormalFirstHit]

[Example normal image obtained using the first diffuse or glossy (non-delta) hit. Note that the normals of perfect specular (delta) transparent surfaces are computed as the Fresnel blend of the reflected and transmitted normals.][imgMazdaNormalNonDeltaHit]

Just like any other input image, the normal image should be anti-aliased (i.e. by accumulating the normalized normals per pixel). The final accumulated normals do not have to be normalized but must be in the $[-1, 1]$ range (i.e. normals mapped to $[0, 1]$ are *not* acceptable and must be remapped to $[-1, 1]$).

Similar to the albedo, the normal can be stored for either the first or a subsequent hit (if the first hit has a perfect specular/delta BSDF).

Weights

Instead of using the built-in trained models for filtering, it is also possible to specify user-trained models at runtime. This can be achieved by passing the model *weights* blob corresponding to the specified set of features and other filter parameters, produced by the included training tool. See Section [Training] for details.

RTLighmap

The RTLighmap filter is a variant of the RT filter optimized for denoising HDR and normalized directional (e.g. spherical harmonics) lightmaps. It does not support LDR images.

The filter can be created by passing "RTLighmap" to the `oidnNewFilter` function as the filter type. The filter supports the following parameters:

Table 26: Parameters supported by the RTLighmap filter.

Type	Name	De- fault	Description
Image	color		input beauty image (3 channels, HDR values in $[0, +\infty)$, interpreted such that, after scaling with the <code>inputScale</code> parameter, a value of 1 corresponds to aluminance level of 100 cd/m ² ; directional values in $[-1, 1]$)
Image	output		output image (3 channels); can be one of the input images
bool	directional	false	whether the input contains normalized coefficients (in $[-1, 1]$) of a directional lightmap (e.g. normalized L1 or higher spherical harmonics band with the L0 band divided out); if the range of the coefficients is different from $[-1, 1]$, the <code>inputScale</code> parameter can be used to adjust the range without changing the stored values
float	inputScale	1	scales input color values before filtering, without scaling the output too, which can be used to map color values to the expected range, e.g. for mapping HDR values to physical units (which affects the quality of the output but <i>not</i> the range of the output values); if set to NaN, the scale is computed implicitly for HDR images or set to 1 otherwise
Data	weights	directional	trained model weights blob
int	maxMemory	300MB	approximate maximum scratch memory to use in megabytes (actual memory usage may be higher); limiting memory usage may cause slower denoising due to internally splitting the image into overlapping tiles
const int	alignment		when manually denoising in tiles, the tile size and offsets should be multiples of this amount of pixels to avoid artifacts; when denoising HDR images <code>inputScale</code> <i>must</i> be set by the user to avoid seam artifacts
const int	overlap		when manually denoising in tiles, the tiles should overlap by this amount of pixels

Training

The Intel Open Image Denoise source distribution includes a Python-based neural network training toolkit (located in the `training` directory), which can be used to train the denoising filter models with image datasets provided by the user. This is an advanced feature of the library which usage requires some background knowledge of machine learning and basic familiarity with deep learning frameworks and toolkits (e.g. PyTorch or TensorFlow, TensorBoard).

The training toolkit consists of the following command-line scripts:

- `preprocess.py`: Preprocesses training and validation datasets.
- `train.py`: Trains a model using preprocessed datasets.

- `infer.py`: Performs inference on a dataset using the specified training result.
- `export.py`: Exports a training result to the runtime model weights format.
- `find_lr.py`: Tool for finding the optimal minimum and maximum learning rates.
- `visualize.py`: Invokes TensorBoard for visualizing statistics of a training result.
- `split_exr.py`: Splits a multi-channel EXR image into multiple feature images.
- `convert_image.py`: Converts a feature image to a different image format.
- `compare_image.py`: Compares two feature images using the specified quality metrics.

Prerequisites

Before you can run the training toolkit you need the following prerequisites:

- Linux (other operating systems are currently not supported)
- Python 3.7 or later
- PyTorch 1.8 or later
- NumPy 1.19 or later
- OpenImageIO 2.1 or later
- TensorBoard 2.4 or later (*optional*)

Devices

Most scripts in the training toolkit support selecting what kind of device (e.g. CPU, GPU) to use for the computations (`--device` or `-d` option). If multiple devices of the same kind are available (e.g. multiple GPUs), the user can specify which one of these to use (`--device_id` or `-k` option). Additionally, some scripts, like `train.py`, support data-parallel execution on multiple devices for faster performance (`--num_devices` or `-n` option).

Datasets

A dataset should consist of a collection of noisy and corresponding noise-free reference images. It is possible to have more than one noisy version of the same image in the dataset, e.g. rendered at different samples per pixel and/or using different seeds.

The training toolkit expects to have all datasets (e.g. training, validation) in the same parent directory (e.g. `data`). Each dataset is stored in its own subdirectory (e.g. `train`, `valid`), which can have an arbitrary name.

The images must be stored in OpenEXR format (`.exr` files), and the filenames must have a specific format but the files can be stored in an arbitrary directory structure inside the dataset directory. The only restriction is that all versions of an image (noisy images and the reference image) must be located in the same subdirectory. Each feature of an image (e.g. color, albedo) must be stored in a separate image file, i.e. multi-channel EXR image files are not supported. If you have multi-channel EXRs, you can split them into separate images per feature using the included `split_exr.py` tool.

An image filename must consist of a base name, a suffix with the number of samples per pixel or whether it is the reference image (e.g. `_0128spp`, `_ref`), the feature type extension (e.g. `.hdr`, `.alb`), and the image format extension (`.exr`). The exact filename format as a regular expression is the following:

```
[.]+(?:[0-9]+(spp)?|ref|reference|tgt|target)\N\.(hdr|ldr|sh1[xyz]|alb|nrm)\N.exr
```

The number of samples per pixel should be padded with leading zeros to have a fixed number of digits. If the reference image is not explicitly named as such (i.e. has the number of samples instead), the image with the most samples per pixel will be considered the reference.

The following image features are supported:

Table 27: Image features supported by the training toolkit.

Feature	Description	Channels	File extension
hdr	color (HDR)	3	.hdr.exr
ldr	color (LDR)	3	.ldr.exr
sh1	color (normalized L1 spherical harmonics)	3 × 3 images	.sh1x.exr, .sh1y.exr, .sh1z.exr
alb	albedo	3	.alb.exr
nrm	normal	3	.nrm.exr

The following directory tree demonstrates an example root dataset directory (`data`) containing one dataset (`rt_train`) with HDR color and albedo feature images:

```
data
|-- rt_train
    |-- scene1
        |-- view1_0001.alb.exr
        |-- view1_0001.hdr.exr
        |-- view1_0004.alb.exr
        |-- view1_0004.hdr.exr
        |-- view1_8192.alb.exr
        |-- view1_8192.hdr.exr
        |-- view2_0001.alb.exr
        |-- view2_0001.hdr.exr
        |-- view2_8192.alb.exr
        |-- view2_8192.hdr.exr
    |-- scene2_000008spp.alb.exr
    |-- scene2_000008spp.hdr.exr
    |-- scene2_000064spp.alb.exr
    |-- scene2_000064spp.hdr.exr
    |-- scene2_reference.alb.exr
    |-- scene2_reference.hdr.exr
```

Preprocessing (preprocess.py)

Training and validation datasets can be used only after preprocessing them using the `preprocess.py` script. This will convert the specified training (`--train_data` or `-t` option) and validation datasets (`--valid_data` or `-v` option) located in the root dataset directory (`--data_dir` or `-D` option) to a format that can be loaded more efficiently during training. All preprocessed datasets will be stored in a root preprocessed dataset directory (`--preproc_dir` or `-P` option).

The preprocessing script requires the set of image features to include in the preprocessed dataset as command-line arguments. Only these specified features will be available for training but it is not required to use all of them at the same time. Thus, a single preprocessed dataset can be reused for training multiple models with different combinations of the preprocessed features.

By default, all input features are assumed to be noisy, including the auxiliary features (e.g. albedo, normal), each having versions at different samples per pixel. However, it is also possible to train with noise-free auxiliary features, in which case the reference auxiliary features are used instead of the various noisy ones (`--clean_aux` option).

Preprocessing also depends on the filter that will be trained (e.g. determines which HDR/LDR transfer function has to be used), which should be also specified (`--filter` or `-f` option). The alternative is to manually specify the transfer function (`--transfer` or `-x` option) and other filter-specific parameters, which could be useful for training custom filters.

For example, to preprocess the training and validation datasets (`rt_train` and `rt_valid`) with HDR color, albedo, and normal image features, for training the RT filter, the following command can be used:

```
./preprocess.py hdr alb nrm --filter RT --train_data rt_train --valid_data rt_valid
```

It is possible to preprocess the same dataset multiple times, with possibly different combinations of features and options. The training script will use the most suitable and most recent preprocessed version depending on the training parameters.

For more details about using the preprocessing script, including other options, please have a look at the help message:

```
./preprocess.py -h
```

Training (train.py)

The filters require separate trained models for each supported combination of input features. Thus, depending on which combinations of features the user wants to support for a particular filter, one or more models have to be trained.

After preprocessing the datasets, it is possible to start training a model using the `train.py` script. Similar to the preprocessing script, the input features must be specified (could be a subset of the preprocessed features), and the dataset names, directory paths, and the filter can be also passed.

The tool will produce a training *result*, the name of which can be either specified (`--result` or `-r` option) or automatically generated (by default). Each result is stored in its own subdirectory, and these are located in a common parent directory (`--results_dir` or `-R` option). If a training result already exists, the tool will resume training that result from the latest checkpoint.

The default training hyperparameters should work reasonably well in general, but some adjustments might be necessary for certain datasets to attain optimal performance, most importantly: the number of epochs (`--num_epochs` or `-e` option), the global mini-batch size (`--batch_size` or `-b` option), and the learning rate. The training tool uses a one-cycle learning rate schedule with cosine annealing, which can be configured by setting the base learning rate (`--learning_rate` or `--lr` option), the maximum learning rate (`--max_learning_rate` or `--max_lr` option), and the percentage of the cycle spent increasing the learning rate (`--learning_rate_warmup` or `--lr_warmup` option).

Example usage:

```
./train.py hdr alb --filter RT --train_data rt_train --valid_data rt_valid --result rt_
↪hdr_alb
```

For finding the optimal learning rate range, we recommend using the included `find_lr.py` script, which trains one epoch using an increasing learning rate and logs the resulting losses in a comma-separated values (CSV) file. Plotting the loss curve can show when the model starts to learn (the base learning rate) and when it starts to diverge (the maximum learning rate).

The model is evaluated with the validation dataset at regular intervals (`--num_valid_epochs` option), and checkpoints are also regularly created (`--num_save_epochs` option) to save training progress. Also, some statistics are logged (e.g. training and validation losses, learning rate) per epoch, which can be later visualized with TensorBoard by running the `visualize.py` script, e.g.:

```
./visualize.py --result rt_hdr_alb
```

Training is performed with mixed precision (FP16 and FP32) by default, if it supported by the hardware, which makes training faster and use less memory. However, in some rare cases this might cause some convergence issues. The training precision can be manually set to FP32 if necessary (`--precision` or `-p` option).

Inference (infer.py)

A training result can be tested by performing inference on an image dataset (`--input_data` or `-i` option) using the `infer.py` script. The dataset does *not* have to be preprocessed. In addition to the result to use, it is possible to specify which checkpoint to load as well (`-e` or `--num_epochs` option). By default the latest checkpoint is loaded.

The tool saves the output images in a separate directory (`--output_dir` or `-O` option) in the requested formats (`--format` or `-F` option). It also evaluates a set of image quality metrics (`--metric` or `-M` option), e.g. PSNR, SSIM, for images that have reference images available. All metrics are computed in tonemapped non-linear sRGB space. Thus, HDR images are first tonemapped (with Naughty Dog's Filmic Tonemapper from John Hable's *Uncharted 2: HDR Lighting* presentation) and converted to sRGB before evaluating the metrics.

Example usage:

```
./infer.py --result rt_hdr_alb --input_data rt_test --format exr png --metric ssim
```

The inference tool supports prefiltering of auxiliary features as well, which can be performed by specifying the list of training results for each feature to prefilter (`--aux_results` or `-a` option). This is primarily useful for evaluating the quality of models trained with clean auxiliary features.

Exporting Results (export.py)

The training result produced by the `train.py` script cannot be immediately used by the main library. It has to be first exported to the runtime model weights format, a *Tensor Archive* (TZA) file. Running the `export.py` script for a training result (and optionally a checkpoint epoch) will create a binary `.tza` file in the directory of the result, which can be either used at runtime through the API or it can be included in the library build by replacing one of the built-in weights files.

Example usage:

```
./export.py --result rt_hdr_alb
```

Image Conversion and Comparison

In addition to the already mentioned `split_exr.py` script, the toolkit contains a few other image utilities as well.

`convert_image.py` converts a feature image to a different image format (and/or a different feature, e.g. HDR color to LDR), performing tonemapping and other transforms as well if needed. For HDR images the exposure can be adjusted by passing a linear exposure scale (`--exposure` or `-E` option). Example usage:

```
./convert_image.py view1_0004.hdr.exr view1_0004.png --exposure 2.5
```

The `compare_image.py` script compares two feature images (preferably having the dataset filename format to correctly detect the feature) using the specified image quality metrics, similar to the `infer.py` tool. Example usage:

```
./compare_image.py view1_0004.hdr.exr view1_8192.hdr.exr --exposure 2.5 --metric mse ssim
```

OSPRay

OSPRay is a scalable, and portable ray tracing engine for high-performance, high-fidelity visualization.

Introduction

OSPRay is a scalable, and portable ray tracing engine for high-performance, high-fidelity visualization.

The purpose of OSPRay is to provide an open, powerful, and easy-to-use rendering library that allows one to easily build applications that use ray tracing based rendering for interactive applications (including both surface- and volume-based visualizations).

OSPRay API

To access the OSPRay API you first need to include the OSPRay header

```
#include "ospray/ospray.h"
```

where the API is compatible with C99 and C++.

Initialization and Shutdown

To use the API, OSPRay must be initialized with a “device”. A device is the object which implements the API. Creating and initializing a device can be done in either of two ways: command line arguments using `ospInit` or manually instantiating a device and setting parameters on it.

Command Line Arguments

The first is to do so by giving OSPRay the command line from `main()` by calling

```
OSPError ospInit(int *argc, const char **argv);
```

OSPRay parses (and removes) its known command line parameters from your application’s `main` function. For an example see the *tutorial*. For possible error codes see section *Error Handling and Status Messages*. It is important to note that the arguments passed to `ospInit()` are processed in order they are listed. The following parameters (which are prefixed by convention with “`--osp:`”) are understood:

Table 28: Command line parameters accepted by OSPRay's `ospInit`.

Parameter	Description
<code>--osp:debug</code>	enables various extra checks and debug output, and disables multi-threading
<code>--osp:num-threads=<n></code>	use <code>n</code> threads instead of per default using all detected hardware threads
<code>--osp:log-level=<str></code>	set logging level; valid values (in order of severity) are <code>none</code> , <code>error</code> , <code>warning</code> , <code>info</code> , and <code>debug</code>
<code>--osp:warn-as-error</code>	send <code>warning</code> and <code>error</code> messages through the error callback, otherwise send <code>warning</code> messages through the message callback; must have sufficient <code>logLevel</code> to enable warnings
<code>--osp:verbose</code>	shortcut for <code>--osp:log-level=info</code> and enable debug output on <code>cout</code> , error output on <code>cerr</code>
<code>--osp:vv</code>	shortcut for <code>--osp:log-level=debug</code> and enable debug output on <code>cout</code> , error output on <code>cerr</code>
<code>--osp:load-modules=<name>[...]</code>	load one or more modules during initialization; equivalent to calling <code>ospLoadModule(name)</code>
<code>--osp:log-output=<dst></code>	convenience for setting where status messages go; valid values for <code>dst</code> are <code>cerr</code> and <code>cout</code>
<code>--osp:error-output=<dst></code>	convenience for setting where error messages go; valid values for <code>dst</code> are <code>cerr</code> and <code>cout</code>
<code>--osp:device=<name></code>	use <code>name</code> as the type of device for OSPRay to create; e.g., <code>--osp:device=cpu</code> gives you the default <code>cpu</code> device; Note if the device to be used is defined in a module, remember to pass <code>--osp:load-modules=<name> first</code>
<code>--osp:set-affinity=<fn></code>	bind software threads to hardware threads; <code>0</code> disables binding; default is <code>1</code> on KNL and <code>0</code> otherwise
<code>--osp:device-param=<param>=<value>[...]</code>	set <code>param</code> to <code>value</code> (device parameters; equivalent to calling <code>ospDeviceSet*(param, value)</code>)

Manual Device Instantiation

The second method of initialization is to explicitly create the device and possibly set parameters. This method looks almost identical to how other *objects* are created and used by OSPRay (described in later sections). The first step is to create the device with

```
OSPDevice ospNewDevice(const char *type);
```

where the `type` string maps to a specific device implementation. OSPRay always provides the “`cpu`” device, which maps to a fast, local CPU implementation. Other devices can also be added through additional modules, such as distributed MPI device implementations.

