oneAPI is an open, free, and standards-based programming system that provides portability and performance across accelerators and generations of hardware. oneAPI consists of a language and libraries for creating parallel applications:

- *SYCL*: oneAPI's core language for programming accelerators and multiprocessors. SYCL allows developers to reuse code across hardware targets (CPUs and accelerators such as GPUs and FPGAs) and tune for a specific architecture
- *oneDPL*: A companion to the DPC++ Compiler for programming oneAPI devices with APIs from C++ standard library, Parallel STL, and extensions.
- *oneDNN*: High performance implementations of primitives for deep learning frameworks
- *oneCCL*: Communication primitives for scaling deep learning frameworks across multiple devices
- *Level Zero*: System interface for oneAPI languages and libraries
- *oneDAL*: Algorithms for accelerated data science
- *oneTBB*: Library for adding thread-based parallelism to complex applications on multiprocessors
- *oneVPL*: Algorithms for accelerated video processing
- *oneMKL*: High performance math routines for science, engineering, and financial applications
- *Ray Tracing*: A set of advanced ray tracing and high-fidelity rendering and computation routines for use in a wide variety of 3D graphics uses including, film and television photorealistic visual effects and animation rendering, scientific visualization, high-performance computing computations, gaming, and more.

INTRODUCTION

oneAPI simplifies software development by providing the same languages and programming models across accelerator architectures. In this section, we introduce the programming model.

Parallel application development is a combination of *API programming*, where the parallel algorithm is hidden behind an API provided by the system, and *direct programming*, where the application programmer writes the parallel algorithm.

When using API programming, a developer implements performance critical sections of the program with library calls. Well-defined and mature problem domains have high-performance solutions packaged as libraries. oneAPI defines a set of APIs for the most used data parallel domains, and oneAPI platforms provide library implementations across a variety of accelerators. Where possible, the API is based on established standards like BLAS. API programming enables a programmer to attain high performance across a diverse set of accelerators with minimal coding & tuning.

Some problem domains are not well suited to API programming because no standard solution exists or because solutions require a level of customization that cannot be easily implemented in a library. In this case, a developer uses direct programming and must explicitly code the parallel algorithm. oneAPI's programming model is based on data parallelism, where the same computation is performed on each data element, and parallelism of the application scales as the data scales. By allowing the programmer to directly express parallelism, data parallel algorithms make it possible to productively create highly efficient algorithms for parallel architectures.

Data parallel algorithms are used for many of the most computationally demanding problems including scientific computing, artificial intelligence, and visualization. Data parallel algorithms can be efficiently mapped to a diverse set of architectures: multi-core CPUs, GPUs, systolic arrays, and FPGAs.

1.1 Target Audience

The expected audience for this specification includes: application developers, middleware developers, system software providers, and hardware providers. As a *contributor* to this specification, you will shape the accelerator software ecosystem. A productive and high performing system must take into account the constraints at all levels of the software stack. As a *user* of this document, you can ensure that your components will inter-operate with applications and system software for the oneAPI platform.

1.2 Goals of the Specification

oneAPI seeks to provide:

- *Source-level compatibility*: oneAPI applications and middleware port to a conformant oneAPI platform through recompilation and re-tuning.
- *Performance transparency*: API's and language construct allow the programmer enough control over the mapping to hardware to create an efficient solution
- *Software stack portability*: Platform providers can port a oneAPI software stack by implementing the oneAPI Level Zero interface.

1.3 Definitions

This specification uses the definition of must, must not, required, and so on specified in [RFC 2119](#).

1.4 Contribution Guidelines

This specification is a continuation of Intel's decades-long history of working with standards groups and industry/academia initiatives such as The Khronos Group, to create and define specifications in an open and fair process to achieve interoperability and interchangeability. oneAPI is intended to be an open specification and we encourage you to help us make it better. Your feedback is optional, but to enable Intel to incorporate any feedback you may provide to this specification, and to further upstream your feedback to other standards bodies, including The Khronos Group SYCL specification, please submit your feedback under the terms and conditions below. Any contribution of your feedback to the oneAPI Specification does not prohibit you from also contributing your feedback directly to other standard bodies, including The Khronos Group under their respective submission policies.

Contribute to the oneAPI Specification by opening issues in the oneAPI Specification [GitHub repository](#).

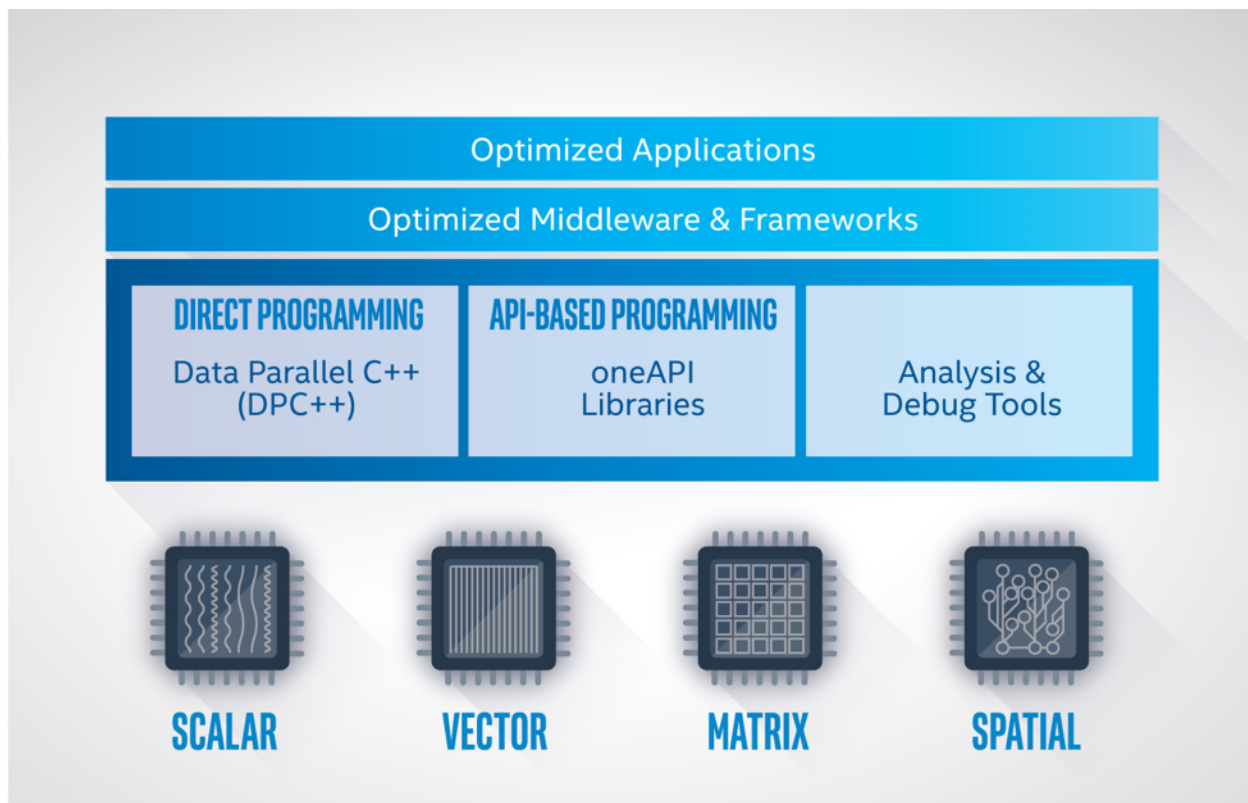

1.4.1 Sign your work

Please include a signed-off-by tag in every contribution of your feedback. By including a signed-off-by tag, you agree that: (a) you have a right to license your feedback to Intel; (b) Intel will be free to use, disclose, reproduce, modify, license, or otherwise distribute your feedback at its sole discretion without any obligations or restrictions of any kind, including without limitation, intellectual property rights or licensing obligations; and (c) your feedback will be public and that a record of your feedback may be maintained indefinitely.