Once a device is created, you can call

```
void ospDeviceSetParam(OSPObject, const char *id, OSPDataType type, const void *mem);
```

to set parameters on the device. The semantics of setting parameters is exactly the same as `ospSetParam`, which is documented below in the *parameters* section. The following parameters can be set on all devices:

Table 29: Parameters shared by all devices.

Type	Name	Description
int	numThreads	number of threads which OSPRay should use
int	logLevel	logging level; valid values (in order of severity) are OSP_LOG_NONE, OSP_LOG_ERROR, OSP_LOG_WARNING, OSP_LOG_INFO, and OSP_LOG_DEBUG
string	logOutput	convenience for setting where status messages go; valid values are cerr and cout
string	errorOutput	convenience for setting where error messages go; valid values are cerr and cout
bool	debug	set debug mode; equivalent to logLevel=debug and numThreads=1
bool	warnAsError	send warning and error messages through the error callback, otherwise send warning messages through the message callback; must have sufficient logLevel to enable warnings
bool	setAffinity	bind software threads to hardware threads if set to 1; 0 disables binding omitting the parameter will let OSPRay choose

Once parameters are set on the created device, the device must be committed with

```
void ospDeviceCommit(OSPDevice);
```

To use the newly committed device, you must call

```
void ospSetCurrentDevice(OSPDevice);
```

This then sets the given device as the object which will respond to all other OSPRay API calls.

Device handle lifetimes are managed with two calls, the first which increments the internal reference count to the given `OSPDevice`

```
void ospDeviceRetain(OSPDevice)
```

and the second which decrements the reference count

```
void ospDeviceRelease(OSPDevice)
```

Users can change parameters on the device after initialization (from either method above), by calling

```
OSPDevice ospGetCurrentDevice();
```

This function returns the handle to the device currently used to respond to OSPRay API calls, where users can set/change parameters and recommit the device. If changes are made to the device that is already set as the current device, it does not need to be set as current again. Note this API call will increment the ref count of the returned device handle, so applications must use `ospDeviceRelease` when finished using the handle to avoid leaking the underlying device object. If there is no current device set, this will return an invalid NULL handle.

When a device is created, its reference count is initially 1. When a device is set as the current device, it internally has its reference count incremented. Note that `ospDeviceRetain` and `ospDeviceRelease` should only be used with reference counts that the application tracks: removing reference held by the current set device should be handled by `ospShutdown`. Thus, `ospDeviceRelease` should only decrement the reference counts that come from `ospNewDevice`, `ospGetCurrentDevice`, and the number of explicit calls to `ospDeviceRetain`.

OSPRay allows applications to query runtime properties of a device in order to do enhanced validation of what device was loaded at runtime. The following function can be used to get these device-specific properties (attributes about the

device, not parameter values)

```
int64_t ospDeviceGetProperty(OSPDevice, OSPDeviceProperty);
```

It returns an integer value of the queried property and the following properties can be provided as parameter:

```
OSP_DEVICE_VERSION
OSP_DEVICE_VERSION_MAJOR
OSP_DEVICE_VERSION_MINOR
OSP_DEVICE_VERSION_PATCH
OSP_DEVICE_SO_VERSION
```

Environment Variables

OSPRay's generic device parameters can be overridden via environment variables for easy changes to OSPRay's behavior without needing to change the application (variables are prefixed by convention with "OSPRAY_"):

Table 30: Environment variables interpreted by OSPRay.

Variable	Description
OS-PRAY_NUM_THREADS	equivalent to <code>--osp:num-threads</code>
OS-PRAY_LOG_LEVEL	equivalent to <code>--osp:log-level</code>
OS-PRAY_LOG_OUTPUT	equivalent to <code>--osp:log-output</code>
OS-PRAY_ERROR_OUTPUT	equivalent to <code>--osp:error-output</code>
OSPRAY_DEBUG	equivalent to <code>--osp:debug</code>
OS-PRAY_WARN_AS_ERROR	equivalent to <code>--osp:warn-as-error</code>
OS-PRAY_SET_AFFINITY	equivalent to <code>--osp:set-affinity</code>
OS-PRAY_LOAD_MODULES	equivalent to <code>--osp:load-modules</code> , can be a comma separated list of modules which will be loaded in order
OSPRAY_DEVICE	equivalent to <code>--osp:device:</code>

Note that these environment variables take precedence over values specified through `ospInit` or manually set device parameters.

Error Handling and Status Messages

The following errors are currently used by OSPRay:

Table 31: Possible error codes, i.e., valid named constants of type `OSPError`.

Name	Description
<code>OSP_NO_ERROR</code>	no error occurred
<code>OSP_UNKNOWN_ERROR</code>	an unknown error occurred
<code>OSP_INVALID_ARGUMENT</code>	an invalid argument was specified
<code>OSP_INVALID_OPERATION</code>	the operation is not allowed for the specified object
<code>OSP_OUT_OF_MEMORY</code>	there is not enough memory to execute the command
<code>OSP_UNSUPPORTED_CPU</code>	the CPU is not supported (minimum ISA is SSE4.1 on x86_64 and NEON on ARM64)
<code>OSP_VERSION_MISMATCH</code>	a module could not be loaded due to mismatching version

These error codes are either directly return by some API functions, or are recorded to be later queried by the application via

```
OSPError ospDeviceGetLastErrorCode(OSPDevice);
```

A more descriptive error message can be queried by calling

```
const char* ospDeviceGetLastErrorMsg(OSPDevice);
```

Alternatively, the application can also register a callback function of type

```
typedef void (*OSPErrorCallback)(void *userData, OSPError, const char* errorDetails);
```

via

```
void ospDeviceSetErrorCallback(OSPDevice, OSPErrorCallback, void *userData);
```

to get notified when errors occur.

Applications may be interested in messages which OSPRay emits, whether for debugging or logging events. Applications can call

```
void ospDeviceSetStatusCallback(OSPDevice, OSPStatusCallback, void *userData);
```

in order to register a callback function of type

```
typedef void (*OSPStatusCallback)(void *userData, const char* messageText);
```

which OSPRay will use to emit status messages. By default, OSPRay uses a callback which does nothing, so any output desired by an application will require that a callback is provided. Note that callbacks for C++ `std::cout` and `std::cerr` can be alternatively set through `ospInit()` or the `OSPRAY_LOG_OUTPUT` environment variable.

Applications can clear either callback by passing `NULL` instead of an actual function pointer.

Loading OSPRay Extensions at Runtime

OSPRay’s functionality can be extended via plugins (which we call “modules”), which are implemented in shared libraries. To load module name from `libospray_module_<name>.so` (on Linux and Mac OS X) or `ospray_module_<name>.dll` (on Windows) use

```
OSPError ospLoadModule(const char *name);
```

Modules are searched in OS-dependent paths. `ospLoadModule` returns `OSP_NO_ERROR` if the plugin could be successfully loaded.

Shutting Down OSPRay

When the application is finished using OSPRay (typically on application exit), the OSPRay API should be finalized with

```
void ospShutdown();
```

This API call ensures that the current device is cleaned up appropriately. Due to static object allocation having non-deterministic ordering, it is recommended that applications call `ospShutdown()` before the calling application process terminates.

Objects

All entities of OSPRay (the *renderer*, *volumes*, *geometries*, *lights*, *cameras*, ...) are a logical specialization of `OSPObject` and share common mechanism to deal with parameters and lifetime.

An important aspect of object parameters is that parameters do not get passed to objects immediately. Instead, parameters are not visible at all to objects until they get explicitly committed to a given object via a call to

```
void ospCommit(OSPObject);
```

at which time all previously additions or changes to parameters are visible at the same time. If a user wants to change the state of an existing object (e.g., to change the origin of an already existing camera) it is perfectly valid to do so, as long as the changed parameters are recommitted.

The commit semantic allow for batching up multiple small changes, and specifies exactly when changes to objects will occur. This can impact performance and consistency for devices crossing a PCI bus or across a network.

Note that OSPRay uses reference counting to manage the lifetime of all objects, so one cannot explicitly “delete” any object. Instead, to indicate that the application does not need and does not access the given object anymore, call

```
void ospRelease(OSPObject);
```

This decreases its reference count and if the count reaches 0 the object will automatically get deleted. Passing `NULL` is not an error. Note that every handle returned via the API needs to be released when the object is no longer needed, to avoid memory leaks.

Sometimes applications may want to have more than one reference to an object, where it is desirable for the application to increment the reference count of an object. This is done with

```
void ospRetain(OSPObject);
```

It is important to note that this is only necessary if the application wants to call `ospRelease` on an object more than once: objects which contain other objects as parameters internally increment/decrement ref counts and should not be explicitly done by the application.

Parameters

Parameters allow to configure the behavior of and to pass data to objects. However, objects do *not* have an explicit interface for reasons of high flexibility and a more stable compile-time API. Instead, parameters are passed separately to objects in an arbitrary order, and unknown parameters will simply be ignored (though a warning message will be posted). The following function allows adding various types of parameters with name `id` to a given object:

```
void ospSetParam(OSPObject, const char *id, OSPDataType type, const void *mem);
```

The valid parameter names for all `OSPObject`s and what types are valid are discussed in future sections.

Note that `mem` must always be a pointer *to* the object, otherwise accidental type casting can occur. This is especially true for pointer types (`OSP_VOID_PTR` and `OSPObject` handles), as they will implicitly cast to `void*`, but be incorrectly interpreted. To help with some of these issues, there also exist variants of `ospSetParam` for specific types, such as `ospSetInt` and `ospSetVec3f` in the `OSPRay` utility library (found in `ospray_util.h`). Note that half precision float parameters `OSP_HALF`, `OSP_VEC[234]H` are not supported.

Users can also remove parameters that have been explicitly set from `ospSetParam`. Any parameters which have been removed will go back to their default value during the next commit unless a new parameter was set after the parameter was removed. To remove a parameter, use

```
void ospRemoveParam(OSPObject, const char *id);
```

Data

`OSPRay` consumes data arrays from the application using a specific object type, `OSPData`. There are several components to describing a data array: element type, 1/2/3 dimensional striding, and whether the array is shared with the application or copied into opaque, `OSPRay`-owned memory.

Shared data arrays require that the application's array memory outlives the lifetime of the created `OSPData`, as `OSPRay` is referring to application memory. Where this is not preferable, applications use opaque arrays to allow the `OSPData` to own the lifetime of the array memory. However, opaque arrays dictate the cost of copying data into it, which should be kept in mind.

Thus, the most efficient way to specify a data array from the application is to create a shared data array, which is done with

```
OSPData ospNewSharedData(const void *sharedData,
    OSPDataType,
    uint64_t numItems1,
    int64_t byteStride1 = 0,
    uint64_t numItems2 = 1,
    int64_t byteStride2 = 0,
    uint64_t numItems3 = 1,
    int64_t byteStride3 = 0);
```

The call returns an `OSPData` handle to the created array. The calling program guarantees that the `sharedData` pointer will remain valid for the duration that this data array is being used. The number of elements `numItems` must be positive (there cannot be an empty data object). The data is arranged in three dimensions, with specializations to two or one dimension (if some `numItems` are 1). The distance between consecutive elements (per dimension) is given in

bytes with `byteStride` and can also be negative. If `byteStride` is zero it will be determined automatically (e.g., as `sizeof(type)`). Strides do not need to be ordered, i.e., `byteStride2` can be smaller than `byteStride1`, which is equivalent to a transpose. However, if the stride should be calculated, then an ordering in dimensions is assumed to disambiguate, i.e., `byteStride1 < byteStride2 < byteStride3`.

The enum type `OSPDataType` describes the different element types that can be represented in `OSPRay`; valid constants are listed in the table below.

Table 32: Valid named constants for `OSPDataType`.

Type/Name	Description
<code>OSP_DEVICE</code>	API device object reference
<code>OSP_DATA</code>	data reference
<code>OSP_OBJECT</code>	generic object reference
<code>OSP_CAMERA</code>	camera object reference
<code>OSP_FRAMEBUFFER</code>	framebuffer object reference
<code>OSP_LIGHT</code>	light object reference
<code>OSP_MATERIAL</code>	material object reference
<code>OSP_TEXTURE</code>	texture object reference
<code>OSP_RENDERER</code>	renderer object reference
<code>OSP_WORLD</code>	world object reference
<code>OSP_GEOMETRY</code>	geometry object reference
<code>OSP_VOLUME</code>	volume object reference
<code>OSP_TRANSFER_FUNCTION</code>	transfer function object reference
<code>OSP_IMAGE_OPERATION</code>	image operation object reference
<code>OSP_STRING</code>	C-style zero-terminated character string
<code>OSP_CHAR, OSP_VEC[234]C</code>	8 bit signed character scalar and [234]-element vector
<code>OSP_UCHAR, OSP_VEC[234]UC</code>	8 bit unsigned character scalar and [234]-element vector
<code>OSP_SHORT, OSP_VEC[234]S</code>	16 bit unsigned integer scalar and [234]-element vector
<code>OSP_USHORT, OSP_VEC[234]US</code>	16 bit unsigned integer scalar and [234]-element vector
<code>OSP_INT, OSP_VEC[234]I</code>	32 bit signed integer scalar and [234]-element vector
<code>OSP_UINT, OSP_VEC[234]UI</code>	32 bit unsigned integer scalar and [234]-element vector
<code>OSP_LONG, OSP_VEC[234]L</code>	64 bit signed integer scalar and [234]-element vector
<code>OSP_ULONG, OSP_VEC[234]UL</code>	64 bit unsigned integer scalar and [234]-element vector
<code>OSP_HALF, OSP_VEC[234]H</code>	16 bit half precision floating-point scalar and [234]-element vector (IEEE 754 binary16)
<code>OSP_FLOAT, OSP_VEC[234]F</code>	32 bit single precision floating-point scalar and [234]-element vector
<code>OSP_DOUBLE, OSP_VEC[234]D</code>	64 bit double precision floating-point scalar and [234]-element vector
<code>OSP_BOX[1234]I</code>	32 bit integer box (lower + upper bounds)
<code>OSP_BOX[1234]F</code>	32 bit single precision floating-point box (lower + upper bounds)
<code>OSP_LINEAR[23]F</code>	32 bit single precision floating-point linear transform ([23] vectors)
<code>OSP_AFFINE[23]F</code>	32 bit single precision floating-point affine transform (linear transform plus translation)
<code>OSP_QUATF</code>	32 bit single precision floating-point quaternion, in (i, j, k, w) layout
<code>OSP_VOID_PTR</code>	raw memory address (only found in module extensions)

If the elements of the array are handles to objects, then their reference counter is incremented.

An opaque `OSPData` with memory allocated by `OSPRay` is created with

```
OSPData ospNewData(OSPDataType,
    uint64_t numItems1,
    uint64_t numItems2 = 1,
    uint64_t numItems3 = 1);
```

To allow for (partial) copies or updates of data arrays use

```
void ospCopyData(const OSPData source,
                OSPData destination,
                uint64_t destinationIndex1 = 0,
                uint64_t destinationIndex2 = 0,
                uint64_t destinationIndex3 = 0);
```

which will copy the whole¹ content of the source array into destination at the given location destinationIndex. The OSPDataTypes of the data objects must match. The region to be copied must be valid inside the destination, i.e., in all dimensions, destinationIndex + sourceSize <= destinationSize. The affected region [destinationIndex, destinationIndex + sourceSize) is marked as dirty, which may be used by OSPRay to only process or update that sub-region (e.g., updating an acceleration structure). If the destination array is shared with OSPData by the application (created with ospNewSharedData), then

- the source array must be shared as well (thus ospCopyData cannot be used to read opaque data)
- if source and destination memory overlaps (aliasing), then behavior is undefined
- except if source and destination regions are identical (including matching strides), which can be used by application to mark that region as dirty (instead of the whole OSPData)

To add a data array as parameter named id to another object call also use

```
void ospSetObject(OSPObject, const char *id, OSPData);
```

Volumes

Volumes are volumetric data sets with discretely sampled values in 3D space, typically a 3D scalar field. To create a new volume object of given type type use

```
OSPVolume ospNewVolume(const char *type);
```

Note that OSPRay’s implementation forwards type directly to Open VKL, allowing new Open VKL volume types to be usable within OSPRay without the need to change (or even recompile) OSPRay.

Structured Regular Volume

Structured volumes only need to store the values of the samples, because their addresses in memory can be easily computed from a 3D position. A common type of structured volumes are regular grids.