If you agree to the above, every contribution of your feedback must include the following line using your real name and email address: Signed-off-by: Joe Smith joe.smith@email.com

SOFTWARE ARCHITECTURE

oneAPI provides a common developer interface across a range of data parallel accelerators (see the figure below). Programmers use SYCL for both API programming and direct programming. The capabilities of a oneAPI platform are determined by the Level Zero interface, which provides system software a common abstraction for a oneAPI device.

2.1 oneAPI Platform

A oneAPI platform is comprised of a *host* and a collection of *devices*. The host is typically a multi-core CPU, and the devices are one or more GPUs, FPGAs, and other accelerators. The processor serving as the host can also be targeted as a device by the software.

Each device has an associated *command queue*. An application that employs oneAPI runs on the host, following standard C++ execution semantics. To run a *function object* on a device, the application submits a *command group* containing the function object to the device's queue. A function object contains a function definition together with associated variables. A function object submitted to a queue is also referred to as a *data parallel kernel* or simply a *kernel*.

The application running on the host and the functions running on the devices communicate through *memory*. oneAPI defines several mechanisms for sharing memory across the platform, depending on the capabilities of the devices:

Memory Sharing Mechanism	Description
Buffer objects	An application can create <i>buffer objects</i> to pass data to devices. A buffer is an array of data. A command group will define <i>accessor objects</i> to identify which buffers are accessed in this call to the device. The oneAPI runtime will ensure the data in the buffer is accessible to the function running on the device. The buffer-accessor mechanism is available on all oneAPI platforms
Unified addressing	Unified addressing guarantees that the host and all devices will share a unified address space. Pointer values in the unified address space will always refer to the same location in memory.
Unified shared memory	Unified shared memory enables data to be shared through pointers without using buffers and accessors. There are several levels of support for this feature, depending on the capabilities of the underlying device.

The *scheduler* determines when a command group is run on a device. The following mechanisms are used to determine when a command group is ready to run.

- If the buffer-accessor method is used, the command group is ready when the buffers are defined and copied to the device as necessary.
- If an ordered queue is used for a device, the command group is ready as soon as the prior command groups in the queue are finished.
- If unified shared memory is used, you must specify a set of event objects which the command group depends on, and the command group is ready when all of the events are completed.

The application on the host and the functions on the devices can *synchronize* through *events*, which are objects that can coordinate execution. If the buffer-accessor mechanism is used, the application and device can also synchronize through a *host accessor*, through the destruction of a buffer object, or through other more advanced mechanisms.

2.2 API Programming Example

API programming requires the programmer to specify the target device and the memory communication strategy. In the following example, we call the oneMKL matrix multiply routine, GEMM. We are writing in SYCL and omitting irrelevant details.

We create a queue initialized with a *gpu_selector* to specify that we want the computation performed on a GPU, and we define buffers to hold the arrays allocated on the host. Compared to a standard C++ GEMM call, we add a parameter to specify the queue, and we replace the references to the arrays with references to the buffers that contain the arrays. Otherwise this is the standard GEMM C++ interface.

```
using namespace cl::sycl;

// declare host arrays
double *A = new double[M*N];
double *B = new double[N*P];
double *C = new double[M*P];

{
    // Initializing the devices queue with a gpu_selector
    queue q{gpu_selector()};

    // Creating 1D buffers for matrices which are bound to host arrays
    buffer<double, 1> a{A, range<1>{M*N}};
    buffer<double, 1> b{B, range<1>{N*P}};
    buffer<double, 1> c{C, range<1>{M*P}};

    mkl::transpose nT = mkl::transpose::nontrans;
    // Syntax
    // void gemm(queue &exec_queue, transpose transa, transpose transb,
    //           int64_t m, int64_t n, int64_t k, T alpha,
    //           buffer<T,1> &a, int64_t lda,
    //           buffer<T,1> &b, int64_t ldb, T beta,
    //           buffer<T,1> &c, int64_t ldc);
    // call gemm
    mkl::blas::gemm(q, nT, nT, M, P, N, 1.0, a, M, b, N, 0.0, c, M);
}
// when we exit the block, the buffer destructor will write result back to C.
```

2.3 Direct Programming Example

With direct programming, we specify the target device and the memory communication strategy, as we do for API programming. In addition, we must define and submit a command group to perform the computation. In the following example, we write a simple data parallel matrix multiply. We are writing in SYCL and omitting irrelevant details.

We create a queue initialized with a *gpu_selector* to specify that the command group should run on the GPU, and we define buffers to hold the arrays allocated on the host. We then submit the command group to the queue to perform the computation. The command group defines accessors to specify we are reading arrays A and B and writing to C. We then write a C++ lambda to create a function object that computes one element of the resulting matrix multiply. We specify this function object as a parameter to a `parallel_for` which maps the function across the arrays A and B in parallel. When we leave the scope, the destructor for the buffer object holding C writes the data back to the host array.

```

#include <CL/sycl.hpp>
using namespace sycl;

int main() {
    // declare host arrays
    double *Ahost = new double[M*N];
    double *Bhost = new double[N*P];
    double *Chost = new double[M*P];

    {
        // Initializing the devices queue with a gpu_selector
        queue q{gpu_selector()};

        // Creating 2D buffers for matrices which are bound to host arrays
        buffer<double, 2> a{Ahost, range<2>{M,N}};
        buffer<double, 2> b{Bhost, range<2>{N,P}};
        buffer<double, 2> c{Chost, range<2>{M,P}};

        // Submitting command group to queue to compute matrix c=a*b
        q.submit([&](handler &h){
            // Read from a and b, write to c
            auto A = a.get_access<access::mode::read>(h);
            auto B = b.get_access<access::mode::read>(h);
            auto C = c.get_access<access::mode::write>(h);

            int WidthA = a.get_range()[1];

            // Executing kernel
            h.parallel_for(range<2>{M, P},
                [=](id<2> index){
                    int row = index[0];
                    int col = index[1];

                    // Compute the result of one element in c
                    double sum = 0.0;
                    for (int i = 0; i < WidthA; i++) {
                        sum += A[row][i] * B[i][col];
                    }
                    C[index] = sum;
                });
        });
    }
    // when we exit the block, the buffer destructor will write result back to C.
}

```

3.1 Overview

The oneAPI programming language is a combination of SYCL and a set of SYCL extensions that are listed below. The SYCL programming language is based on standard C++ and provides features to define data parallel functions and to launch them on accelerator devices. Unlike some other parallel languages, SYCL allows an application to mix both host code and device code together in the same source file, which provides a more intuitive parallel programming environment.

A conformant oneAPI implementation must implement the [SYCL 2020 Specification](#), which is published by The Khronos Group.

A conformant oneAPI implementation must also implement the set of SYCL extensions listed in the [Extensions Table](#). These extensions provide additional functionality beyond what is specified in the SYCL language. Some of these extensions are required only on certain devices types, as indicated in the table.

Table 1: Table of SYCL Extensions

Extension	CPU	GPU	FPGA
C-CXX-StandardLibrary	Required	Required	Not required ¹
sycl_ext_oneapi_accessor_properties	Required	Required	Required
sycl_ext_oneapi_assert	Required	Required	Required
sycl_ext_oneapi_backend_level_zero	Required ²	Required ²	Required ²
sycl_ext_oneapi_default_context	Required	Required	Required
sycl_ext_oneapi_discard_queue_events	Required	Required	Required
sycl_ext_oneapi_dot_accumulate	Required	Required	Required
sycl_ext_oneapi_enqueue_barrier	Required	Required	Required
sycl_ext_oneapi_filter_selector	Required	Required	Required
sycl_ext_oneapi_local_memory	Required	Required	Required
sycl_ext_oneapi_srgb	Required	Required	Required
sycl_ext_oneapi_sub_group_mask	Required	Required	Required
sycl_ext_oneapi_use_pinned_host_memory_property	Required	Required	Required
sycl_ext_oneapi_usm_device_read_only	Required	Required	Required
sycl_ext_intel_buffer_location	Not required	Not required	Required
sycl_ext_intel_dataflow_pipes	Not required	Not required	Required
sycl_ext_intel_device_info	Required	Required	Required
sycl_ext_intel_fpga_device_selector	Required	Required	Required
sycl_ext_intel_fpga_lsu	Not required	Not required	Required
sycl_ext_intel_fpga_reg	Not required	Not required	Required
sycl_ext_intel_kernel_args_restrict	Required	Required	Required
sycl_ext_intel_mem_channel_property	Not required	Not required	Required
sycl_ext_intel_usm_address_spaces	Required	Required	Required

¹ Likely to be required in the future

² Required if the device backend is Level Zero.

ONEDPL

The oneAPI DPC++ Library (oneDPL) provides the functionality specified in the [C++ standard](#), with extensions to support data parallelism and offloading to devices, and with extensions to simplify its usage for implementing data parallel algorithms.

The library is comprised of the following components:

- *Parallel API*:
 - Parallel algorithms, complemented with execution policies and companion APIs for running on oneAPI devices.
 - An additional set of library classes and functions that are known to be useful in practice but are not yet included into C++ or SYCL specifications.
- *SYCL Kernels API*:
 - A subset of the [C++ standard](#) library which can be used with buffers and data parallel kernels.
 - Support of random number generation including engines and distributions.
 - Various utilities in addition to C++ standard functionality.

4.1 Namespaces

oneDPL uses namespace `oneapi::dpl` and a shorter variant namespace `dpl` for all functionality including parallel algorithms, oneDPL execution policies, etc. For the subset of the standard C++ library for kernels, the standard class and function names are also aliased in namespace `oneapi::dpl`.

oneDPL uses nested namespaces for the functionality aligned with C++ standard. The names of those namespaces are the same as in namespace `std`. For example, oneDPL execution policies are provided in namespace `oneapi::dpl::execution`.

4.2 Parallel API

oneDPL provides the set of algorithms with execution policies as defined by the [C++ Standard](#). All those algorithms work with *C++ Standard aligned execution policies* and with *DPC++ execution policies*.

Additionally, oneDPL provides wrapper functions for [SYCL](#) buffers, special iterators, and a set of non-standard parallel algorithms.

4.2.1 C++ Standard aligned execution policies

oneDPL has the set of execution policies and related utilities that are semantically aligned with the C++ Standard:

```
// Defined in <oneapi/dpl/execution>

namespace oneapi {
  namespace dpl {
    namespace execution {

      class sequenced_policy { /*unspecified*/ };
      class parallel_policy { /*unspecified*/ };
      class parallel_unsequenced_policy { /*unspecified*/ };
      class unsequenced_policy { /*unspecified*/ };

      inline constexpr sequenced_policy seq { /*unspecified*/ };
      inline constexpr parallel_policy par { /*unspecified*/ };
      inline constexpr parallel_unsequenced_policy par_unseq { /*unspecified*/ };
      inline constexpr unsequenced_policy unseq { /*unspecified*/ };

      template <class T>
      struct is_execution_policy;

      template <class T>
      inline constexpr bool is_execution_policy_v = oneapi::dpl::execution::is_execution_
↪policy<T>::value;
    }
  }
}
```

See “Execution policies” in the C++ Standard for more information.

4.2.2 DPC++ Execution Policy

A DPC++ execution policy class `oneapi::dpl::execution::device_policy` specifies where and how an algorithm runs.

```
// Defined in <oneapi/dpl/execution>

namespace oneapi {
  namespace dpl {
    namespace execution {

      template <typename KernelName = /*unspecified*/>
      class device_policy;

      device_policy<> dpcpp_default;

      template <typename KernelName = /*unspecified*/>
      device_policy<KernelName>
      make_device_policy( sycl::queue );

      template <typename KernelName = /*unspecified*/>
```

(continues on next page)

(continued from previous page)

```

device_policy<KernelName>
make_device_policy( sycl::device );

    template <typename NewKernelName, typename OldKernelName>
    device_policy<NewKernelName>
    make_device_policy( const device_policy<OldKernelName>& = dpcpp_default );
    }
}
}

```

dpcpp_default is a predefined execution policy object to run algorithms on the default DPC++ device.

device_policy class

```

template <typename KernelName = /*unspecified*/>
class device_policy
{
public:
    using kernel_name = KernelName;

    device_policy();
    template <typename OtherName>
    device_policy( const device_policy<OtherName>& );
    explicit device_policy( sycl::queue );
    explicit device_policy( sycl::device );

    sycl::queue queue() const;
    operator sycl::queue() const;
};

```

An object of the device_policy type is associated with a sycl::queue that is used to run algorithms on a DPC++ compliant device. When an algorithm runs with device_policy it is capable of processing SYCL buffers (passed via oneapi::dpl::begin/end), data in the host memory and data in Unified Shared Memory (USM), including USM device memory. Data placed in the host memory and USM can only be passed to oneDPL algorithms as pointers and random access iterators. The way to transfer data from the host memory to a device and back is unspecified; per-element data movement to/from a temporary storage is a possible valid implementation.

The KernelName template parameter, also aliased as kernel_name within the class template, is to explicitly provide a name for DPC++ kernels executed by an algorithm the policy is passed to.

```
device_policy()
```

Construct a policy object associated with a queue created with the default device selector.

```
template <typename OtherName>
device_policy( const device_policy<OtherName>& policy )
```

Construct a policy object associated with the same queue as policy, by changing the kernel name of the given policy to kernel_name defined for the new policy.

```
explicit device_policy( sycl::queue queue )
```

Construct a policy object associated with the given queue.

```
explicit device_policy( sycl::device device )
```

Construct a policy object associated with a queue created for the given device.

```
sycl::queue queue() const
```

Return the queue the policy is associated with.

```
operator sycl::queue() const
```

Allow implicit conversion of the policy to a `sycl::queue` object.

make_device_policy function

The `make_device_policy` function templates simplify `device_policy` creation.

```
template <typename KernelName = /*unspecified*/>
device_policy<KernelName>
make_device_policy( sycl::queue queue )
```

Return a policy object associated with `queue`, with a kernel name possibly provided as the template argument, otherwise unspecified.

```
template <typename KernelName = /*unspecified*/>
device_policy<KernelName>
make_device_policy( sycl::device device )
```

Return a policy object to run algorithms on `device`, with a kernel name possibly provided as the template argument, otherwise unspecified.

```
template <typename NewKernelName, typename OldKernelName>
device_policy<NewKernelName>
make_device_policy( const device_policy<OldKernelName>& policy = dpcpp_default )
```

Return a policy object constructed from `policy`, with a new kernel name provided as the template argument. If no policy object is provided, the new policy is constructed from `dpcpp_default`.