Structured regular volumes are created by passing the type string “structuredRegular” to ospNewVolume. Structured volumes are represented through an OSPData 3D array data (which may or may not be shared with the application). The voxel data must be laid out in xyz-order² and can be compact (best for performance) or can have a stride between voxels, specified through the byteStride1 parameter when creating the OSPData. Only 1D strides are supported, additional strides between scanlines (2D, byteStride2) and slices (3D, byteStride3) are not.

The parameters understood by structured volumes are summarized in the table below.

¹ The number of items to be copied is defined by the size of the source array.

² For consecutive memory addresses the x-index of the corresponding voxel changes the quickest.

Table 33: Configuration parameters for structured regular volumes.

Type	Name	Default	Description
vec3f	gridOrigin	(0, 0, 0)	origin of the grid in object-space
vec3f	gridSpacing	(1, 1, 1)	size of the grid cells in object-space
OSP-Data	data		the actual voxel 3D <i>data</i>
int	filter	OSP_VOLUME_FILTER_LINEAR	filter used for reconstructing the field, also allowed is OSP_VOLUME_FILTER_NEAREST and OSP_VOLUME_FILTER_TRICUBIC
int	gradientFilter	same as <i>filter</i>	filter used during gradient computations
float	background	NaN	value that is used when sampling an undefined region outside the volume domain

The size of the volume is inferred from the size of the 3D array *data*, as is the type of the voxel values (currently supported are: OSP_UCHAR, OSP_SHORT, OSP_USHORT, OSP_HALF, OSP_FLOAT, and OSP_DOUBLE).

Structured Spherical Volume

Structured spherical volumes are also supported, which are created by passing a type string of “structuredSpherical” to `ospNewVolume`. The grid dimensions and parameters are defined in terms of radial distance r , inclination angle θ , and azimuthal angle ϕ , conforming with the ISO convention for spherical coordinate systems. The coordinate system and parameters understood by structured spherical volumes are summarized below.

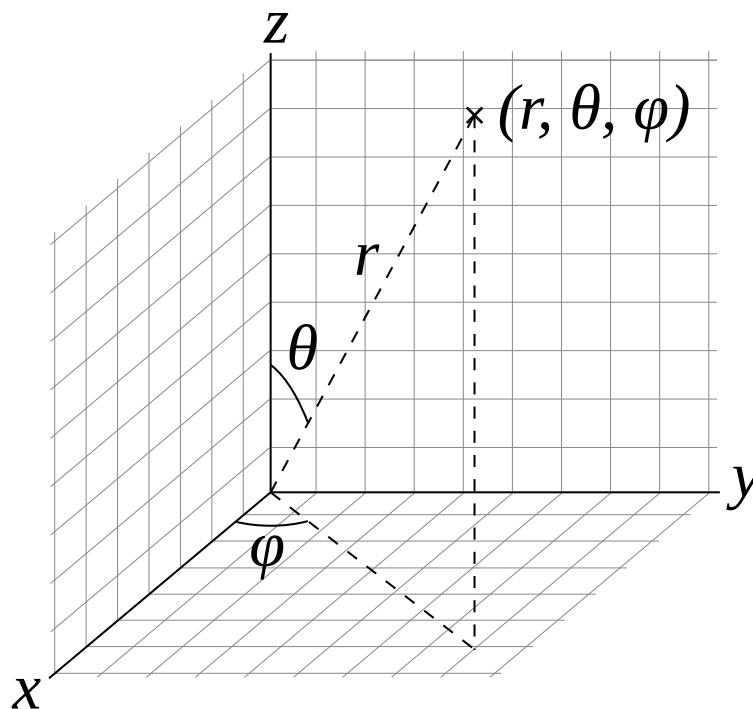

Fig. 3: Coordinate system of structured spherical volumes.

Table 34: Configuration parameters for structured spherical volumes.

Type	Name	Default	Description
vec3f	gridOrigin	(0, 0, 0)	origin of the grid in units of (r, θ, ϕ) ; angles in degrees
vec3f	gridSpacing	(1, 1, 1)	size of the grid cells in units of (r, θ, ϕ) ; angles in degrees
OSP-Data	data		the actual voxel 3D <i>data</i>
int	filter	OSP_VOLUME_FILTER_TRIANGLE	used for reconstructing the field, also allowed is OSP_VOLUME_FILTER_NEAREST
int	gradientFilter	same as <code>filter</code>	filter used during gradient computations
float	background	NaN	value that is used when sampling an undefined region outside the volume domain

The dimensions (r, θ, ϕ) of the volume are inferred from the size of the 3D array *data*, as is the type of the voxel values (currently supported are: OSP_UCHAR, OSP_SHORT, OSP_USHORT, OSP_HALF, OSP_FLOAT, and OSP_DOUBLE).

These grid parameters support flexible specification of spheres, hemispheres, spherical shells, spherical wedges, and so forth. The grid extents (computed as `[gridOrigin, gridOrigin + (dimensions - 1) * gridSpacing]`) however must be constrained such that:

- $r \geq 0$
- $0 \leq \theta \leq 180$
- $0 \leq \phi \leq 360$

Adaptive Mesh Refinement (AMR) Volume

OSPRay currently supports block-structured (Berger-Colella) AMR volumes. Volumes are specified as a list of blocks, which exist at levels of refinement in potentially overlapping regions. Blocks exist in a tree structure, with coarser refinement level blocks containing finer blocks. The cell width is equal for all blocks at the same refinement level, though blocks at a coarser level have a larger cell width than finer levels.

There can be any number of refinement levels and any number of blocks at any level of refinement. An AMR volume type is created by passing the type string “amr” to `ospNewVolume`.

Blocks are defined by three parameters: their bounds, the refinement level in which they reside, and the scalar data contained within each block.

Note that cell widths are defined *per refinement level*, not per block.

Table 35: Configuration parameters for AMR volumes.

Type	Name	Default	Description
OSPAMRMethod	method	OSP_AMR_CURRENT	OSPAMRMethod sampling method. Supported methods are: OSP_AMR_CURRENT OSP_AMR_FINEST OSP_AMR_OCTANT
float[]	cell-Width	NULL	array of each level's cell width
box3i[]	block.bound	NULL	<i>data</i> array of grid sizes (in voxels) for each AMR block
int[]	block.level	NULL	array of each block's refinement level
OSP-Data[]	block.data	NULL	<i>data</i> array of OSPData containing the actual scalar voxel data, only OSP_FLOAT is supported as OSPDataType
vec3f	gridOrigin	(0, 0, 0)	origin of the grid
vec3f	gridSpacing	(1, 1, 1)	size of the grid cells
float	back-ground	NaN	value that is used when sampling an undefined region outside the volume domain

Lastly, note that the `gridOrigin` and `gridSpacing` parameters act just like the structured volume equivalent, but they only modify the root (coarsest level) of refinement.

In particular, OSPRay's / Open VKL's AMR implementation was designed to cover Berger-Colella [1] and Chombo [2] AMR data. The `method` parameter above determines the interpolation method used when sampling the volume.

OSP_AMR_CURRENT finds the finest refinement level at that cell and interpolates through this "current" level

OSP_AMR_FINEST will interpolate at the closest existing cell in the volume-wide finest refinement level regardless of the sample cell's level

OSP_AMR_OCTANT interpolates through all available refinement levels at that cell. This method avoids discontinuities at refinement level boundaries at the cost of performance

Details and more information can be found in the publication for the implementation [3].

Unstructured Volume

Unstructured volumes can have their topology and geometry freely defined. Geometry can be composed of tetrahedral, hexahedral, wedge or pyramid cell types. The data format used is compatible with VTK and consists of multiple arrays: vertex positions and values, vertex indices, cell start indices, cell types, and cell values. An unstructured volume type is created by passing the type string “unstructured” to `ospNewVolume`.

Sampled cell values can be specified either per-vertex (`vertex.data`) or per-cell (`cell.data`). If both arrays are set, `cell.data` takes precedence.

Similar to a mesh, each cell is formed by a group of indices into the vertices. For each vertex, the corresponding (by array index) data value will be used for sampling when rendering, if specified. The index order for a tetrahedron is the same as `VTK_TETRA`: bottom triangle counterclockwise, then the top vertex.

For hexahedral cells, each hexahedron is formed by a group of eight indices into the vertices and data values. Vertex ordering is the same as `VTK_HEXAHEDRON`: four bottom vertices counterclockwise, then top four counterclockwise.

For wedge cells, each wedge is formed by a group of six indices into the vertices and data values. Vertex ordering is the same as `VTK_WEDGE`: three bottom vertices counterclockwise, then top three counterclockwise.

For pyramid cells, each cell is formed by a group of five indices into the vertices and data values. Vertex ordering is the same as `VTK_PYRAMID`: four bottom vertices counterclockwise, then the top vertex.

To maintain VTK data compatibility, the `index` array may be specified with cell sizes interleaved with vertex indices in the following format: $n, id_1, \dots, id_n, m, id_1, \dots, id_m$. This alternative `index` array layout can be enabled through the `indexPrefixed` flag (in which case, the `cell.type` parameter must be omitted).

Table 36: Configuration parameters for unstructured volumes.

Type	Name	De- fault	Description
vec3f[]	vertex.position		<i>data</i> array of vertex positions
float[]	vertex.data		<i>data</i> array of vertex data values to be sampled
uint32[] / uint64[]	index		<i>data</i> array of indices (into the vertex array(s)) that form cells
bool	indexPre- fixed	false	indicates that the <code>index</code> array is compatible to VTK, where the indices of each cell are prefixed with the number of vertices
uint32[] / uint64[]	cell.index		<i>data</i> array of locations (into the index array), specifying the first index of each cell
float[]	cell.data		<i>data</i> array of cell data values to be sampled
uint8[]	cell.type		<i>data</i> array of cell types (VTK compatible), only set if <code>indexPrefixed = false</code> . Supported types are:
			<code>OSP_TETRAHEDRON</code>
			<code>OSP_HEXAHEDRON</code>
			<code>OSP_WEDGE</code>
			<code>OSP_PYRAMID</code>
bool	hexItera- tive	false	hexahedron interpolation method, defaults to fast non-iterative version which could have rendering inaccuracies may appear if hex is not parallelepiped
bool	precom- putedNor- mals	false	whether to accelerate by precomputing, at a cost of 12 bytes/face
float	back- ground	NaN	value that is used when sampling an undefined region outside the volume domain

VDB Volume

VDB volumes implement a data structure that is very similar to the data structure outlined in Museth [1], they are created by passing the type string “vdb” to `ospNewVolume`.

The data structure is a hierarchical regular grid at its core: Nodes are regular grids, and each grid cell may either store a constant value (this is called a tile), or child pointers. Nodes in VDB trees are wide: Nodes on the first level have a resolution of 32^3 voxels, on the next level 16^3 , and on the leaf level 8^3 voxels. All nodes on a given level have the same resolution. This makes it easy to find the node containing a coordinate using shift operations (see [1]). VDB leaf nodes are implicit in OSPRay / Open VKL: they are stored as pointers to user-provided data.

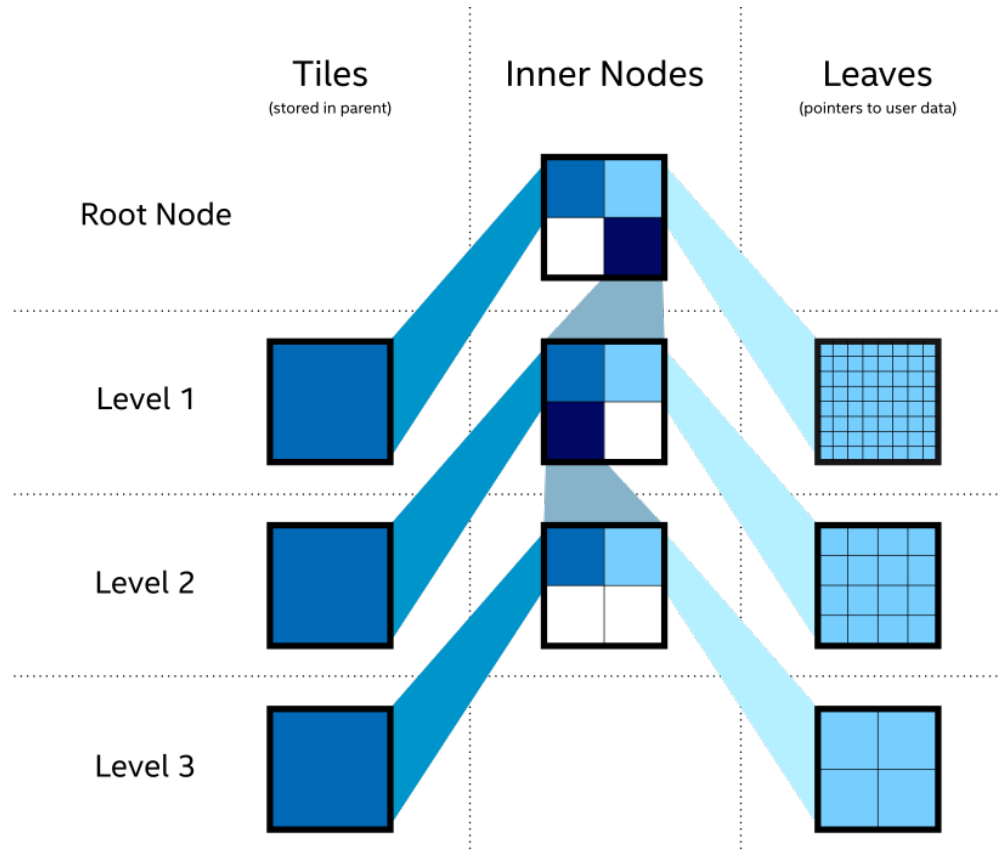

Fig. 4: Topology of VDB volumes.

VDB volumes interpret input data as constant cells (which are then potentially filtered). This is in contrast to `structuredRegular` volumes, which have a vertex-centered interpretation.

The VDB implementation in OSPRay / Open VKL follows the following goals:

- Efficient data structure traversal on vector architectures.
- Enable the use of industry-standard `.vdb` files created through the OpenVDB library.
- Compatibility with OpenVDB on a leaf data level, so that `.vdb` file may be loaded with minimal overhead.

VDB volumes have the following parameters:

Table 37: Configuration parameters for VDB volumes.

Type	Name	Description
int	maxSamplingDepth	do not descend further than to this depth during sampling, the maximum value and the default is 3
uint32_t	node.level	level on which each input node exists, may be 1, 2 or 3 (levels are counted from the root level = 0 down)
vec3i	node.origin	the node origin index (per input node)
OSPData[]	node.data	<i>data</i> arrays with the node data (per input node). Nodes that are tiles are expected to have single-item arrays. Leaf-nodes with grid data expected to have compact 3D arrays in zyx layout (z changes most quickly) with the correct number of voxels for the level. Only OSP_FLOAT is supported as field OSPDataType.
int	filter	filter used for reconstructing the field, default is OSP_VOLUME_FILTER_TRILINEAR, alternatively OSP_VOLUME_FILTER_NEAREST, or OSP_VOLUME_FILTER_TRICUBIC.
int	gradient-Filter	filter used for reconstructing the field during gradient computations, default same as <i>filter</i>
float	background	value that is used when sampling an undefined region outside the volume domain, default NaN

Particle Volume

Particle volumes consist of a set of points in space. Each point has a position, a radius, and a weight typically associated with an attribute. Particle volumes are created by passing the type string “particle” to `ospNewVolume`.

A radial basis function defines the contribution of that particle. Currently, we use the Gaussian radial basis function

$$\phi(P) = w \exp\left(-\frac{(P-p)^2}{2r^2}\right),$$

where P is the particle position, p is the sample position, r is the radius and w is the weight. At each sample, the scalar field value is then computed as the sum of each radial basis function ϕ , for each particle that overlaps it.

The OSPRay / Open VKL implementation is similar to direct evaluation of samples in Reda et al. [2]. It uses an Embree-built BVH with a custom traversal, similar to the method in [1].

Table 38: Configuration parameters for particle volumes.

Type	Name	Default	Description
vec3f[]	particle.position		<i>data</i> array of particle positions
float[]	particle.radius		<i>data</i> array of particle radii
float[]	particle.weight	NULL	optional <i>data</i> array of particle weights, specifying the height of the kernel.
float	radius-Support-Factor	3.0	The multiplier of the particle radius required for support. Larger radii ensure smooth results at the cost of performance. In the Gaussian kernel, the radius is one standard deviation (σ), so a value of 3 corresponds to 3σ .
float	clamp-Max-Cumulative-Value	0	The maximum cumulative value possible, set by user. All cumulative values will be clamped to this, and further traversal (RBF summation) of particle contributions will halt when this value is reached. A value of zero or less turns this off.
bool	estimateValueRanges	true	Enable heuristic estimation of value ranges which are used in internal acceleration structures as well as for determining the volume's overall value range. When set to false, the user <i>must</i> specify clampMaxCumulativeValue, and all value ranges will be assumed $[0-\text{clampMaxCumulativeValue}]$. Disabling this switch may improve volume commit time, but will make volume rendering less efficient.