4.2.3 Buffer wrappers

```
// Defined in <oneapi/dpl/iterator>

namespace oneapi {
  namespace dpl {

    template < typename T, typename AllocatorT, sycl::access::mode Mode >
    /*unspecified*/ begin( sycl::buffer<T, /*dim=*/1, AllocatorT> buf,
                          sycl::mode_tag_t<Mode> tag = sycl::read_write );

    template < typename T, typename AllocatorT, sycl::access::mode Mode >
    /*unspecified*/ begin( sycl::buffer<T, /*dim=*/1, AllocatorT> buf,
                          sycl::mode_tag_t<Mode> tag, sycl::property::noinit );
```

(continues on next page)

(continued from previous page)

```

template < typename T, typename AllocatorT >
/*unspecified*/ begin( sycl::buffer<T, /*dim=*/1, AllocatorT> buf,
                      sycl::property::noinit );

template < typename T, typename AllocatorT, sycl::access::mode Mode >
/*unspecified*/ end( sycl::buffer<T, /*dim=*/1, AllocatorT> buf,
                    sycl::mode_tag_t<Mode> tag = sycl::read_write );

template < typename T, typename AllocatorT, sycl::access::mode Mode >
/*unspecified*/ end( sycl::buffer<T, /*dim=*/1, AllocatorT> buf,
                    sycl::mode_tag_t<Mode> tag, sycl::property::noinit );

template < typename T, typename AllocatorT >
/*unspecified*/ end( sycl::buffer<T, /*dim=*/1, AllocatorT> buf,
                    sycl::property::noinit );

}
}

```

`oneapi::dpl::begin` and `oneapi::dpl::end` are helper functions for passing DPC++ buffers to oneDPL algorithms. These functions accept a buffer and return an object of an unspecified type that satisfies the following requirements:

- it is CopyConstructible, CopyAssignable, and comparable with operators `==` and `!=`;
- the following expressions are valid: `a + n`, `a - n`, `a - b`, where `a` and `b` are objects of the type, and `n` is an integer value;
- it provides the `get_buffer()` method that returns the buffer passed to the `begin` or `end` function.

When invoking an algorithm, the buffer passed to `begin` should be the same as the buffer passed to `end`. Otherwise, the behavior is undefined.

`sycl::mode_tag_t` and `sycl::property::noinit` parameters allow to specify an access mode to be used for accessing the buffer by algorithms. The mode serves as a hint, and can be overridden depending on semantics of the algorithm. When invoking an algorithm, the same access mode arguments should be used for `begin` and `end`. Otherwise, the behavior is undefined.

```

using namespace oneapi;
auto buf_begin = dpl::begin(buf, sycl::write_only);
auto buf_end_1 = dpl::end(buf, sycl::write_only);
auto buf_end_2 = dpl::end(buf, sycl::write_only, sycl::noinit);
dpl::fill(dpl::dpcpp_default, buf_begin, buf_end_1, 42); // allowed
dpl::fill(dpl::dpcpp_default, buf_begin, buf_end_2, 42); // not allowed

```

4.2.4 Iterators

The oneDPL iterators are defined in the `<oneapi/dpl/iterator>` header, in namespace `oneapi::dpl`.

```

template <typename Integral>
class counting_iterator
{
public:
    using difference_type = /* a signed integer type of the same size as Integral */;
    using value_type = Integral;
    using reference = Integral;

    counting_iterator();
    explicit counting_iterator(Integral init);

    reference operator*() const;
    reference operator[](difference_type i) const;

    difference_type operator-(const counting_iterator& it) const;

    counting_iterator operator+(difference_type forward) const;
    counting_iterator operator-(difference_type backward) const;

    counting_iterator& operator+=(difference_type forward);
    counting_iterator& operator-=(difference_type backward);

    counting_iterator& operator++();
    counting_iterator& operator--();
    counting_iterator& operator++(int);
    counting_iterator& operator--(int);

    bool operator==(const counting_iterator& it) const;
    bool operator!=(const counting_iterator& it) const;
    bool operator<(const counting_iterator& it) const;
    bool operator>(const counting_iterator& it) const;
    bool operator<=(const counting_iterator& it) const;
    bool operator>=(const counting_iterator& it) const;
};

```

`counting_iterator` is a random access iterator-like type that represents an integer counter. When dereferenced, `counting_iterator` provides an `Integral` rvalue equal to the value of the counter; dereference operations cannot be used to modify the counter. The arithmetic and comparison operators of `counting_iterator` behave as if applied to the values of `Integral` type representing the counters of the iterator instances passed to the operators.

```

class discard_iterator
{
public:
    using difference_type = std::ptrdiff_t;
    using value_type = /* unspecified */;
    using reference = /* unspecified */;

    discard_iterator();
    explicit discard_iterator(difference_type init);
};

```

(continues on next page)

(continued from previous page)

```

reference operator*() const;
reference operator[](difference_type) const;

difference_type operator-(const discard_iterator& it) const;

discard_iterator operator+(difference_type forward) const;
discard_iterator operator-(difference_type backward) const;

discard_iterator& operator+=(difference_type forward);
discard_iterator& operator-=(difference_type backward);

discard_iterator& operator++();
discard_iterator& operator--();
discard_iterator operator++(int);
discard_iterator operator--(int);

bool operator==(const discard_iterator& it) const;
bool operator!=(const discard_iterator& it) const;
bool operator<(const discard_iterator& it) const;
bool operator>(const discard_iterator& it) const;
};

```

`discard_iterator` is a random access iterator-like type that, when dereferenced, provides an lvalue that may be assigned an arbitrary value. The assignment has no effect on the `discard_iterator` instance; the write is discarded. The arithmetic and comparison operators of `discard_iterator` behave as if applied to integer counter values maintained by the iterator instances to determine their position relative to each other.

```

template <typename SourceIterator, typename IndexMap>
class permutation_iterator
{
public:
    using difference_type =
        typename std::iterator_traits<SourceIterator>::difference_type;
    using value_type = typename std::iterator_traits<SourceIterator>::value_type;
    using pointer = typename std::iterator_traits<SourceIterator>::pointer;
    using reference = typename std::iterator_traits<SourceIterator>::reference;

    permutation_iterator(const SourceIterator& input1, const IndexMap& input2,
                        std::size_t index = 0);

    SourceIterator base() const;

    reference operator*() const;
    reference operator[](difference_type i) const;

    difference_type operator-(const permutation_iterator& it) const;

    permutation_iterator operator+(difference_type forward) const;
    permutation_iterator operator-(difference_type backward) const;

    permutation_iterator& operator+=(difference_type forward);
    permutation_iterator& operator-=(difference_type forward);
};

```

(continues on next page)

(continued from previous page)

```

permutation_iterator& operator++();
permutation_iterator& operator--();
permutation_iterator operator++(int);
permutation_iterator operator--(int);

bool operator==(const permutation_iterator& it) const;
bool operator!=(const permutation_iterator& it) const;
bool operator<(const permutation_iterator& it) const;
bool operator>(const permutation_iterator& it) const;
bool operator<=(const permutation_iterator& it) const;
bool operator>=(const permutation_iterator& it) const;
};

```

`permutation_iterator` is a random access iterator-like type whose dereferenced value set is defined by the source iterator provided, and whose iteration order over the dereferenced value set is defined by either another iterator or a functor that maps the `permutation_iterator` index to the index of the source iterator. The arithmetic and comparison operators of `permutation_iterator` behave as if applied to integer counter values maintained by the iterator instances to determine their position in the index map.

`permutation_iterator::operator*` uses the counter value of the instance on which it is invoked to index into the index map. The corresponding value in the map is then used to index into the value set defined by the source iterator. The resulting lvalue is returned as the result of the operator.

`permutation_iterator::operator[]` uses the parameter `i` to index into the index map. The corresponding value in the map is then used to index into the value set defined by the source iterator. The resulting lvalue is returned as the result of the operator.

```

template <typename SourceIterator, typename IndexMap>
permutation_iterator<SourceIterator, IndexMap>
make_permutation_iterator(SourceIterator source, IndexMap map);

```

`make_permutation_iterator` constructs and returns an instance of `permutation_iterator` using the source iterator and index map provided.

```

template <typename Iterator, typename UnaryFunc>
class transform_iterator
{
public:
    using difference_type = typename std::iterator_traits<Iterator>::difference_type;
    using reference = typename std::invoke_result<UnaryFunc,
        typename std::iterator_traits<Iterator>::reference>::type;
    using value_type = typename std::remove_reference<reference>::type;
    using pointer = typename std::iterator_traits<Iterator>::pointer;

    Iterator base() const;

    transform_iterator(Iterator it, UnaryFunc unary_func);
    transform_iterator(const transform_iterator& input);
    transform_iterator& operator=(const transform_iterator& input);

    reference operator*() const;
    reference operator[](difference_type i) const;
};

```

(continues on next page)

(continued from previous page)

```

difference_type operator-(const transform_iterator& it) const

transform_iterator operator+(difference_type forward) const;
transform_iterator operator-(difference_type backward) const;

transform_iterator& operator+=(difference_type forward);
transform_iterator& operator-=(difference_type backward);

transform_iterator& operator++();
transform_iterator& operator--();
transform_iterator operator++(int);
transform_iterator operator--(int);

bool operator==(const transform_iterator& it) const;
bool operator!=(const transform_iterator& it) const;
bool operator<(const transform_iterator& it) const;
bool operator>(const transform_iterator& it) const;
bool operator<=(const transform_iterator& it) const;
bool operator>=(const transform_iterator& it) const;
};

```

`transform_iterator` is a random access iterator-like type whose dereferenced value set is defined by the unary function and source iterator provided. When dereferenced, `transform_iterator` provides the result of the unary function applied to the corresponding element of the source iterator; dereference operations cannot be used to modify the elements of the source iterator unless the unary function result includes a reference to the element. The arithmetic and comparison operators of `transform_iterator` behave as if applied to the source iterator itself.

```

template <typename UnaryFunc, typename Iterator>
transform_iterator<UnaryFunc, Iterator>
make_transform_iterator(Iterator, UnaryFunc);

```

`make_transform_iterator` constructs and returns an instance of `transform_iterator` using the source iterator and unary function object provided.

```

template <typename... Iterators>
class zip_iterator
{
public:
    using difference_type = typename std::make_signed<std::size_t>::type;
    using value_type =
        std::tuple<typename std::iterator_traits<Iterators>::value_type...>;
    using reference = /* unspecified tuple of reference types */;
    using pointer =
        std::tuple<typename std::iterator_traits<Iterators>::pointer...>;

    std::tuple<Iterators...> base() const;

    zip_iterator();
    explicit zip_iterator(Iterators... args);
    zip_iterator(const zip_iterator& input);
    zip_iterator& operator=(const zip_iterator& input);
};

```

(continues on next page)

(continued from previous page)

```

reference operator*() const;
reference operator[](difference_type i) const;

difference_type operator-(const zip_iterator& it) const;
zip_iterator operator-(difference_type backward) const;
zip_iterator operator+(difference_type forward) const;

zip_iterator& operator+=(difference_type forward);
zip_iterator& operator-=(difference_type backward);

zip_iterator& operator++();
zip_iterator& operator--();
zip_iterator operator++(int);
zip_iterator operator--(int);

bool operator==(const zip_iterator& it) const;
bool operator!=(const zip_iterator& it) const;
bool operator<(const zip_iterator& it) const;
bool operator>(const zip_iterator& it) const;
bool operator<=(const zip_iterator& it) const;
bool operator>=(const zip_iterator& it) const;
};

```

`zip_iterator` is an iterator-like type defined over one or more iterators. When dereferenced, the value returned from `zip_iterator` is a tuple of the values returned by dereferencing the source iterators over which the `zip_iterator` is defined. The arithmetic operators of `zip_iterator` update the source iterators of a `zip_iterator` instance as though the operation were applied to each of these iterators.

```

template <typename... Iterators>
zip_iterator<Iterators...>
make_zip_iterator(Iterators...);

```

`make_zip_iterator` constructs and returns an instance of `zip_iterator` using the set of source iterators provided.

4.2.5 Parallel Algorithms

The parallel algorithms are defined in the `<oneapi/dpl/algorithm>` header, in namespace `oneapi::dpl`.

```

template<typename Policy, typename InputKeyIt, typename InputValueIt,
        typename OutputValueIt,
        typename T = typename std::iterator_traits<InputValueIt>::value_type,
        typename BinaryPred =
            std::equal_to<typename std::iterator_traits<InputKeyIt>::value_type>,
        typename BinaryOp =
            std::plus<typename std::iterator_traits<InputValueIt>::value_type>>
OutputValueIt
exclusive_scan_by_segment(Policy&& policy, InputKeyIt keys_first,
                        InputKeyIt keys_last, InputValueIt values_first, OutputValueIt values_result,
                        T initial_value = 0,
                        BinaryPred binary_pred =

```

(continues on next page)

(continued from previous page)

```

std::equal_to<typename std::iterator_traits<InputKeyIt>::value_type>(),
BinaryOp binary_op =
std::plus<typename std::iterator_traits<InputValueIt>::value_type>());

```

`oneapi::dpl::exclusive_scan_by_segment` performs partial prefix scans by applying the `binary_op` operation to a sequence of values. Each partial scan applies to a contiguous subsequence determined by the keys associated with the values being equal according to the `binary_pred` predicate, and the first element of each scan is the initial value provided. The return value is an iterator targeting the end of the result sequence.

The initial value used if one is not provided is an instance of the `value_type` of the `InputValueIt` iterator type initialized to 0. If no binary predicate is provided for the comparison of keys an instance of `std::equal_to` with the `value_type` of the `InputKeyIt` iterator type is used. Finally, an instance of `std::plus` with the `value_type` of the `InputValueIt` iterator type is used if no binary operator is provided to combine the elements of the value subsequences.

```

template<typename Policy, typename InputKeyIt, typename InputValueIt,
        typename OutputValueIt,
        typename BinaryPredcate =
            std::equal_to<typename std::iterator_traits<InputKeyIt>::value_type>,
        typename BinaryOp =
            std::plus<typename std::iterator_traits<InputValueIt>::value_type>>
OutputValueIt
inclusive_scan_by_segment(Policy&& policy, InputKeyIt keys_first,
                        InputKeyIt keys_last, InputValueIt values_first, OutputValueIt values_result
                        BinaryPred binary_pred =
                            std::equal_to<typename std::iterator_traits<InputKeyIt>::value_type>(),
                        BinaryOp binary_op =
                            std::plus<typename std::iterator_traits<InputValueIt>::value_type>());

```

`oneapi::dpl::inclusive_scan_by_segment` performs partial prefix scans by applying the `binary_op` operation to a sequence of values. Each partial scan applies to a contiguous subsequence determined by the keys associated with the values being equal according to the `binary_pred` predicate. The return value is an iterator targeting the end of the result sequence.

If no binary predicate is provided for the comparison of keys an instance of `std::equal_to` with the `value_type` of the `InputKeyIt` iterator type is used. An instance of `std::plus` with the `value_type` of the `InputValueIt` iterator type is used if no binary operator is provided to combine the elements of the value subsequences.

```

template<typename Policy, typename InputKeyIt, typename InputValueIt,
        typename OutputKeyIt, typename OutputValueIt,
        typename BinaryPredcate =
            std::equal_to<typename std::iterator_traits<InputKeyIt>::value_type>,
        typename BinaryOp =
            std::plus<typename std::iterator_traits<InputValueIt>::value_type>>
std::pair<OutputKeyIt,OutputValueIt>
reduce_by_segment(Policy&& policy, InputKeyIt keys_first, InputKeyIt keys_last,
                InputValueIt values_first, OutputKeyIt keys_result,
                OutputValueIt values_result,
                BinaryPred binary_pred =
                    std::equal_to<typename std::iterator_traits<InputKeyIt>::value_type>(),
                BinaryOp binary_op =
                    std::plus<typename std::iterator_traits<InputValueIt>::value_type>());

```

`oneapi::dpl::reduce_by_segment` performs partial reductions on a sequence of values. Each reduction is com-

puted with the `binary_op` operation for a contiguous subsequence of values determined by the associated keys being equal according to the `binary_pred` predicate. For each subsequence the first of the equal keys is stored into `keys_result` and the computed reduction is stored into `values_result`. The return value is a pair of iterators holding the end of the resulting sequences.