Transfer Function

Transfer functions map the scalar values of volumes to color and opacity and thus they can be used to visually emphasize certain features of the volume. To create a new transfer function of given type `type` use

```
OSPTransferFunction ospNewTransferFunction(const char *type);
```

The returned handle can be assigned to a volumetric model (described below) as parameter "transferFunction" using `ospSetObject`.

One type of transfer function that is supported by OSPRay is the linear transfer function, which interpolates between given equidistant colors and opacities. It is create by passing the string "piecewiseLinear" to `ospNewTransferFunction` and it is controlled by these parameters:

Table 39: Parameters accepted by the linear transfer function.

Type	Name	Description
vec3f[]	color	<i>data</i> array of colors (linear RGB)
float[]	opacity	<i>data</i> array of opacities
vec2f	valueRange	domain (scalar range) this function maps from

The arrays `color` and `opacity` can be of different length.

VolumetricModels

Volumes in OSPRay are given volume rendering appearance information through `VolumetricModels`. This decouples the physical representation of the volume (and possible acceleration structures it contains) to rendering-specific parameters (where more than one set may exist concurrently). To create a volume instance, call

```
OSPVolumeModel ospNewVolumetricModel(OSPVolume volume);
```

The passed volume can be NULL as long as the volume to be used is passed as a parameter. If both a volume is specified on object creation and as a parameter, the parameter value is used. If the parameter value is later removed, the volume object passed on object creation is again used.

Table 40: Parameters understood by `VolumetricModel`.

Type	Name	Default	Description
OSPTransfer-Function	transfer-Function		<i>transfer function</i> to use
float	densityScale	1.0	makes volumes uniformly thinner or thicker
float	anisotropy	0.0	anisotropy of the (Henye-Greenstein) phase function in [-1-1] (<i>path tracer</i> only), default to isotropic scattering
OSPVolume	volume		optional <i>volume</i> object this model references

Geometries

Geometries in OSPRay are objects that describe intersectable surfaces. To create a new geometry object of given type use

```
OSPGeometry ospNewGeometry(const char *type);
```

Note that in the current implementation geometries are limited to a maximum of 2^{32} primitives.

Mesh

A mesh consisting of either triangles or quads is created by calling `ospNewGeometry` with type string “mesh”. Once created, a mesh recognizes the following parameters:

Table 41: Parameters defining a mesh geometry.

Type	Name	Description
vec3f[]	vertex.position	<i>data</i> array of vertex positions
vec3f[]	vertex.normal	<i>data</i> array of vertex normals
vec4f[] / vec3f[]	vertex.color	<i>data</i> array of vertex colors (linear RGBA/RGB)
vec2f[]	vertex.texcoord	<i>data</i> array of vertex texture coordinates
vec3ui[] / vec4ui[]	index	<i>data</i> array of (either triangle or quad) indices (into the vertex array(s))

The data type of index arrays differentiates between the underlying geometry, triangles are used for a index with `vec3ui` type and quads for `vec4ui` type. Quads are internally handled as a pair of two triangles, thus mixing triangles and quads is supported by encoding some triangle as a quad with the last two vertex indices being identical ($w=z$).

The `vertex.position` and `index` arrays are mandatory to create a valid mesh.

Subdivision

A mesh consisting of subdivision surfaces, created by specifying a geometry of type “subdivision”. Once created, a subdivision recognizes the following parameters:

Table 42: Parameters defining a Subdivision geometry.

Type	Name	Description
vec3f[]	<code>vertex.position</code>	<i>data</i> array of vertex positions
vec4f[]	<code>vertex.color</code>	optional <i>data</i> array of vertex colors (linear RGBA)
vec2f[]	<code>vertex.texcoord</code>	optional <i>data</i> array of vertex texture coordinates
float	<code>level</code>	global level of tessellation, default 5
uint[]	<code>index</code>	<i>data</i> array of indices (into the vertex array(s))
float[]	<code>index.level</code>	optional <i>data</i> array of per-edge levels of tessellation, overrides global level
uint[]	<code>face</code>	optional <i>data</i> array holding the number of indices/edges (3 to 15) per face, defaults to 4 (a pure quad mesh)
vec2i[]	<code>edge-Crease.index</code>	optional <i>data</i> array of edge crease indices
float[]	<code>edge-Crease.weight</code>	optional <i>data</i> array of edge crease weights
uint[]	<code>vertex-Crease.index</code>	optional <i>data</i> array of vertex crease indices
float[]	<code>vertex-Crease.weight</code>	optional <i>data</i> array of vertex crease weights
uchar	<code>mode</code>	subdivision edge boundary mode, supported modes are:
		OSP_SUBDIVISION_NO_BOUNDARY
		OSP_SUBDIVISION_SMOOTH_BOUNDARY (default)
		OSP_SUBDIVISION_PIN_CORNERS
		OSP_SUBDIVISION_PIN_BOUNDARY
		OSP_SUBDIVISION_PIN_ALL

The `vertex` and `index` arrays are mandatory to create a valid subdivision surface. If no `face` array is present then a pure quad mesh is assumed (the number of indices must be a multiple of 4). Optionally supported are edge and vertex creases.

Spheres

A geometry consisting of individual spheres, each of which can have an own radius, is created by calling `ospNewGeometry` with type string “sphere”. The spheres will not be tessellated but rendered procedurally and are thus perfectly round. To allow a variety of sphere representations in the application this geometry allows a flexible way of specifying the data of center position and radius within a *data* array:

Table 43: Parameters defining a spheres geometry.

Type	Name	Default	Description
vec3f[]	<code>sphere.position</code>		<i>data</i> array of center positions
float[]	<code>sphere.radius</code>	NULL	optional <i>data</i> array of the per-sphere radius
vec2f[]	<code>sphere.texcoord</code>	NULL	optional <i>data</i> array of texture coordinates (constant per sphere)
float	<code>radius</code>	0.01	default radius for all spheres (if <code>sphere.radius</code> is not set)

Curves

A geometry consisting of multiple curves is created by calling `ospNewGeometry` with type string “curve”. The parameters defining this geometry are listed in the table below.

Table 44: Parameters defining a curves geometry.

Type	Name	Description
vec4f[]	vertex.position_radius	<i>data</i> array of vertex position and per-vertex radius
vec2f[]	vertex.texcoord	<i>data</i> array of per-vertex texture coordinates
vec4f[]	vertex.color	<i>data</i> array of corresponding vertex colors (linear RGBA)
vec3f[]	vertex.normal	<i>data</i> array of curve normals (only for “ribbon” curves)
vec4f[]	vertex.tangent	<i>data</i> array of curve tangents (only for “hermite” curves)
uint32[]	index	<i>data</i> array of indices to the first vertex or tangent of a curve segment
uchar	type	OSPCurveType for rendering the curve. Supported types are:
		OSP_FLAT
		OSP_ROUND
		OSP_RIBBON
		OSP_DISJOINT
uchar	basis	OSPCurveBasis for defining the curve. Supported bases are:
		OSP_LINEAR
		OSP_BEZIER
		OSP_BSPLINE
		OSP_HERMITE
		OSP_CATMULL_ROM

Positions in `vertex.position_radius` parameter supports per-vertex varying radii with data type `vec4f[]` and instantiate Embree curves internally for the relevant type/basis mapping.

The following section describes the properties of different curve basis’ and how they use the data provided in data buffers:

OSP_LINEAR The indices point to the first of 2 consecutive control points in the vertex buffer. The first control point is the start and the second control point the end of the line segment. The curve goes through all control points listed in the vertex buffer.

OSP_BEZIER The indices point to the first of 4 consecutive control points in the vertex buffer. The first control point represents the start point of the curve, and the 4th control point the end point of the curve. The Bézier basis is interpolating, thus the curve does go exactly through the first and fourth control vertex.

OSP_BSPLINE The indices point to the first of 4 consecutive control points in the vertex buffer. This basis is not interpolating, thus the curve does in general not go through any of the control points directly. Using this basis, 3 control points can be shared for two continuous neighboring curve segments, e.g., the curves (p_0, p_1, p_2, p_3) and (p_1, p_2, p_3, p_4) are C1 continuous. This feature make this basis a good choice to construct continuous multi-segment curves, as memory consumption can be kept minimal.

OSP_HERMITE It is necessary to have both vertex buffer and tangent buffer for using this basis. The indices point to the first of 2 consecutive points in the vertex buffer, and the first of 2 consecutive tangents in the tangent buffer. This basis is interpolating, thus does exactly go through the first and second control point, and the first order derivative at the begin and end matches exactly the value specified in the tangent buffer. When connecting two segments continuously, the end point and tangent of the previous segment can be shared.

OSP_CATMULL_ROM The indices point to the first of 4 consecutive control points in the vertex buffer. If (p_0, p_1, p_2, p_3) represent the points then this basis goes through p_1 and p_2 , with tangents as $(p_2 - p_0)/2$ and $(p_3 - p_1)/2$.

The following section describes the properties of different curve types’ and how they define the geometry of a curve:

OSP_FLAT This type enables faster rendering as the curve is rendered as a connected sequence of ray facing quads.

OSP_ROUND This type enables rendering a real geometric surface for the curve which allows closeup views. This mode renders a sweep surface by sweeping a varying radius circle tangential along the curve.

OSP_RIBBON The type enables normal orientation of the curve and requires a normal buffer be specified along with vertex buffer. The curve is rendered as a flat band whose center approximately follows the provided vertex buffer and whose normal orientation approximately follows the provided normal buffer. Not supported for basis OSP_LINEAR.

OSP_DISJOINT Only supported for basis OSP_LINEAR; the segments are open and not connected at the joints, i.e., the curve segments are either individual cones or cylinders.

Boxes

OSPRay can directly render axis-aligned bounding boxes without the need to convert them to quads or triangles. To do so create a boxes geometry by calling `ospNewGeometry` with type string “box”.

Table 45: Parameters defining a boxes geometry.

Type	Name	Description
box3f[]	box	<i>data</i> array of boxes

Planes

OSPRay can directly render planes defined by plane equation coefficients in its implicit form $ax + by + cz + d = 0$. By default planes are infinite but their extents can be limited by defining optional bounding boxes. A planes geometry can be created by calling `ospNewGeometry` with type string “plane”.

Table 46: Parameters defining a planes geometry.

Type	Name	Description
vec4f[]	plane.coefficients	<i>data</i> array of plane coefficients (a, b, c, d)
box3f[]	plane.bounds	optional <i>data</i> array of bounding boxes

Isosurfaces

OSPRay can directly render multiple isosurfaces of a volume without first tessellating them. To do so create an isosurfaces geometry by calling `ospNewGeometry` with type string “isosurface”. The appearance information of the surfaces is set through the Geometric Model. Per-isosurface colors can be set by passing per-primitive colors to the Geometric Model, in order of the isosurface array.

Table 47: Parameters defining an isosurfaces geometry.

Type	Name	Description
float	isovalue	single isovalues
float[]	isovalue	<i>data</i> array of isovalues
OSPVolume	volume	handle of the <i>Volume</i> to be isosurfaced

GeometricModels

Geometries are matched with surface appearance information through GeometricModels. These take a geometry, which defines the surface representation, and applies either full-object or per-primitive color and material information. To create a geometric model, call

```
OSPGeometricModel ospNewGeometricModel(OSPGeometry geometry);
```

The passed geometry can be NULL as long as the geometry to be used is passed as a parameter. If both a geometry is specified on object creation and as a parameter, the parameter value is used. If the parameter value is later removed, the geometry object passed on object creation is again used.

Color and material are fetched with the primitive ID of the hit (clamped to the valid range, thus a single color or material is fine), or mapped first via the index array (if present). All parameters are optional, however, some renderers (notably the *path tracer*) require a material to be set. Materials are either handles of OSPMaterial, or indices into the material array on the *renderer*, which allows to build a *world* which can be used by different types of renderers.

An *invertNormals* flag allows to invert (shading) normal vectors of the rendered geometry. That is particularly useful for clipping. By changing normal vectors orientation one can control whether inside or outside of the clipping geometry is being removed. For example, a clipping geometry with normals oriented outside clips everything what's inside.

Table 48: Parameters understood by GeometricModel.

Type	Name	Description
OSPMaterial / uint32	material	optional <i>material</i> applied to the geometry, may be an index into the material parameter on the <i>renderer</i> (if it exists)
vec4f	color	optional color assigned to the geometry (linear RGBA)
OSPMaterial[] / uint32[]	material	optional <i>data</i> array of (per-primitive) materials, may be an index into the material parameter on the <i>renderer</i> (if it exists)
vec4f[]	color	optional <i>data</i> array of (per-primitive) colors (linear RGBA)
uint8[]	index	optional <i>data</i> array of per-primitive indices into color and material
bool	invert-Normals	inverts all shading normals (Ns), default false
OSPGeometry	geometry	optional [geometry] object this model references

Lights

To create a new light source of given type *type* use

```
OSPLight ospNewLight(const char *type);
```

All light sources accept the following parameters:

Table 49: Parameters accepted by all lights.

Type	Name	De- fault	Description
vec3f	color	white	color of the light (linear RGB)
float	intensity	1	intensity of the light (a factor)
uchar	intensityQuantity		OSPIntensityQuantity to set the radiometric quantity represented by intensity. The default value depends on the light source.
bool	visible	true	whether the light can be directly seen

In OSPRay the intensity parameter of a light source can correspond to different types of radiometric quantities. The

type of the value represented by a light's `intensity` parameter is set using `intensityQuantity`, which accepts values from the enum type `OSPIntensityQuantity`. The supported types of `OSPIntensityQuantity` differ between the different light sources (see documentation of each specific light source).

Table 50: Types of radiometric quantities used to interpret a light's `intensity` parameter.

Name	Description
<code>OSP_INTENSITY_QUANTITY_POWER</code>	Overall amount of light energy emitted by the light source into the scene, unit is W
<code>OSP_INTENSITY_QUANTITY_INTENSITY</code>	Total amount of light emitted by the light in a given direction, unit is W/sr
<code>OSP_INTENSITY_QUANTITY_RADIANCE</code>	Amount of light emitted by a point on the light source in a given direction, unit is W/sr/m ²
<code>OSP_INTENSITY_QUANTITY_IRRADIANCE</code>	Amount of light arriving at a surface point, assuming the light is oriented towards to the surface, unit is W/m ²
<code>OSP_INTENSITY_QUANTITY_SCALE</code>	Linear scaling factor for light sources with a built-in quantity (e.g., HDRI, or sunSky).

The following light types are supported by most OSPRay renderers.

Directional Light / Distant Light

The distant light (or traditionally the directional light) is thought to be far away (outside of the scene), thus its light arrives (almost) as parallel rays. It is created by passing the type string “distant” to `ospNewLight`. The distant light supports `OSP_INTENSITY_QUANTITY_RADIANCE` and `OSP_INTENSITY_QUANTITY_IRRADIANCE` (default) as `intensityQuantity` parameter value. In addition to the *general parameters* understood by all lights the distant light supports the following special parameters:

Table 51: Special parameters accepted by the distant light.

Type	Name	Default	Description
<code>vec3f</code>	<code>direction</code>	(0, 0, 1)	main emission direction of the distant light
<code>float</code>	<code>angularDiameter</code>	0	apparent size (angle in degree) of the light

Setting the angular diameter to a value greater than zero will result in soft shadows when the renderer uses stochastic sampling (like the *path tracer*). For instance, the apparent size of the sun is about 0.53°.

Point Light / Sphere Light

The sphere light (or the special case point light) is a light emitting uniformly in all directions from the surface toward the outside. It does not emit any light toward the inside of the sphere. It is created by passing the type string “sphere” to `ospNewLight`. The point light supports `OSP_INTENSITY_QUANTITY_POWER`, `OSP_INTENSITY_QUANTITY_INTENSITY` (default) and `OSP_INTENSITY_QUANTITY_RADIANCE` as `intensityQuantity` parameter value. In addition to the *general parameters* understood by all lights the sphere light supports the following special parameters:

Table 52: Special parameters accepted by the sphere light.

Type	Name	Default	Description
<code>vec3f</code>	<code>position</code>	(0, 0, 0)	the center of the sphere light
<code>float</code>	<code>radius</code>	0	the size of the sphere light

Setting the radius to a value greater than zero will result in soft shadows when the renderer uses stochastic sampling (like the *path tracer*).

Spotlight / Photometric Light

The spotlight is a light emitting into a cone of directions. It is created by passing the type string “spot” to `ospNewLight`. The spotlight supports `OSP_INTENSITY_QUANTITY_POWER`, `OSP_INTENSITY_QUANTITY_INTENSITY` (default) and `OSP_INTENSITY_QUANTITY_RADIANCE` as `intensityQuantity` parameter value. In addition to the *general parameters* understood by all lights the spotlight supports the special parameters listed in the table.