If no binary predicate is provided for the comparison of keys an instance of `std::equal_to` with the `value_type` of the `InputKeyIt` iterator type is used. An instance of `std::plus` with the `value_type` of the `InputValueIt` iterator type is used to combine the values in each subsequence identified if a binary operator is not provided.

```
template<typename Policy, typename InputIt1, typename InputIt2, typename OutputIt,
        typename Comparator =
            std::less<typename std::iterator_traits<InputIt>::value_type>>
OutputIt
binary_search(Policy&& policy, InputIt1 start, InputIt1 end,
              InputIt2 value_first, InputIt2 value_last, OutputIterator result,
              Comparator comp =
                  std::less<typename std::iterator_traits<InputIt1>::value_type>());
```

`oneapi::dpl::binary_search` performs a binary search over the data in `[start, end)` for each value in `[value_first, value_last)`. If the value exists in the data searched then the corresponding element in `[result, result + distance(value_first, value_last))` is set to true, otherwise it is set to false.

If no comparator is provided, `operator<` is used to determine when the search value is less than an element in the range being searched.

The elements `e` of `[start, end)` must be partitioned with respect to the comparator used. For all elements `e` in `[start, end)` and a given search value `v` in `[value_first, value_last)` `comp(e, v)` implies `!comp(v, e)`.

```
template<typename Policy, typename InputIt1, typename InputIt2, typename OutputIt,
        typename Comparator =
            std::less<typename std::iterator_traits<InputIt>::value_type>>
OutputIt
lower_bound(Policy&& policy, InputIt1 start, InputIt1 end,
            InputIt2 value_first, InputIt2 value_last, OutputIterator result,
            Comparator comp =
                std::less<typename std::iterator_traits<InputIt1>::value_type>());
```

`oneapi::dpl::lower_bound` performs a binary search over the data in `[start, end)` for each value in `[value_first, value_last)` to find the lowest index at which the search value could be inserted in `[start, end)` without violating the ordering defined by the comparator provided. That lowest index is then assigned to the corresponding element in `[result, result + distance(value_first, value_last))`.

If no comparator is provided, `operator<` is used to determine when the search value is less than an element in the range being searched.

The elements `e` of `[start, end)` must be partitioned with respect to the comparator used.

```
template<typename Policy, typename InputIt1, typename InputIt2, typename OutputIt,
        typename Comparator =
            std::less<typename std::iterator_traits<InputIt>::value_type>>
OutputIt
upper_bound(Policy&& policy, InputIt1 start, InputIt1 end,
            InputIt2 value_first, InputIt2 value_last, OutputIterator result,
            Comparator comp =
                std::less<typename std::iterator_traits<InputIt1>::value_type>());
```

`oneapi::dpl::upper_bound` performs a binary search over the data in `[start, end)` for each value in

[value_first, value_last) to find the highest index at which the search value could be inserted in [start, end) without violating the ordering defined by the comparator provided. That highest index is then assigned to the corresponding element in [result, result + distance(value_first, value_last)).

If no comparator is provided, operator< is used to determine when the search value is less than an element in the range being searched.

The elements e of [start, end) must be partitioned with respect to the comparator used.

4.3 SYCL Kernels API

4.3.1 Supported C++ Standard Library APIs and Algorithms

oneDPL defines a subset of the C++ Standard library APIs for use in SYCL kernels. These APIs can be employed in the kernels similarly to how they are employed in code for a typical CPU-based platform.

4.3.2 Random Number Generation

oneDPL provides a subset of the standard C++ pseudo-random number generation functionality suitable to use within SYCL kernels. The APIs are defined in the <oneapi/dpl/random> header.

Supported functionality:

- **Engine class templates:**
 - linear_congruential_engine
 - subtract_with_carry_engine
- **Engine adaptor class templates:**
 - discard_block_engine
- **Engines and engine adaptors with predefined parameters:**
 - minstd_rand0
 - minstd_rand
 - ranlux24_base
 - ranlux48_base
 - ranlux24
 - ranlux48
- **Distribution class templates:**
 - uniform_int_distribution
 - uniform_real_distribtuon
 - normal_distribution
 - exponential_distribution
 - bernoulli_distribution
 - geometric_distribution

- weibull_distribuion
- lognormal_distribution
- cauchy_distribution
- extreme_value_distribution

Additionally, `sycl::vec<>` can be used as the result type for engines, engine adaptors, and distributions.

Limitations:

The following deviations from the [C++ Standard](#) may apply:

- `random_device` and `seed_seq` classes and related APIs in other classes are not required;
- `operator>>()`, `operator<<()`, `operator==()` are not required;
- specifying the size of a random number engine's state is not required;
- distributions are only required to operate with floating point types applicable to supported SYCL devices.

4.3.3 Function Objects

The oneDPL function objects are defined in the `<oneapi/dpl/functional>` header.

```
namespace oneapi {
namespace dpl {
    struct identity
    {
        template <typename T>
        constexpr T&&
        operator()(T&& t) const noexcept;
    };
}
}
```

The `oneapi::dpl::identity` class implements an identity operation. Its function operator receives an instance of a type and returns the argument unchanged.

ONEDNN

oneAPI Deep Neural Network Library (oneDNN) is a performance library containing building blocks for deep learning applications and frameworks. oneDNN supports:

- CNN primitives (Convolutions, Inner product, Pooling, etc.)
- RNN primitives (LSTM, Vanilla, RNN, GRU)
- Normalizations (LRN, Batch, Layer)
- Elementwise operations (ReLU, Tanh, ELU, Abs, etc.)
- Softmax, Sum, Concat, Shuffle
- Reorders from/to optimized data layouts
- 8-bit integer, 16-, 32-bit, and bfloat16 floating point data types

```
// Tensor dimensions
int N, C, H, W;

// User-owned DPC++ objects
sycl::device dev {sycl::gpu_selector {}}; // Device
sycl::context ctx {dev}; // Context
sycl::queue queue {dev}; // Queue
std::vector<sycl::event> dependencies; // Input events dependencies
// Source
float *buf_src = static_cast<float *>(
    sycl::malloc_device((N * C * H * W) * sizeof(float), dev, ctx));
// Results
float *buf_dst = static_cast<float *>(
    sycl::malloc_device((N * C * H * W) * sizeof(float), dev, ctx));

// Create an engine encapsulating users' DPC++ GPU device and context
dnnl::engine engine = dnnl::sycl_interop::make_engine(dev, ctx);
// Create a stream encapsulating users' DPC++ GPU queue
dnnl::stream stream = dnnl::sycl_interop::make_stream(engine, queue);
// Create memory objects that use buf_src and buf_dst as the underlying storage
dnnl::memory mem_src({{N, C, H, W}, dnnl::memory::data_type::f32,
    dnnl::memory::format_tag::nhwc},
    engine, buf_src);
dnnl::memory mem_dst({{N, C, H, W}, dnnl::memory::data_type::f32,
    dnnl::memory::format_tag::nhwc},
    engine, buf_dst);
// Create a ReLU elementwise primitive
```

(continues on next page)

(continued from previous page)

```

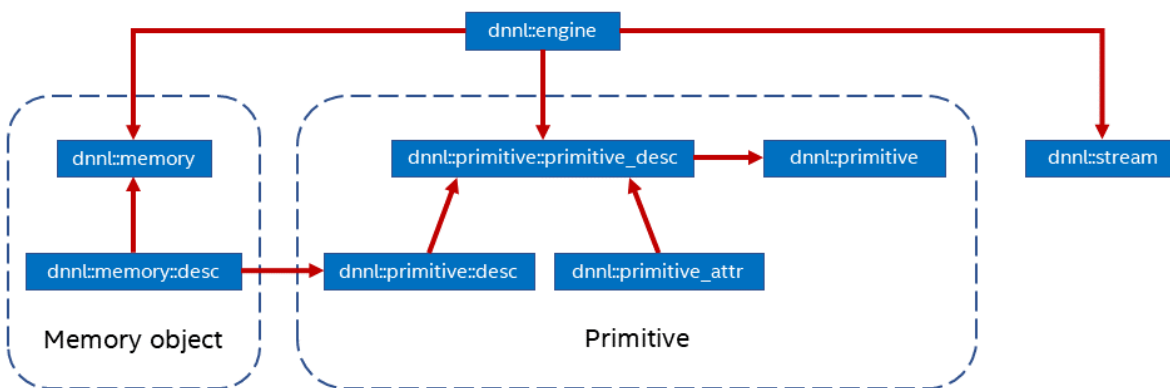

dnnl::eltwise_forward relu {
    {{dnnl::prop_kind::forward_inference, dnnl::algorithm::eltwise_relu,
      mem_src.get_desc(), 0.f, 0.f},
     engine}};
// Execute the ReLU primitive in the stream passing input dependencies and
// retrieving the output dependency
sycl::event event = dnnl::sycl_interop::execute(relu, stream,
    {{DNNL_ARG_SRC, mem_src}, {DNNL_ARG_DST, mem_dst}}, dependencies);

```

5.1 Introduction

Although the origins of this specification are in the existing [open source implementation](#), its goal is to define a *portable* set of APIs. To this end, for example, it intentionally omits implementation-specific details like tiled or blocked memory formats (layouts), and instead describes plain multi-dimensional memory formats and defines opaque *optimized* memory format that can be implementation specific.

oneDNN main concepts are *primitives*, *engines*, *streams*, and *memory objects*.

A *primitive* (`dnnl::primitive`) is a functor object that encapsulates a particular computation such as forward convolution, backward LSTM computations, or a data transformation operation. A single primitive can sometimes represent more complex *fused* computations such as a forward convolution followed by a ReLU. Fusion, among other things, is controlled via the *primitive attributes* mechanism.

The most important difference between a primitive and a pure function is that a primitive can be specialized for a subset of input parameters.

For example, a convolution primitive stores parameters like tensor shapes and can pre-compute other dependent parameters like cache blocking. This approach allows oneDNN primitives to pre-generate code specifically tailored for the requested operation to be performed. The oneDNN programming model assumes that the time it takes to perform the pre-computations is amortized by reusing the same primitive to perform computations multiple times.

A primitive may also need a mutable memory buffer that it may use for temporary storage only during computations. Such buffer is called a scratchpad. It can either be owned by a primitive object (which makes that object non-thread safe) or be an execution-time parameter.

Primitive creation is a potentially expensive operation. Users are expected to create primitives once and reuse them multiple times. Alternatively, implementations may reduce the primitive creation cost by caching primitives that have the same parameters. This optimization falls outside of the scope of this specification.

Engines (`dnnl::engine`) are an abstraction of a computational device: a CPU, a specific GPU card in the system, etc.

Most primitives are created to execute computations on one specific engine. The only exceptions are reorder primitives that may transfer data between two different engines.

Streams (`dnnl::stream`) encapsulate execution context tied to a particular engine. For example, they can correspond to DPC++ command queues.

Memory objects (`dnnl::memory`) encapsulate handles to memory allocated on a specific engine, tensor dimensions, data type, and memory format – the way tensor indices map to offsets in linear memory space. Memory objects are passed to primitives during execution.

Levels of Abstraction

oneDNN has multiple levels of abstractions for primitives and memory objects in order to expose maximum flexibility to its users.

On the logical level, the library provides the following abstractions:

- Memory descriptors (`dnnl::memory::desc`) define the logical dimensions of a tensor, data type, and the format in which the data is laid out in memory. The special format any (`dnnl::memory::format_tag::any`) indicates that the actual format will be defined later.
- Primitive descriptors (`dnnl::primitive_desc_base` is the base class and each of the supported primitives have their own version) can be used to inspect details of a specific primitive implementation like expected memory formats via queries to implement memory format propagation (see *Memory format propagation*) without having to fully instantiate a primitive.

Abstraction level	Memory object	Primitive objects
Logical description	Memory descriptor	Primitive descriptor
Implementation	Memory object	Primitive

5.1.1 Graph Extension

The graph extension is a high level abstraction in oneDNN that allows to work with a computation graph instead of individual primitives. This approach allows to make operation fusion:

- transparent: the integration efforts are reduced by abstracting engine-aware fusion logic.
- scalable: no integration code change is necessary to benefit from new fusion patterns enabled in the oneDNN implementation.

The programming model for the graph extension is detailed in the *graph programming model section*.

5.1.2 General API notes

oneDNN objects can be *empty* in which case they are not valid for any use. Memory descriptors are special in this regard, as their empty versions are regarded as *zero* memory descriptors that can be used to indicate absence of a memory descriptor. Empty objects are usually created using default constructors, but also may be a result of an error during object construction (see the next section).

5.1.3 Error Handling

All oneDNN functions throw the following exception in case of error.

```
struct error : public std::exception
    oneDNN exception class.
```

This class captures the status returned by a failed function call

Additionally, many oneDNN functions that construct or return oneDNN objects have a boolean `allow_empty` parameter that defaults to `false` and that makes the library to return an empty object (a zero object in case of memory descriptors) when an object cannot be constructed instead of throwing an error.

5.1.4 Namespaces

All oneDNN functions and classes reside in `::dnnl` namespace. The functions that accept or return DPC++ objects such as command queues or buffers reside in `::dnnl::sycl_interop` namespace.

Furthermore, oneDNN defines `::oneapi::dnnl` namespace, that is an alias for the `::dnnl` namespace.

5.2 Conventions

oneDNN specification relies on a set of standard naming conventions for variables. This section describes these conventions.

5.2.1 Variable (Tensor) Names

Neural network models consist of operations of the following form:

$$dst = f(src, weights),$$

where `dst` and `src` are activation tensors, and `weights` are learnable tensors.

The backward propagation therefore consists in computing the gradients with respect to the `src` and `weights` respectively:

$$diff_src = df_{src}(diff_dst, src, weights, dst),$$

and

$$diff_weights = df_{weights}(diff_dst, src, weights, dst).$$

While oneDNN uses `src`, `dst`, and `weights` as generic names for the activations and learnable tensors, for a specific operation there might be commonly used and widely known specific names for these tensors. For instance, the *convolution* operation has a learnable tensor called *bias*. For usability reasons, oneDNN primitives use such names in initialization and other functions.

oneDNN uses the following commonly used notations for tensors:

Name	Meaning
src	Source tensor
dst	Destination tensor
weights	Weights tensor
bias	Bias tensor (used in <i>convolution</i> , <i>inner product</i> and other primitives)
scale_shift	Scale and shift tensors (used in <i>Batch Normalization</i> and <i>Layer normalization</i> primitives)
workspace	Workspace tensor that carries additional information from the forward propagation to the backward propagation
scratchpad	Temporary tensor that is required to store the intermediate results
diff_src	Gradient tensor with respect to the source
diff_dst	Gradient tensor with respect to the destination
diff_weights	Gradient tensor with respect to the weights
diff_bias	Gradient tensor with respect to the bias
diff_scale	Gradient tensor with respect to the scale
diff_shift	Gradient tensor with respect to the shift
*_layer	RNN layer data or weights tensors
*_iter	RNN recurrent data or weights tensors