Table 53: Special parameters accepted by the spotlight.

Type	Name	Default	Description
vec3f	position	(0, 0, 0)	the center of the spotlight
vec3f	direction	(0, 0, 1)	main emission direction of the spot
float	openingAngle	180	full opening angle (in degree) of the spot; outside of this cone is no illumination
float	penumbraAngle	5	size (angle in degree) of the “penumbra”, the region between the rim (of the illumination cone) and full intensity of the spot; should be smaller than half of <code>openingAngle</code>
float	radius	0	the size of the spotlight, the radius of a disk with normal direction
float	innerRadius	0	in combination with <code>radius</code> turns the disk into a ring
float[]	intensityDistribution		luminous intensity distribution for photometric lights; can be 2D for asymmetric illumination; values are assumed to be uniformly distributed
vec3f	c0		orientation, i.e., direction of the C0-(half)plane (only needed if illumination via <code>intensityDistribution</code> is asymmetric)

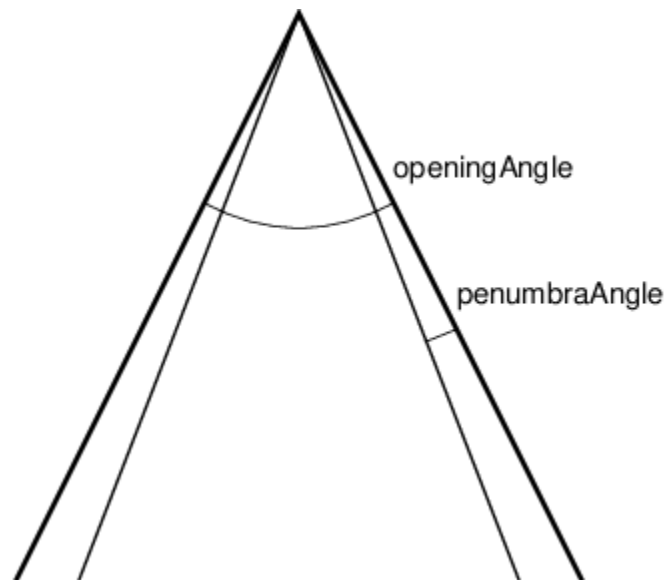

Fig. 5: Angles used by the spotlight.

Setting the radius to a value greater than zero will result in soft shadows when the renderer uses stochastic sampling (like the *path tracer*). Additionally setting the inner radius will result in a ring instead of a disk emitting the light.

Measured light sources (IES, EULUMDAT, ...) are supported by providing an `intensityDistribution` *data* array to modulate the intensity per direction. The mapping is using the C - γ coordinate system (see also below figure): the values of the first (or only) dimension of `intensityDistribution` are uniformly mapped to γ in $[0-\pi]$; the first intensity value to 0, the last value to π , thus at least two values need to be present. If the array has a second dimension then the intensities are not rotational symmetric around `direction`, but are accordingly mapped to the C -halfplanes in $[0-2\pi]$; the first “row” of values to 0 and 2π , the other rows such that they have uniform distance to its neighbors. The orientation of the $C0$ -plane is specified via `c0`. A combination of using an `intensityDistribution` and `OSP_INTENSITY_QUANTITY_POWER` as `intensityQuantity` is not supported at the moment.

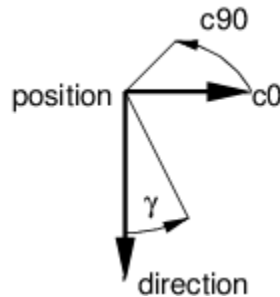

Fig. 6: C - γ coordinate system for the mapping of `intensityDistribution` to the spotlight.

Quad Light

The `quad`³ light is a planar, procedural area light source emitting uniformly on one side into the half-space. It is created by passing the type string “quad” to `ospNewLight`. The quad light supports `OSP_INTENSITY_QUANTITY_POWER`, `OSP_INTENSITY_QUANTITY_INTENSITY` and `OSP_INTENSITY_QUANTITY_RADIANCE` (default) as `intensityQuantity` parameter. In addition to the *general parameters* understood by all lights the quad light supports the following special parameters:

Table 54: Special parameters accepted by the quad light.

Type	Name	Default	Description
vec3f	position	(0, 0, 0)	position of one vertex of the quad light
vec3f	edge1	(1, 0, 0)	vector to one adjacent vertex
vec3f	edge2	(0, 1, 0)	vector to the other adjacent vertex

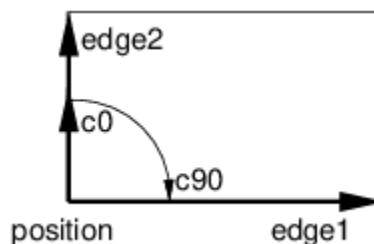

Fig. 7: Defining a quad light which emits toward the reader.

The emission side is determined by the cross product of `edge1` × `edge2`. Note that only renderers that use stochastic sampling (like the path tracer) will compute soft shadows from the quad light. Other renderers will just sample the center of the quad light, which results in hard shadows.

³ actually a parallelogram

Cylinder Light

The cylinder light is a cylindrical, procedural area light source emitting uniformly outwardly into the space beyond the boundary. It is created by passing the type string “cylinder” to `ospNewLight`. The cylinder light supports `OSP_INTENSITY_QUANTITY_POWER`, `OSP_INTENSITY_QUANTITY_INTENSITY` and `OSP_INTENSITY_QUANTITY_RADIANCE` (default) as `intensityQuantity` parameter. In addition to the *general parameters* understood by all lights the cylinder light supports the following special parameters:

Table 55: Special parameters accepted by the cylinder light.

Type	Name	Default	Description
vec3f	position0	(0, 0, 0)	position of the start of the cylinder
vec3f	position1	(0, 0, 1)	position of the end of the cylinder
float	radius	1	radius of the cylinder

Note that only renderers that use stochastic sampling (like the path tracer) will compute soft shadows from the cylinder light. Other renderers will just sample the closest point on the cylinder light, which results in hard shadows.

HDRI Light

The HDRI light is a textured light source surrounding the scene and illuminating it from infinity. It is created by passing the type string “hdri” to `ospNewLight`. The values of the HDRI correspond to radiance and therefore the HDRI light only accepts `OSP_INTENSITY_QUANTITY_SCALE` as `intensityQuantity` parameter value. In addition to the *general parameters* the HDRI light supports the following special parameters:

Table 56: Special parameters accepted by the HDRI light.

Type	Name	De- fault	Description
vec3f	up	(0, 1, 0)	up direction of the light
vec3f	direc- tion	(0, 0, 1)	direction to which the center of the texture will be mapped to (analog to <i>panoramic camera</i>)
OSPTex- ture	map		environment map in latitude / longitude format

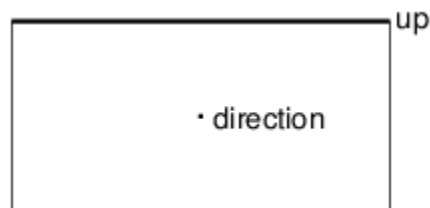

Fig. 8: Orientation and Mapping of an HDRI Light.

Note that the *SciVis renderer* only shows the HDRI light in the background (like an environment map) without computing illumination of the scene.

Ambient Light

The ambient light surrounds the scene and illuminates it from infinity with constant radiance (determined by combining the *parameters* `color` and `intensity` `<#lights>`_``). It is created by passing the type string “ambient” to `ospNewLight`. The ambient light supports `OSP_INTENSITY_QUANTITY_RADIANCE` and `OSP_INTENSITY_QUANTITY_IRRADIANCE` (default) as `intensityQuantity` parameter value.

Note that the *SciVis renderer* uses ambient lights to control the color and intensity of the computed ambient occlusion (AO).

Sun-Sky Light

The sun-sky light is a combination of a distant light for the sun and a procedural hdri light for the sky. It is created by passing the type string “sunSky” to `ospNewLight`. The sun-sky light surrounds the scene and illuminates it from infinity and can be used for rendering outdoor scenes. The radiance values are calculated using the Hošek-Wilkie sky model and solar radiance function. The underlying model of the sun-sky light returns radiance values and therefore the light only accepts `OSP_INTENSITY_QUANTITY_SCALE` as `intensityQuantity` parameter value. To rescale the returned radiance of the sky model the default value for the `intensity` parameter is set to `0.025`. In addition to the *general parameters* the following special parameters are supported:

Table 57: Special parameters accepted by the sunSky light.

Type	Name	Default	Description
vec3f	up	(0, 1, 0)	zenith of sky
vec3f	direction	(0, -1, 0)	main emission direction of the sun
float	turbidity	3	atmospheric turbidity due to particles, in [1–10]
float	albedo	0.3	ground reflectance, in [0–1]
float	horizonEx- tension	0.01	extend the sky dome by stretching the horizon, fraction of the lower hemisphere to cover, in [0–1]

The lowest elevation for the sun is restricted to the horizon.

Note that the *SciVis renderer* only computes illumination from the sun (yet the sky is still shown in the background, like an environment map).

Emissive Objects

The *path tracer* will consider illumination by *geometries* which have a light emitting material assigned (for example the *Luminous* material).

Scene Hierarchy

Groups

Groups in OSPRay represent collections of `GeometricModels`, `VolumetricModels` and `Lights` which share a common local-space coordinate system. To create a group call

```
OSPGroup ospNewGroup();
```

Groups take arrays of geometric models, volumetric models, clipping geometric models and lights, but they are all optional. In other words, there is no need to create empty arrays if there are no geometries, volumes or lights in the group.

By adding `OSPGeometricModels` to the `clippingGeometry` array a clipping geometry feature is enabled. Geometries assigned to this parameter will be used as clipping geometries. Any supported geometry can be used for clipping⁴, the only requirement is that it has to distinctly partition space into clipping and non-clipping one. The use of clipping geometry that is not closed or infinite could result in rendering artifacts. User can decide which part of space is clipped by changing shading normals orientation with the `invertNormals` flag of the *GeometricModel*. All geometries and volumes assigned to `geometry` or `volume` will be clipped. All clipping geometries from all groups and *Instances* will be combined together – a union of these areas will be applied to all other objects in the *world*.

Table 58: Parameters understood by groups.

Type	Name	De- fault	Description
<code>OSPGeometricModel[]</code>	<code>geometry</code>	NULL	<i>data</i> array of <i>GeometricModels</i>
<code>OSPVolumetricModel[]</code>	<code>volume</code>	NULL	<i>data</i> array of <i>VolumetricModels</i>
<code>OSPGeometricModel[]</code>	<code>clippingGeometry</code>	NULL	<i>data</i> array of <i>GeometricModels</i> used for clipping
<code>OSP-Light[]</code>	<code>light</code>	NULL	<i>data</i> array of <i>lights</i>
<code>bool</code>	<code>dynamicScene</code>	false	use <code>RTC_SCENE_DYNAMIC</code> flag (faster BVH build, slower ray traversal), otherwise uses <code>RTC_SCENE_STATIC</code> flag (faster ray traversal, slightly slower BVH build)
<code>bool</code>	<code>compact-Mode</code>	false	tell Embree to use a more compact BVH in memory by trading ray traversal performance
<code>bool</code>	<code>robust-Mode</code>	false	tell Embree to enable more robust ray intersection code paths (slightly slower)

Instances

Instances in `OSPRay` represent a single group’s placement into the world via a transform. To create and instance call

```
OSPInstance ospNewInstance(OSPGroup);
```

⁴ including spheres, boxes, infinite planes, closed meshes, closed subdivisions and curves

Table 59: Parameters understood by instances.

Type	Name	Default	Description
affine3f	transform	identity	world-space transform for all attached geometries and volumes, overridden by <code>motion.*</code> arrays
affine3f[]	motion.transform		uniformly distributed world-space transforms
vec3f[]	motion.scale		uniformly distributed world-space scale, overridden by <code>motion.transform</code>
vec3f[]	motion.pivot		uniformly distributed world-space translation which is applied before <code>motion.rotation</code> (i.e., the rotation center), overridden by <code>motion.transform</code>
quatf[]	motion.rotation		uniformly distributed world-space quaternion rotation, overridden by <code>motion.transform</code>
vec3f[]	motion.translation		uniformly distributed world-space translation, overridden by <code>motion.transform</code>
box1f	time	[0, 1]	time associated with first and last key in <code>motion.*</code> arrays (for motion blur)

World

Worlds are a container of scene data represented by *instances*. To create an (empty) world call

```
OSPWorld ospNewWorld();
```

Objects are placed in the world through an array of instances. Similar to *groups*, the array of instances is optional: there is no need to create empty arrays if there are no instances (though there will be nothing to render).

Applications can query the world (axis-aligned) bounding box after the world has been committed. To get this information, call

```
OSPBounds ospGetBounds(OSPObject);
```

The result is returned in the provided `OSPBounds`⁵ struct:

```
typedef struct {
    float lower[3];
    float upper[3];
} OSPBounds;
```

This call can also take `OSPGROUP` and `OSPINSTANCE` as well: all other object types will return an empty bounding box.

Finally, Worlds can be configured with parameters for making various feature/performance trade-offs (similar to groups).

⁵ `OSPBounds` has essentially the same layout as the `OSP_BOX3F `OSPDataType` <#data>`_`.`

Table 60: Parameters understood by worlds.

Type	Name	Default	Description
OSPInstance[]	instance	NULL	<i>data</i> array with handles of the <i>instances</i>
OSP-Light[]	light	NULL	<i>data</i> array with handles of the <i>lights</i>
bool	dynamic-Scene	false	use RTC_SCENE_DYNAMIC flag (faster BVH build, slower ray traversal), otherwise uses RTC_SCENE_STATIC flag (faster ray traversal, slightly slower BVH build)
bool	compact-Mode	false	tell Embree to use a more compact BVH in memory by trading ray traversal performance
bool	robust-Mode	false	tell Embree to enable more robust ray intersection code paths (slightly slower)

Renderers

A renderer is the central object for rendering in OSPRay. Different renderers implement different features and support different materials. To create a new renderer of given type use

```
OSPRenderer ospNewRenderer(const char *type);
```

General parameters of all renderers are

Table 61: Parameters understood by all renderers.

Type	Name	Default	Description
int	pixelSamples	1	samples per pixel
int	maxPath-Length	20	maximum ray recursion depth
float	minContribution	0.001	sample contributions below this value will be neglected to speedup rendering
float	varianceThreshold	0	threshold for adaptive accumulation
float / vec3f / vec4f	background-Color	black, transparent	background color and alpha (linear A/RGB/RGBA), if no <code>map_backplate</code> is set
OSPTexture	map_backplate		optional <i>texture</i> image used as background (use texture type <code>texture2d</code>)
OSPTexture	map_maxDepth		optional screen-sized float <i>texture</i> with maximum far distance per pixel (use texture type <code>texture2d</code>)
OSPMaterial[]	material		optional <i>data</i> array of <i>materials</i> which can be indexed by a <i>GeometricModel</i> 's <code>material</code> parameter
uchar	pixelFilter	OSP_PIXELFILTER_DEFAULT	OSP_PIXELFILTERType to select the pixel filter used by the renderer for antialiasing. Possible pixel filters are listed below.

OSPRay's renderers support a feature called adaptive accumulation, which accelerates progressive *rendering* by stopping the rendering and refinement of image regions that have an estimated variance below the `varianceThreshold`. This feature requires a *framebuffer* with an `OSP_FB_VARIANCE` channel.

Per default the background of the rendered image will be transparent black, i.e., the alpha channel holds the opacity of the rendered objects. This eases transparency-aware blending of the image with an arbitrary background image by the application. The parameter `backgroundColor` or `map_backplate` can be used to already blend with a constant background color or backplate texture, respectively, (and alpha) during rendering.

OSPRay renderers support depth composition with images of other renderers, for example to incorporate help geometries of a 3D UI that were rendered with OpenGL. The screen-sized *texture* `map_maxDepth` must have format `OSP_TEXTURE_R32F` and flag `OSP_TEXTURE_FILTER_NEAREST`. The fetched values are used to limit the distance of primary rays, thus objects of other renderers can hide objects rendered by OSPRay.

OSPRay supports antialiasing in image space by using pixel filters, which are centered around the center of a pixel. The size w of the filter depends on the selected filter type. The types of supported pixel filters are defined by the `OSP_PIXELFILTER_TYPE` enum and can be set using the `pixelFilter` parameter.

Table 62: Pixel filter types supported by OSPRay for antialiasing in image space.

Name	Description
<code>OSP_PIXELFILTER_POINT</code>	a point filter only samples the center of the pixel, therefore the filter width is $w = 0$
<code>OSP_PIXELFILTER_BOX</code>	a uniform box filter with a width of $w = 1$
<code>OSP_PIXELFILTER_GAUSS</code>	a truncated, smooth Gaussian filter with a standard deviation of $\sigma = 0.5$ and a filter width of $w = 3$
<code>OSP_PIXELFILTER_MITCHELL</code>	the Mitchell-Netravali filter with a width of $w = 4$
<code>OSP_PIXELFILTER_BLACKMAN_HARRIS</code>	the Blackman-Harris filter with a width of $w = 3$

SciVis Renderer

The SciVis renderer is a fast ray tracer for scientific visualization which supports volume rendering and ambient occlusion (AO). It is created by passing the type string “`scivis`” to `ospNewRenderer`. In addition to the *general parameters* understood by all renderers, the SciVis renderer supports the following parameters:

Table 63: Special parameters understood by the SciVis renderer.

Type	Name	De- fault	Description
bool	<code>shadows</code>	false	whether to compute (hard) shadows
int	<code>aoSamples</code>	0	number of rays per sample to compute ambient occlusion
float	<code>aoDistance</code>	10^{20}	maximum distance to consider for ambient occlusion
float	<code>volumeSamplingRate</code>	1	sampling rate for volumes
bool	<code>visibleLights</code>	false	whether light sources are potentially visible (as in the <i>path tracer</i> , regarding each light’s <code>visible</code>)

Note that the intensity (and color) of AO is deduced from an *ambient light* in the `lights` array.⁶ If `aoSamples` is zero (the default) then ambient lights cause ambient illumination (without occlusion).

⁶ If there are multiple ambient lights then their contribution is added.

Ambient Occlusion Renderer

This renderer supports only a subset of the features of the *SciVis renderer* to gain performance. As the name suggest its main shading method is ambient occlusion (AO), *lights* are *not* considered at all and , Volume rendering is supported. The Ambient Occlusion renderer is created by passing the type string “ao” to `ospNewRenderer`. In addition to the *general parameters* understood by all renderers the following parameters are supported as well:

Table 64: Special parameters understood by the Ambient Occlusion renderer.

Type	Name	Default	Description
int	aoSamples	1	number of rays per sample to compute ambient occlusion
float	aoDistance	10 ²⁰	maximum distance to consider for ambient occlusion
float	aoIntensity	1	ambient occlusion strength
float	volumeSamplingRate	1	sampling rate for volumes

Path Tracer

The path tracer supports soft shadows, indirect illumination and realistic materials. This renderer is created by passing the type string “pathtracer” to `ospNewRenderer`. In addition to the *general parameters* understood by all renderers the path tracer supports the following special parameters:

Table 65: Special parameters understood by the path tracer.

Type	Name	De- fault	Description
int	lightSamples	all	number of random light samples per path vertex, per default all light sources are sampled
int	roulettePath- Length	5	ray recursion depth at which to start Russian roulette termination
float	maxContribution	∞	samples are clamped to this value before they are accumulated into the framebuffer
bool	back- groundRefraction	false	allow for alpha blending even if background is seen through refractive objects like glass

The path tracer requires that *materials* are assigned to *geometries*, otherwise surfaces are treated as completely black.

The path tracer supports *volumes* with multiple scattering. The scattering albedo can be specified using the *transfer function*. Extinction is assumed to be spectrally constant.

Materials

Materials describe how light interacts with surfaces, they give objects their distinctive look. To let the given renderer create a new material of given type type call

```
OSPMaterial ospNewMaterial(const char *, const char *material_type);
```

Please note that the first argument is ignored.

The returned handle can then be used to assign the material to a given geometry with

```
void ospSetObject(OSPGeometricModel, "material", OSPMaterial);
```

OBJ Material

The OBJ material is the workhorse material supported by both the *SciVis renderer* and the *path tracer* (the *Ambient Occlusion renderer* only uses the `kd` and `d` parameter). It offers widely used common properties like diffuse and specular reflection and is based on the [MTL material format](#) of Lightwave’s OBJ scene files. To create an OBJ material pass the type string “obj” to `ospNewMaterial`. Its main parameters are

Table 66: Main parameters of the OBJ material.

Type	Name	Default	Description
vec3f	kd	white 0.8	diffuse color (linear RGB)
vec3f	ks	black	specular color (linear RGB)
float	ns	10	shininess (Phong exponent), usually in $[2-10^4]$
float	d	opaque	opacity
vec3f	tf	black	transparency filter color (linear RGB)
OSPTexture	map_bump	NULL	normal map

In particular when using the path tracer it is important to adhere to the principle of energy conservation, i.e., that the amount of light reflected by a surface is not larger than the light arriving. Therefore the path tracer issues a warning and renormalizes the color parameters if the sum of `Kd`, `Ks`, and `Tf` is larger than one in any color channel. Similarly important to mention is that almost all materials of the real world reflect at most only about 80% of the incoming light. So even for a white sheet of paper or white wall paint do better not set `Kd` larger than 0.8; otherwise rendering times are unnecessary long and the contrast in the final images is low (for example, the corners of a white room would hardly be discernible, as can be seen in the figure below).

Fig. 9: Comparison of diffuse rooms with 100% reflecting white paint (left) and realistic 80% reflecting white paint (right), which leads to higher overall contrast. Note that exposure has been adjusted to achieve similar brightness levels.

If present, the color component of *geometries* is also used for the diffuse color `Kd` and the alpha component is also used for the opacity `d`.

Normal mapping can simulate small geometric features via the texture `map_Bump`. The normals n in the normal map are with respect to the local tangential shading coordinate system and are encoded as $(n + 1)$, thus a texel $(0.5, 0.5, 1)$ ⁷ represents the unperturbed shading normal $(0, 0, 1)$. Because of this encoding an sRGB gamma *texture* format is ignored and normals are always fetched as linear from a normal map. Note that the orientation of normal maps is important for a visually consistent look: by convention OSPRay uses a coordinate system with the origin in the lower left corner;

⁷ respectively $(127, 127, 255)$ for 8 bit textures and $(32767, 32767, 65535)$ for 16 bit textures

thus a convexity will look green toward the top of the texture image (see also the example image of a normal map). If this is not the case flip the normal map vertically or invert its green channel.

Fig. 10: Normal map representing an exalted square pyramidal frustum.

Note that Tf colored transparency is implemented in the SciVis and the path tracer but normal mapping with `map_Bump` is currently supported in the path tracer only.

All parameters (except Tf) can be textured by passing a *texture* handle, prefixed with “map_”. The fetched texels are multiplied by the respective parameter value. If only the texture is given (but not the corresponding parameter), only the texture is used (the default value of the parameter is *not* multiplied). The color textures `map_Kd` and `map_Ks` are typically in one of the sRGB gamma encoded formats, whereas textures `map_Ns` and `map_d` are usually in a linear format (and only the first component is used). Additionally, all textures support *texture transformations*.

Fig. 11: Rendering of a OBJ material with wood textures.

Principled

The Principled material is the most complex material offered by the *path tracer*, which is capable of producing a wide variety of materials (e.g., plastic, metal, wood, glass) by combining multiple different layers and lobes. It uses the GGX microfacet distribution with approximate multiple scattering for dielectrics and metals, uses the Oren-Nayar model for diffuse reflection, and is energy conserving. To create a Principled material, pass the type string “principled” to `ospNewMaterial`. Its parameters are listed in the table below.

Table 67: Parameters of the Principled material.

Type	Name	De- fault	Description
vec3f	baseColor	white 0.8	base reflectivity (diffuse and/or metallic, linear RGB)
vec3f	edgeColor	white	edge tint (metallic only, linear RGB)
float	metallic	0	mix between dielectric (diffuse and/or specular) and metallic (specular only with complex IOR) in [0–1]
float	diffuse	1	diffuse reflection weight in [0–1]
float	specular	1	specular reflection/transmission weight in [0–1]
float	ior	1	dielectric index of refraction
float	transmission	0	specular transmission weight in [0–1]
vec3f	transmissionColor	white	attenuated color due to transmission (Beer’s law, linear RGB)
float	transmissionDepth	1	distance at which color attenuation is equal to transmissionColor
float	roughness	0	diffuse and specular roughness in [0–1], 0 is perfectly smooth
float	anisotropy	0	amount of specular anisotropy in [0–1]
float	rotation	0	rotation of the direction of anisotropy in [0–1], 1 is going full circle
float	normal	1	default normal map/scale for all layers
float	baseNormal	1	base normal map/scale (overrides default normal)
bool	thin	false	flag specifying whether the material is thin or solid
float	thickness	1	thickness of the material (thin only), affects the amount of color attenuation due to specular transmission
float	backlight	0	amount of diffuse transmission (thin only) in [0–2], 1 is 50% reflection and 50% transmission, 2 is transmission only
float	coat	0	clear coat layer weight in [0–1]
float	coatIor	1.5	clear coat index of refraction
vec3f	coatColor	white	clear coat color tint (linear RGB)
float	coatThickness	1	clear coat thickness, affects the amount of color attenuation
float	coatRoughness	0	clear coat roughness in [0–1], 0 is perfectly smooth
float	coatNormal	1	clear coat normal map/scale (overrides default normal)
float	sheen	0	sheen layer weight in [0–1]
vec3f	sheenColor	white	sheen color tint (linear RGB)
float	sheenTint	0	how much sheen is tinted from sheenColor toward baseColor
float	sheenRoughness	0.2	sheen roughness in [0–1], 0 is perfectly smooth
float	opacity	1	cut-out opacity/transparency, 1 is fully opaque

All parameters can be textured by passing a *texture* handle, prefixed with “map_” (e.g., “map_baseColor”). *texture transformations* are supported as well.

Fig. 12: Rendering of a Principled coated brushed metal material with textured anisotropic rotation and a dust layer (sheen) on top.

CarPaint

The CarPaint material is a specialized version of the Principled material for rendering different types of car paints. To create a CarPaint material, pass the type string “carPaint” to `ospNewMaterial`. Its parameters are listed in the table below.

Table 68: Parameters of the CarPaint material.

Type	Name	Default	Description
vec3f	baseColor	white 0.8	diffuse base reflectivity (linear RGB)
float	roughness	0	diffuse roughness in [0–1], 0 is perfectly smooth
float	normal	1	normal map/scale
vec3f	flakeColor	Alu- minium	color of metallic flakes (linear RGB)
float	flakeDen- sity	0	density of metallic flakes in [0–1], 0 disables flakes, 1 fully covers the surface with flakes
float	flakeScale	100	scale of the flake structure, higher values increase the amount of flakes
float	flake- Spread	0.3	flake spread in [0–1]
float	flakeJitter	0.75	flake randomness in [0–1]
float	flakeR- oughness	0.3	flake roughness in [0–1], 0 is perfectly smooth
float	coat	1	clear coat layer weight in [0–1]
float	coatIor	1.5	clear coat index of refraction
vec3f	coatColor	white	clear coat color tint (linear RGB)
float	coatThick- ness	1	clear coat thickness, affects the amount of color attenuation
float	coa- tRough- ness	0	clear coat roughness in [0–1], 0 is perfectly smooth
float	coatNor- mal	1	clear coat normal map/scale
vec3f	flipflop- Color	white	reflectivity of coated flakes at grazing angle, used together with coatColor produces a pearlescent paint (linear RGB)
float	flipflop- Falloff	1	flip flop color falloff, 1 disables the flip flop effect

All parameters can be textured by passing a *texture* handle, prefixed with “map_” (e.g., “map_baseColor”). *texture transformations* are supported as well.

Metal

The *path tracer* offers a physical metal, supporting changing roughness and realistic color shifts at edges. To create a Metal material pass the type string “metal” to `ospNewMaterial`. Its parameters are

Table 69: Parameters of the Metal material.

Type	Name	De- fault	Description
vec3f[]	ior	Alu- minium	<i>data</i> array of spectral samples of complex refractive index, each entry in the form (wavelength, eta, k), ordered by wavelength (which is in nm)
vec3f	eta		RGB complex refractive index, real part
vec3f	k		RGB complex refractive index, imaginary part
float	rough- ness	0.1	roughness in [0–1], 0 is perfect mirror

The main appearance (mostly the color) of the Metal material is controlled by the physical parameters `eta` and `k`, the wavelength-dependent, complex index of refraction. These coefficients are quite counter-intuitive but can be found in

Fig. 13: Rendering of a pearlescent CarPaint material.

published measurements. For accuracy the index of refraction can be given as an array of spectral samples in `ior`, each sample a triplet of wavelength (in nm), `eta`, and `k`, ordered monotonically increasing by wavelength; OSPRay will then calculate the Fresnel in the spectral domain. Alternatively, `eta` and `k` can also be specified as approximated RGB coefficients; some examples are given in below table.

Table 70: Index of refraction of selected metals as approximated RGB coefficients, based on data from <https://refractiveindex.info/>.

Metal	eta	k
Ag, Silver	(0.051, 0.043, 0.041)	(5.3, 3.6, 2.3)
Al, Aluminium	(1.5, 0.98, 0.6)	(7.6, 6.6, 5.4)
Au, Gold	(0.07, 0.37, 1.5)	(3.7, 2.3, 1.7)
Cr, Chromium	(3.2, 3.1, 2.3)	(3.3, 3.3, 3.1)
Cu, Copper	(0.1, 0.8, 1.1)	(3.5, 2.5, 2.4)

The `roughness` parameter controls the variation of microfacets and thus how polished the metal will look. The roughness can be modified by a `texture map_roughness` (*texture transformations* are supported as well) to create notable edging effects.

Alloy

The *path tracer* offers an alloy material, which behaves similar to *Metal*, but allows for more intuitive and flexible control of the color. To create an Alloy material pass the type string “alloy” to `ospNewMaterial`. Its parameters are

Table 71: Parameters of the Alloy material.

Type	Name	Default	Description
vec3f	color	white 0.9	reflectivity at normal incidence (0 degree, linear RGB)
vec3f	edgeColor	white	reflectivity at grazing angle (90 degree, linear RGB)
float	roughness	0.1	roughness, in [0–1], 0 is perfect mirror

The main appearance of the Alloy material is controlled by the parameter `color`, while `edgeColor` influences the tint

Fig. 14: Rendering of golden Metal material with textured roughness.

of reflections when seen at grazing angles (for real metals this is always 100% white). If present, the color component of *geometries* is also used for reflectivity at normal incidence color. As in *Metal* the *roughness* parameter controls the variation of microfacets and thus how polished the alloy will look. All parameters can be textured by passing a *texture* handle, prefixed with “map_”; *texture transformations* are supported as well.

Fig. 15: Rendering of a fictional Alloy material with textured color.

Glass

The *path tracer* offers a realistic a glass material, supporting refraction and volumetric attenuation (i.e., the transparency color varies with the geometric thickness). To create a Glass material pass the type string “glass” to `ospNewMaterial`. Its parameters are

Table 72: Parameters of the Glass material.

Type	Name	Default	Description
float	eta	1.5	index of refraction
vec3f	attenuationColor	white	resulting color due to attenuation (linear RGB)
float	attenuationDistance	1	distance affecting attenuation

For convenience, the rather counter-intuitive physical attenuation coefficients will be calculated from the user inputs in such a way, that the `attenuationColor` will be the result when white light traveled trough a glass of thickness `attenuationDistance`.

Fig. 16: Rendering of a Glass material with orange attenuation.

ThinGlass

The *path tracer* offers a thin glass material useful for objects with just a single surface, most prominently windows. It models a thin, transparent slab, i.e., it behaves as if a second, virtual surface is parallel to the real geometric surface. The implementation accounts for multiple internal reflections between the interfaces (including attenuation), but neglects parallax effects due to its (virtual) thickness. To create a such a thin glass material pass the type string “thinGlass” to `ospNewMaterial`. Its parameters are

Table 73: Parameters of the ThinGlass material.

Type	Name	Default	Description
float	eta	1.5	index of refraction
vec3f	attenuationColor	white	resulting color due to attenuation (linear RGB)
float	attenuationDistance	1	distance affecting attenuation
float	thickness	1	virtual thickness

For convenience the attenuation is controlled the same way as with the *Glass* material. Additionally, the color due to attenuation can be modulated with a *texture map_attenuationColor* (*texture transformations* are supported as well). If present, the color component of *geometries* is also used for the attenuation color. The *thickness* parameter sets the (virtual) thickness and allows for easy exchange of parameters with the (real) *Glass* material; internally just the ratio between *attenuationDistance* and *thickness* is used to calculate the resulting attenuation and thus the material appearance.

Fig. 17: Rendering of a ThinGlass material with red attenuation.

Fig. 18: Example image of a colored window made with textured attenuation of the ThinGlass material.

MetallicPaint

The *path tracer* offers a metallic paint material, consisting of a base coat with optional flakes and a clear coat. To create a MetallicPaint material pass the type string “metallicPaint” to `ospNewMaterial`. Its parameters are listed in the table below.

Table 74: Parameters of the MetallicPaint material.

Type	Name	Default	Description
vec3f	baseColor	white 0.8	color of base coat (linear RGB)
float	flakeAmount	0.3	amount of flakes, in [0–1]
vec3f	flakeColor	Aluminium	color of metallic flakes (linear RGB)
float	flakeSpread	0.5	spread of flakes, in [0–1]
float	eta	1.5	index of refraction of clear coat

The color of the base coat `baseColor` can be textured by a *texture* `map_baseColor`, which also supports *texture transformations*. If present, the color component of *geometries* is also used for the color of the base coat. Parameter `flakeAmount` controls the proportion of flakes in the base coat, so when setting it to 1 the `baseColor` will not be visible. The shininess of the metallic component is governed by `flakeSpread`, which controls the variation of the orientation of the flakes, similar to the `roughness` parameter of *Metal*. Note that the effect of the metallic flakes is currently only computed on average, thus individual flakes are not visible.

Fig. 19: Rendering of a MetallicPaint material.

Luminous

The *path tracer* supports the Luminous material which emits light uniformly in all directions and which can thus be used to turn any geometric object into a light source. It is created by passing the type string “luminous” to `ospNewMaterial`. The amount of constant radiance that is emitted is determined by combining the general parameters of lights: ``color and intensity <#lights>`_`` (which essentially means that parameter `intensityQuantity` is not needed because it is always `OSP_INTENSITY_QUANTITY_RADIANCE`).

Table 75: Parameters accepted by the Luminous material.

Type	Name	Default	Description
vec3f	color	white	color of the emitted light (linear RGB)
float	intensity	1	intensity of the light (a factor)
float	transparency	1	material transparency

Fig. 20: Rendering of a yellow Luminous material.

Texture

OSPRay currently implements two texture types (`texture2d` and `volume`) and is open for extension to other types by applications. More types may be added in future releases.

To create a new texture use

```
OSPTexture ospNewTexture(const char *type);
```

Texture2D

The `texture2d` texture type implements an image-based texture, where its parameters are as follows

Table 76: Parameters of `texture2d` texture type.

Type	Name	Description
int	format	OSPTextureFormat for the texture
int	filter	default OSP_TEXTURE_FILTER_BILINEAR, alternatively OSP_TEXTURE_FILTER_NEAREST
OSPData	data	the actual texel 2D <i>data</i>

The supported texture formats for `texture2d` are:

Table 77: Supported texture formats by `texture2d`, i.e., valid constants of type `OSPTextureFormat`.

Name	Description
<code>OSP_TEXTURE_RGBA8</code>	8 bit [0–255] linear components red, green, blue, alpha
<code>OSP_TEXTURE_SRGBA</code>	8 bit sRGB gamma encoded color components, and linear alpha
<code>OSP_TEXTURE_RGBA32F</code>	32 bit float components red, green, blue, alpha
<code>OSP_TEXTURE_RGB8</code>	8 bit [0–255] linear components red, green, blue
<code>OSP_TEXTURE_SRGB</code>	8 bit sRGB gamma encoded components red, green, blue
<code>OSP_TEXTURE_RGB32F</code>	32 bit float components red, green, blue
<code>OSP_TEXTURE_R8</code>	8 bit [0–255] linear single component red
<code>OSP_TEXTURE_RA8</code>	8 bit [0–255] linear two components red, alpha
<code>OSP_TEXTURE_L8</code>	8 bit [0–255] gamma encoded luminance (replicated into red, green, blue)
<code>OSP_TEXTURE_LA8</code>	8 bit [0–255] gamma encoded luminance, and linear alpha
<code>OSP_TEXTURE_R32F</code>	32 bit float single component red
<code>OSP_TEXTURE_RGBA16</code>	16 bit [0–65535] linear components red, green, blue, alpha
<code>OSP_TEXTURE_RGB16</code>	16 bit [0–65535] linear components red, green, blue
<code>OSP_TEXTURE_RA16</code>	16 bit [0–65535] linear two components red, alpha
<code>OSP_TEXTURE_R16</code>	16 bit [0–65535] linear single component red

The size of the texture is inferred from the size of the 2D array data, which also needs have a compatible type to format. The texel data in `data` starts with the texels in the lower left corner of the texture image, like in OpenGL. Per default a texture fetch is filtered by performing bi-linear interpolation of the nearest 2×2 texels; if instead fetching only the nearest texel is desired (i.e., no filtering) then pass the `OSP_TEXTURE_FILTER_NEAREST` flag.

Texturing with `texture2d` image textures requires *geometries* with texture coordinates, e.g., a *mesh* with `vertex.texcoord` provided.

Volume Texture

The volume texture type implements texture lookups based on 3D object coordinates of the surface hit point on the associated geometry. If the given hit point is within the attached volume, the volume is sampled and classified with the transfer function attached to the volume. This implements the ability to visualize volume values (as colored by a transfer function) on arbitrary surfaces inside the volume (as opposed to an isosurface showing a particular value in the volume). Its parameters are as follows

Table 78: Parameters of volume texture type.

Type	Name	Description
<code>OSPVolume</code>	<code>volume</code>	<i>Volume</i> used to generate color lookups
<code>OSPTransferFunction</code>	<code>transferFunction</code>	<i>transfer function</i> applied to volume

`TextureVolume` can be used for implementing slicing of volumes with any geometry type. It enables coloring of the slicing geometry with a different transfer function than that of the sliced volume.

Texture Transformations

All materials with textures also offer to manipulate the placement of these textures with the help of texture transformations. If so, this convention shall be used: the following parameters are prefixed with “texture_name.*”).

Table 79: Parameters to define 2D texture coordinate transformations.

Type	Name	Description
linear2f	transform	linear transformation (rotation, scale)
float	rotation	angle in degree, counterclockwise, around center
vec2f	scale	enlarge texture, relative to center (0.5, 0.5)
vec2f	translation	move texture in positive direction (right/up)

Above parameters are combined into a single `affine2d` transformation matrix and the transformations are applied in the given order. Rotation, scale and translation are interpreted “texture centric”, i.e., their effect seen by an user are relative to the texture (although the transformations are applied to the texture coordinates).

Table 80: Parameter to define 3D volume texture transformations.

Type	Name	Description
affine3f	transform	linear transformation (rotation, scale) plus translation

Similarly, volume texture placement can also be modified by an `affine3f` transformation matrix.

Cameras

To create a new camera of given type `type` use

```
OSPCamera ospNewCamera(const char *type);
```

All cameras accept these parameters:

Table 81: Parameters accepted by all cameras.

Type	Name	Default	Description
vec3f	position	(0, 0, 0)	position of the camera
vec3f	direction	(0, 0, 1)	main viewing direction of the camera
vec3f	up	(0, 1, 0)	up direction of the camera
affine3f	transform	identity	additional world-space transform, overridden by <code>motion.*</code> arrays
float	nearClip	10 ⁻⁶	near clipping distance
vec2f	imageStart	(0, 0)	start of image region (lower left corner)
vec2f	imageEnd	(1, 1)	end of image region (upper right corner)
affine3f[]	motion.transform		additional uniformly distributed world-space transforms
vec3f[]	motion.scale		additional uniformly distributed world-space scale, overridden by <code>motion.transform</code>
vec3f[]	motion.pivot		additional uniformly distributed world-space translation which is applied before <code>motion.rotation</code> (i.e., the rotation center), overridden by <code>motion.transform</code>
quatf[]	motion.rotation		additional uniformly distributed world-space quaternion rotation, overridden by <code>motion.transform</code>
vec3f[]	motion.translation		additional uniformly distributed world-space translation, overridden by <code>motion.transform</code>
box1f	time	[0, 1]	time associated with first and last key in <code>motion.*</code> arrays
box1f	shutter	[0.5, 0.5]	start and end of shutter time (for motion blur), in [0, 1]
uchar	shutterType	OSP_SHUTTER_OPEN	OSP_SHUTTER_* shutterType for motion blur, also allowed are:
			OSP_SHUTTER_ROLLING_RIGHT
			OSP_SHUTTER_ROLLING_LEFT
			OSP_SHUTTER_ROLLING_DOWN
			OSP_SHUTTER_ROLLING_UP
float	rolling-Shutter-Duration	0	for a rolling shutter (see <code>shutterType</code>) the “open” time per line, in [0, <code>shutter.upper-shutter.lower</code>]

The camera is placed and oriented in the world with `position`, `direction` and `up`. Additionally, an extra transformation `transform` can be specified, which will only be applied to 3D vectors (i.e. `position`, `direction` and `up`), but does *not* affect any sizes (e.g., `nearClip`, `apertureRadius`, or `height`). The same holds for the array of transformations `motion.transform` to achieve camera motion blur (in combination with `time` and `shutter`).

OSPRay uses a right-handed coordinate system. The region of the camera sensor that is rendered to the image can be specified in normalized screen-space coordinates with `imageStart` (lower left corner) and `imageEnd` (upper right corner). This can be used, for example, to crop the image, to achieve asymmetrical view frusta, or to horizontally flip the image to view scenes which are specified in a left-handed coordinate system. Note that values outside the default range of [0–1] are valid, which is useful to easily realize overscan or film gate, or to emulate a shifted sensor.

Perspective Camera

The perspective camera implements a simple thin lens camera for perspective rendering, supporting optionally depth of field and stereo rendering (with the *path tracer*). It is created by passing the type string “perspective” to `ospNewCamera`. In addition to the *general parameters* understood by all cameras the perspective camera supports the special parameters listed in the table below.

Table 82: Additional parameters accepted by the perspective camera.

Type	Name	Default	Description
float	fovy	60	the field of view (angle in degree) of the frame’s height
float	aspect	1	ratio of width by height of the frame (and image region)
float	apertureRadius	0	size of the aperture, controls the depth of field
float	focusDistance	1	distance at where the image is sharpest when depth of field is enabled
bool	architectural	false	vertical edges are projected to be parallel
uchar	stereoMode	OSP_STEREO_NONE	OSPstereoMode for stereo rendering, also allowed are:
			OSP_STEREO_LEFT
			OSP_STEREO_RIGHT
			OSP_STEREO_SIDE_BY_SIDE
			OSP_STEREO_TOP_BOTTOM (left eye at top half)
float	interpupillaryDistance	0.0635	distance between left and right eye when stereo is enabled

Note that when computing the aspect ratio a potentially set image region (using `imageStart` & `imageEnd`) needs to be regarded as well.

In architectural photography it is often desired for aesthetic reasons to display the vertical edges of buildings or walls vertically in the image as well, regardless of how the camera is tilted. Enabling the `architectural` mode achieves this by internally leveling the camera parallel to the ground (based on the up direction) and then shifting the lens such that the objects in direction `dir` are centered in the image. If finer control of the lens shift is needed use `imageStart` & `imageEnd`. Because the camera is now effectively leveled its image plane and thus the plane of focus is oriented parallel to the front of buildings, the whole façade appears sharp, as can be seen in the example images below. The resolution of the *framebuffer* is not altered by `imageStart/imageEnd`.

Orthographic Camera

The orthographic camera implements a simple camera with orthographic projection, without support for depth. It is created by passing the type string “orthographic” to `ospNewCamera`. In addition to the *general parameters* understood by all cameras the orthographic camera supports the following special parameters:

Table 83: Additional parameters accepted by the orthographic camera.

Type	Name	Description
float	height	size of the camera’s image plane in y, in world coordinates
float	aspect	ratio of width by height of the frame

For convenience the size of the camera sensor, and thus the extent of the scene that is captured in the image, can be controlled with the `height` parameter. The same effect can be achieved with `imageStart` and `imageEnd`, and both methods can be combined. In any case, the aspect ratio needs to be set accordingly to get an undistorted image.

Fig. 21: Example image created with the perspective camera, featuring depth of field.

Fig. 22: Enabling the architectural flag corrects the perspective projection distortion, resulting in parallel vertical edges.

Fig. 23: Example 3D stereo image using `stereoMode = OSP_STEREO_SIDE_BY_SIDE`.

Fig. 24: Example image created with the orthographic camera.

Panoramic Camera

The panoramic camera implements a simple camera with support for stereo rendering. It captures the complete surrounding with a latitude / longitude mapping and thus the rendered images should best have a ratio of 2:1. A panoramic camera is created by passing the type string “panoramic” to `ospNewCamera`. It is placed and oriented in the scene by using the *general parameters* understood by all cameras.

Table 84: Additional parameters accepted by the panoramic camera.

Type	Name	Description
uchar	stereoMode	OSPstereoMode for stereo rendering, possible values are:
		OSP_STEREO_NONE (default)
		OSP_STEREO_LEFT
		OSP_STEREO_RIGHT
		OSP_STEREO_SIDE_BY_SIDE
		OSP_STEREO_TOP_BOTTOM (left eye at top half)
float	interpupillaryDistance	distance between left and right eye when stereo is enabled, default 0.0635

Fig. 25: Latitude / longitude map created with the panoramic camera.

Picking

To get the world-space position of the geometry (if any) seen at [0–1] normalized screen-space pixel coordinates `screenPos_x` and `screenPos_y` use

```
void ospPick(OSPPickResult *,
    OSPFrameBuffer,
    OSPRenderer,
    OSCamera,
    OSPWorld,
    float screenPos_x,
    float screenPos_y);
```

The result is returned in the provided `OSPPickResult` struct:

```
typedef struct {
    int hasHit;
    float worldPosition[3];
    OSPInstance instance;
    OSPGeometricModel model;
    uint32_t primID;
} OSPPickResult;
```

Note that `ospPick` considers exactly the same camera of the given renderer that is used to render an image, thus matching results can be expected. If the camera supports depth of field then the center of the lens and thus the center of the circle of confusion is used for picking. Note that the caller needs to `ospRelease` the `instance` and `model` handles of `OSPPickResult` once the information is not needed anymore.

Framebuffer

The framebuffer holds the rendered 2D image (and optionally auxiliary information associated with pixels). To create a new framebuffer object of given size `size` (in pixels), color format, and channels use

```
OSPFramebuffer ospNewFramebuffer(int size_x, int size_y,
    OSPFramebufferFormat format = OSP_FB_SRGBA,
    uint32_t framebufferChannels = OSP_FB_COLOR);
```

The parameter `format` describes the format the color buffer has *on the host*, and the format that `ospMapFramebuffer` will eventually return. Valid values are:

Table 85: Supported color formats of the framebuffer that can be passed to `ospNewFramebuffer`, i.e., valid constants of type `OSPFramebufferFormat`.

Name	Description
<code>OSP_FB_NONE</code>	framebuffer will not be mapped by the application
<code>OSP_FB_RGBA8</code>	8 bit [0–255] linear component red, green, blue, alpha
<code>OSP_FB_SRGBA</code>	8 bit sRGB gamma encoded color components, and linear alpha
<code>OSP_FB_RGBA32F</code>	32 bit float components red, green, blue, alpha

The parameter `framebufferChannels` specifies which channels the framebuffer holds, and can be combined together by bitwise OR from the values of `OSPFramebufferChannel` listed in the table below.

Table 86: Framebuffer channels constants (of type `OSPFramebufferChannel`), naming optional information the framebuffer can store. These values can be combined by bitwise OR when passed to `ospNewFramebuffer`.

Name	Description
<code>OSP_FB_COLOR</code>	RGB color including alpha
<code>OSP_FB_DEPTH</code>	euclidean distance to the camera (<i>not</i> to the image plane), as linear 32 bit float; for multiple samples per pixel their minimum is taken
<code>OSP_FB_ACCUM</code>	accumulation buffer for progressive refinement
<code>OSP_FB_VARIANCE</code>	estimation of the current noise level if <code>OSP_FB_ACCUM</code> is also present, see <i>rendering</i>
<code>OSP_FB_NORMAL</code>	accumulated world-space normal of the first non-specular hit, as <code>vec3f</code>
<code>OSP_FB_ALBEDO</code>	accumulated material albedo (color without illumination) at the first hit, as <code>vec3f</code>

If a certain channel value is *not* specified, the given buffer channel will not be present. Note that `OSPRay` makes a clear

distinction between the *external* format of the framebuffer and the internal one: The external format is the format the user specifies in the `format` parameter; it specifies what color format OSPRay will eventually *return* the framebuffer to the application (when calling `ospMapFramebuffer`): no matter what OSPRay uses internally, it will simply return a 2D array of pixels of that format, with possibly all kinds of reformatting, compression/decompression, etc., going on in-between the generation of the *internal* framebuffer and the mapping of the externally visible one.

In particular, `OSP_FB_NONE` is a perfectly valid pixel format for a framebuffer that an application will never map. For example, an application driving a display wall may well generate an intermediate framebuffer and eventually transfer its pixel to the individual displays using an `OSPImageOperation` *image operation*.

The application can map the given channel of a framebuffer – and thus access the stored pixel information – via

```
const void *ospMapFramebuffer(OSPFramebuffer, OSPFramebufferChannel = OSP_FB_COLOR);
```

Note that `OSP_FB_ACCUM` or `OSP_FB_VARIANCE` cannot be mapped. The origin of the screen coordinate system in OSPRay is the lower left corner (as in OpenGL), thus the first pixel addressed by the returned pointer is the lower left pixel of the image.

A previously mapped channel of a framebuffer can be unmapped by passing the received pointer mapped to

```
void ospUnmapFramebuffer(const void *mapped, OSPFramebuffer);
```

The individual channels of a framebuffer can be cleared with

```
void ospResetAccumulation(OSPFramebuffer);
```

This function will clear *all* accumulating buffers (`OSP_FB_VARIANCE`, `OSP_FB_NORMAL`, and `OSP_FB_ALBEDO`, if present) and resets the accumulation counter `accumID`. It is unspecified if the existing color and depth buffers are physically cleared when `ospResetAccumulation` is called.

If `OSP_FB_VARIANCE` is specified, an estimate of the variance of the last accumulated frame can be queried with

```
float ospGetVariance(OSPFramebuffer);
```

Note this value is only updated after synchronizing with `OSP_FRAME_FINISHED`, as further described in *asynchronous rendering*. The estimated variance can be used by the application as a quality indicator and thus to decide whether to stop or to continue progressive rendering.

The framebuffer takes a list of pixel operations to be applied to the image in sequence as an `OSPData`. The pixel operations will be run in the order they are in the array.

Table 87: Parameters accepted by the framebuffer.

Type	Name	Description
<code>OSPImageOperation[]</code>	<code>imageOperation</code>	ordered sequence of image operations

Image Operation

Image operations are functions that are applied to every pixel of a frame. Examples include post-processing, filtering, blending, tone mapping, or sending tiles to a display wall. To create a new pixel operation of given type use

```
OSPImageOperation ospNewImageOperation(const char *type);
```

Tone Mapper

The tone mapper is a pixel operation which implements a generic filmic tone mapping operator. Using the default parameters it approximates the Academy Color Encoding System (ACES). The tone mapper is created by passing the type string “tonemapper” to `ospNewImageOperation`. The tone mapping curve can be customized using the parameters listed in the table below.

Table 88: Parameters accepted by the tone mapper.

Type	Name	Default	Description
float	exposure	1.0	amount of light per unit area
float	contrast	1.6773	contrast (toe of the curve); typically is in [1–2]
float	shoulder	0.9714	highlight compression (shoulder of the curve); typically is in [0.9–1]
float	midIn	0.18	mid-level anchor input; default is 18% gray
float	midOut	0.18	mid-level anchor output; default is 18% gray
float	hdrMax	11.0785	maximum HDR input that is not clipped
bool	acesColor	true	apply the ACES color transforms

To use the popular “Uncharted 2” filmic tone mapping curve instead, set the parameters to the values listed in the table below.

Table 89: Filmic tone mapping curve parameters. Note that the curve includes an exposure bias to match 18% middle gray.

Name	Value
contrast	1.1759
shoulder	0.9746
midIn	0.18
midOut	0.18
hdrMax	6.3704
acesColor	false

Denoiser

OSPRay comes with a module that adds support for Intel® Open Image Denoise. This is provided as an optional module as it creates an additional project dependency at compile time. The module implements a “denoiser” frame operation, which denoises the entire frame before the frame is completed.

Rendering

Asynchronous Rendering

Rendering is by default asynchronous (non-blocking), and is done by combining a framebuffer, renderer, camera, and world.

What to render and how to render it depends on the renderer’s parameters. If the framebuffer supports accumulation (i.e., it was created with `OSP_FB_ACCUM`) then successive calls to `ospRenderFrame` will progressively refine the rendered image.

To start an render task, use

```
OSPFuture ospRenderFrame(OSPFramebuffer, OSPRenderer, OSCamera, OSPWorld);
```

This returns an OSPFuture handle, which can be used to synchronize with the application, cancel, or query for progress of the running task. When ospRenderFrame is called, there is no guarantee when the associated task will begin execution.

Progress of a running frame can be queried with the following API function

```
float ospGetProgress(OSPFuture);
```

This returns the approximated progress of the task in [0-1].

Applications can cancel a currently running asynchronous operation via

```
void ospCancel(OSPFuture);
```

Applications can wait on the result of an asynchronous operation, or choose to only synchronize with a specific event. To synchronize with an OSPFuture use

```
void ospWait(OSPFuture, OSPSyncEvent = OSP_TASK_FINISHED);
```

The following are values which can be synchronized with the application

Table 90: Supported events that can be passed to ospWait.

Name	Description
OSP_NONE_FINISHED	Do not wait for anything to be finished (immediately return from ospWait)
OSP_WORLD_COMMITTED	Wait for the world to be committed (not yet implemented)
OSP_WORLD_RENDERED	Wait for the world to be rendered, but not post-processing operations (Pixel/Tile/Frame Op)
OSP_FRAME_FINISHED	Wait for all rendering operations to complete
OSP_TASK_FINISHED	Wait on full completion of the task associated with the future. The underlying task may involve one or more of the above synchronization events

Currently only rendering can be invoked asynchronously. However, future releases of OSPRay may add more asynchronous versions of API calls (and thus return OSPFuture).

Applications can query whether particular events are complete with

```
int ospIsReady(OSPFuture, OSPSyncEvent = OSP_TASK_FINISHED);
```

As the given running task runs (as tracked by the OSPFuture), applications can query a boolean [0, 1] result if the passed event has been completed.

Applications can query how long an async task ran with

```
float ospGetTaskDuration(OSPFuture);
```

This returns the wall clock execution time of the task in seconds. If the task is still running, this will block until the task is completed. This is useful for applications to query exactly how long an asynchronous task executed without the overhead of measuring both task execution + synchronization by the calling application.

Asynchronously Rendering and ospCommit()

The use of either `ospRenderFrame` or `ospRenderFrameBlocking` requires that all objects in the scene being rendered have been committed before rendering occurs. If a call to `ospCommit()` happens while a frame is rendered, the result is undefined behavior and should be avoided.

Synchronous Rendering

For convenience in certain use cases, `ospray_util.h` provides a synchronous version of `ospRenderFrame`:

```
float ospRenderFrameBlocking(OSPFrameBuffer, OSPRenderer, OSCamera, OSPWorld);
```

This version is the equivalent of:

```
ospRenderFrame
ospWait(f, OSP_TASK_FINISHED)
return ospGetVariance(fb)
```

This version is closest to `ospRenderFrame` from OSPRay v1.x.

Distributed Rendering with MPI

The purpose of the MPI module for OSPRay is to provide distributed rendering capabilities for OSPRay. The module enables image- and data-parallel rendering across HPC clusters using MPI, allowing applications to transparently distribute rendering work, or to render data sets which are too large to fit in memory on a single machine.

The MPI module provides two OSPRay devices to allow applications to leverage distributed rendering capabilities. The `mpiOffload` device provides transparent image-parallel rendering, where the same OSPRay application written for local rendering can be replicated across multiple nodes to distribute the rendering work. The `mpiDistributed` device allows MPI distributed applications to use OSPRay for distributed rendering, where each rank can render an independent piece of a global data set, or hybrid rendering where ranks partially or completely share data.

MPI Offload Rendering

The `mpiOffload` device can be used to distribute image rendering tasks across a cluster without requiring modifications to the application itself. Existing applications using OSPRay for local rendering simply be passed command line arguments to load the module and indicate that the `mpiOffload` device should be used for image-parallel rendering. To load the module, pass `--osp:load-modules=mpi`, to select the `MPIOffloadDevice`, pass `--osp:device=mpiOffload`. For example, the `ospExamples` application can be run as:

```
mpirun -n <N> ./ospExamples --osp:load-modules=mpi --osp:device=mpiOffload
```

and will automatically distribute the image rendering tasks among the corresponding `N` nodes. Note that in this configuration rank 0 will act as a master/application rank, and will run the user application code but not perform rendering locally. Thus, a minimum of 2 ranks are required, one master to run the application and one worker to perform the rendering. Running with 3 ranks for example would now distribute half the image rendering work to rank 1 and half to rank 2.

If more control is required over the placement of ranks to nodes, or you want to run a worker rank on the master node as well you can run the application and the `ospray_mpi_worker` program through MPI's MPMD mode. The `ospray_mpi_worker` will load the MPI module and select the offload device by default.

```
mpirun -n 1 ./ospExamples --osp:load-modules=mpi --osp:device=mpiOffload \
: -n <N> ./ospray_mpi_worker
```

If initializing the `mpiOffload` device manually, or passing parameters through the command line, the following parameters can be set:

Table 91: Parameters specific to the `mpiOffload` Device.

Type	Name	Default	Description
string	<code>mpiMode</code>	<code>mpi</code>	The mode to communicate with the worker ranks. <code>mpi</code> will assume you're launching the application and workers in the same mpi command (or split launch command). <code>mpi</code> is the only supported mode
uint	<code>maxCommandBufferEntries</code>	8192	Set the max number of commands to buffer before submitting the command buffer to the workers
uint	<code>commandBufferSize</code>	512 MiB	Set the max command buffer size to allow. Units are in MiB. Max size is 1.8 GiB
uint	<code>maxInlineDataSize</code>	32 MiB	Set the max size of an <code>OSPData</code> which can be inline'd into the command buffer instead of being sent separately. Max size is half the <code>commandBufferSize</code> . Units are in MiB

The `maxCommandBufferEntries`, `commandBufferSize`, and `maxInlineDataSize` can also be set via the environment variables: `OSPRAY_MPI_MAX_COMMAND_BUFFER_ENTRIES`, `OSPRAY_MPI_COMMAND_BUFFER_SIZE`, and `OSPRAY_MPI_MAX_INLINE_DATA_SIZE`, respectively.

The `mpiOffload` device does not support multiple init/shutdown cycles. Thus, to run `ospBenchmark` for this device make sure to exclude the init/shutdown test by passing `--benchmark_filter=-ospInit_ospShutdown` through the command line.

MPI Distributed Rendering

While MPI Offload rendering is used to transparently distribute rendering work without requiring modification to the application, MPI Distributed rendering is targeted at use of OSPRay within MPI-parallel applications. The MPI distributed device can be selected by loading the `mpi` module, and manually creating and using an instance of the `mpiDistributed` device:

```
ospLoadModule("mpi");

OSPDevice mpiDevice = ospNewDevice("mpiDistributed");
ospDeviceCommit(mpiDevice);
ospSetCurrentDevice(mpiDevice);
```

Your application can either initialize MPI before-hand, ensuring that `MPI_THREAD_SERIALIZED` or higher is supported, or allow the device to initialize MPI on commit. Thread multiple support is required if your application will make MPI calls while rendering asynchronously with OSPRay. When using the distributed device each rank can specify independent local data using the OSPRay API, as if rendering locally. However, when calling `ospRenderFrameAsync` the ranks will work collectively to render the data. The distributed device supports both image-parallel, where the data is replicated, and data-parallel, where the data is distributed, rendering modes. The `mpiDistributed` device will by default use each rank in `MPI_COMM_WORLD` as a render worker; however, it can also take a specific MPI communicator to use as the world communicator. Only those ranks in the specified communicator will participate in rendering.

Table 92: Parameters specific to the distributed `mpiDistributed Device`.

Type	Name	Default	Description
void*	<code>worldCommunicator</code>	<code>MPI_COMM_WORLD</code>	The MPI communicator which the OSPRay workers should treat as their world

Table 93: Parameters specific to the distributed `OSPWorld`.

Type	Name	Default	Description
<code>box3f[]</code>	<code>region</code>	NULL	A list of bounding boxes which bound the owned local data to be rendered by the rank

Table 94: Parameters specific to the `mpiRaycast` renderer.

Type	Name	Default	Description
int	<code>aoSamples</code>	0	The number of AO samples to take per-pixel
float	<code>aoDistance</code>	10^{20}	The AO ray length to use. Note that if the AO ray would have crossed a rank boundary and ghost geometry is not available, there will be visible artifacts in the shading

Image Parallel Rendering in the MPI Distributed Device

If all ranks specify exactly the same data, the distributed device can be used for image-parallel rendering. This works identical to the offload device, except that the MPI-aware application is able to load data in parallel on each rank rather than loading on the master and shipping data out to the workers. When a parallel file system is available, this can improve data load times. Image-parallel rendering is selected by specifying the same data on each rank, and using any of the existing local renderers (e.g., `scivis`, `pathtracer`). See [ospMPIDistribTutorialReplicated](#) for an example.

Data Parallel Rendering in the MPI Distributed Device

The MPI Distributed device also supports data-parallel rendering with sort-last compositing. Each rank can specify a different piece of data, as long as the bounding boxes of each rank's data are non-overlapping. The rest of the scene setup is similar to local rendering; however, for distributed rendering only the `mpiRaycast` renderer is supported. This renderer implements a subset of the `scivis` rendering features which are suitable for implementation in a distributed environment.

By default the aggregate bounding box of the instances in the local world will be used as the bounds of that rank's data. However, when using ghost zones for volume interpolation, geometry or ambient occlusion, each rank's data can overlap. To clip these non-owned overlap regions out a set of regions (the `region` parameter) can pass as a parameter to the `OSPWorld` being rendered. Each rank can specify one or more non-overlapping `box3f`'s which bound the portions of its local data which it is responsible for rendering. See the [ospMPIDistribTutorialVolume](#) for an example.

Finally, the MPI distributed device also supports hybrid-parallel rendering, where multiple ranks can share a single piece of data. For each shared piece of data the rendering work will be assigned image-parallel among the ranks. Partially-shared regions are determined by finding those ranks specifying data with the same bounds (matching regions) and merging them. See the [ospMPIDistribTutorialPartialRepl](#) for an example.

Picking on Distributed Data in the MPI Distributed Device

Calling `ospPick` in the distributed device will find and return the closest global object at the screen position on the rank that owns that object. The other ranks will report no hit. Picking in the distributed device takes into account data clipping applied through the `regions` parameter to avoid picking ghost data.

Interaction with User Modules

The MPI Offload rendering mode trivially supports user modules, with the caveat that attempting to share data directly with the application (e.g., passing a `void*` or other tricks to the module) will not work in a distributed environment. Instead, use the `ospNewSharedData` API to share data from the application with OSPRay, which will in turn be copied over the network to the workers.

The MPI Distributed device also supports user modules, as all that is required for compositing the distributed data are the bounds of each rank's local data.

MultiDevice Rendering

The multidevice module is an experimental OSPRay device type that renders images by delegating off pixel tiles to a number of internal delegate OSPRay devices. Multidevice is still in a development stage and is currently limited to automatically creating ISPCDevice delegates.

If you wish to try it set the `OSPRAY_NUM_SUBDEVICES` environmental variable to the number of subdevices you want to create and tell OSPRay to both load the multidevice extension and create a multidevice for rendering instead of the default ISPCDevice.

One example in a bash like shell is as follows:

```
OSPRAY_NUM_SUBDEVICES=6 ./ospTutorial --osp:load-modules=multidevice --
↳osp:device=multidevice
```

OSPRay Studio

Intel OSPRay Studio is an open source and interactive visualization and ray tracing application that leverages Intel OSPRay as its core rendering engine. It can be used to load complex scenes requiring high fidelity rendering or very large scenes requiring supercomputing resources.

The main control structure is a scene graph which allows users to create an abstract scene in a directed acyclical graph manner. Scenes can either be imported or created using scene graph nodes and structure support. The scenes can then be rendered either with OSPRay's pathtracer or scivis renderer.

More information can be found at the [OSPRay Studio website](#).

OSPRay Plug-in for USD Hydra

The Intel® OSPRay Plug-in for USD Hydra is an open source plugin for Pixar's USD to extend USD's Hydra rendering framework with Intel® OSPRay. The OSPRay for Hydra Plug-in enables interactive scene preview by utilizing OSPRay's high quality renderers and the Intel® Open Image Denoise denoiser.

As part of the oneAPI Rendering Toolkit, OSPRay is highly-optimized for Intel® CPU architectures ranging from laptops to large-scale distributed HPC systems. HdOSPRay leverages the Intel® Rendering Framework to deliver interactive rendering for large-scale models at high levels of fidelity.

More information can be found at the [OSPRay for Hydra Plug-in website](#).

ISPC Implicit SPMD Program Compiler

ISPC is a compiler for a variant of the C programming language, with extensions for "single program, multiple data" (SPMD) programming. Under the SPMD model, the programmer writes a program that generally appears to be a regular serial program, though the execution model is actually that a number of program instances execute in parallel on the hardware.

ISPC compiles a C-based SPMD programming language to run on the SIMD units of CPUs and GPUs; it frequently provides a 3x or more speedup on architectures with 4-wide vector SSE units and 5x-6x on architectures with 8-wide AVX vector units, without any of the difficulty of writing intrinsics code. Parallelization across multiple cores is also supported by ispc, making it possible to write programs that achieve performance improvement that scales by both number of cores and vector unit size.

More information can be found at the [ISPC Implicit SPMD Program Compiler website](#).