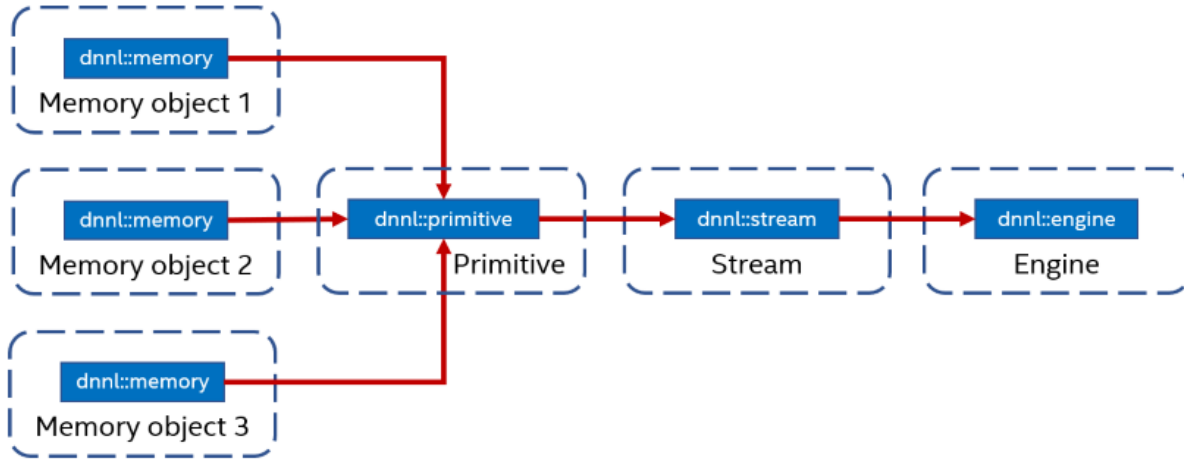

5.2.2 RNN-Specific Notation

The following notations are used when describing RNN primitives.

Name	Semantics
\cdot	matrix multiply operator
$*$	elementwise multiplication operator
W	input weights
U	recurrent weights
\square^T	transposition
B	bias
h	hidden state
a	intermediate value
x	input
\square_t	timestamp index
\square_l	layer index
activation	tanh, relu, logistic
c	cell state
\tilde{c}	candidate state
i	input gate
f	forget gate
o	output gate
u	update gate
r	reset gate

5.3 Execution Model

To execute a primitive, a user needs to pass memory arguments and a stream to the `dnnl::primitive::execute()` member function.

The primitive's computations are executed on the computational device corresponding to the engine on which the primitive (and memory arguments) were created and happens within the context of the stream.

5.3.1 Engine

Engine is abstraction of a computational device: a CPU, a specific GPU card in the system, etc. Most primitives are created to execute computations on one specific engine. The only exceptions are reorder primitives that transfer data between two different engines.

Engines correspond to and can be constructed from pairs of the DPC++ `sycl::device` and `sycl::context` objects. Alternatively, oneDNN itself can create and own the corresponding objects.

```
struct dnnl::engine
    An execution engine.
```

Public Types

```
enum class kind
    Kinds of engines.
```

Values:

```
enumerator any
    An unspecified engine.
```

```
enumerator cpu
    CPU engine.
```

```
enumerator gpu
    GPU engine.
```

Public Functions

engine() = default

Constructs an empty engine. An empty engine cannot be used in any operations.

engine(*kind* akind, size_t index)

Constructs an engine.

Parameters

- **akind** – The kind of engine to construct.
- **index** – The index of the engine. Must be less than the value returned by *get_count()* for this particular kind of engine.

kind **get_kind()** const

Returns the kind of the engine.

Returns The kind of the engine.

Public Static Functions

static size_t **get_count**(*kind* akind)

Returns the number of engines of a certain kind.

Parameters **akind** – The kind of engines to count.

Returns The number of engines of the specified kind.

engine dnnl::sycl_interop::**make_engine**(const cl::sycl::device &adevice, const cl::sycl::context &acontext)

Creates an engine object using a specified SYCL device and SYCL context objects.

Parameters

- **adevice** – SYCL device.
- **acontext** – SYCL context.

Returns Engine object for the adevice SYCL device, within the specified acontext SYCL context.

cl::sycl::device dnnl::sycl_interop::**get_device**(const *engine* &aengine)

Returns the SYCL device underlying a specified engine object.

Parameters **aengine** – Engine object.

Returns SYCL device object underlying the aengine engine object.

cl::sycl::context dnnl::sycl_interop::**get_context**(const *engine* &aengine)

Returns the SYCL context underlying a specified engine object.

Parameters **aengine** – Engine object.

Returns SYCL context object underlying the aengine engine object.

5.3.2 Stream

A *stream* is an encapsulation of execution context tied to a particular engine. They are passed to `dnnl::primitive::execute()` when executing a primitive.

Streams correspond to and can be constructed from DPC++ `sycl::queue` objects. Alternatively, oneDNN itself can create and own the corresponding objects. Streams are considered to be ephemeral and can be created / destroyed as long these operation do not violate DPC++ synchronization requirements.

Similar to DPC++ queues, streams can be in-order and out-of-order (see the relevant portion of the DPC++ specification for the explanation). The desired behavior can be specified using `dnnl::stream::flags` value. A stream created from a DPC++ queue inherits its behavior.

```
struct dnnl::stream
    An execution stream.
```

Public Types

```
enum class flags : unsigned
    Stream flags. Can be combined using the bitwise OR operator.
```

Values:

```
enumerator in_order
    In-order execution.
```

```
enumerator out_of_order
    Out-of-order execution.
```

```
enumerator default_flags
    Default stream configuration.
```

Public Functions

```
stream()
    Constructs an empty stream. An empty stream cannot be used in any operations.
```

```
stream(const engine &engine, flags aflags = flags::default_flags)
    Constructs a stream for the specified engine and with behavior controlled by the specified flags.
```

Parameters

- **aengine** – Engine to create the stream on.
- **aflags** – Flags controlling stream behavior.

```
engine get_engine() const
```

Returns The associated engine.

```
stream &wait()
    Waits for all primitives executing in the stream to finish.
```

Returns The stream itself.

`stream dnnl::sycl_interop::make_stream(const engine &aengine, cl::sycl::queue &aqueue)`
Creates a stream for a specified engine and SYCL queue objects.

Parameters

- **aengine** – Engine object to use for the stream.
- **aqueue** – SYCL queue to use for the stream.

Returns Stream object for the `aengine` engine object, which holds the `aqueue` SYCL queue object.

`cl::sycl::queue dnnl::sycl_interop::get_queue(const stream &astream)`
Returns the SYCL queue underlying a specified stream object.

Parameters `astream` – Stream object.

Returns SYCL queue underlying the `astream` stream object.

5.4 Data model

Data in oneDNN is stored in *memory objects* that both store and describe data that can be of various types and be stored in different formats (layouts).

5.4.1 Data types

oneDNN supports multiple data types. However, the 32-bit IEEE single-precision floating-point data type is the fundamental type in oneDNN. It is the only data type that must be supported by an implementation. All the other types discussed below are optional.

Primitives operating on the single-precision floating-point data type consume data, produce, and store intermediate results using the same data type.

Moreover, single-precision floating-point data type is often used for intermediate results in the mixed precision computations because it provides better accuracy. For example, the elementwise primitive and elementwise post-ops always use it internally.

Note: Implicit downconversion can be enabled in order to speedup computations, and are controlled using the *fpmath mode controls*

oneDNN uses the following enumeration to refer to data types it supports:

enum class `dnnl::memory::data_type`
Data type specification.

Values:

enumerator `undef`
Undefined data type (used for empty memory descriptors).

enumerator `f16`
16-bit/half-precision floating point.

enumerator `bf16`
non-standard 16-bit floating point with 7-bit mantissa.

enumerator **f32**
32-bit/single-precision floating point.

enumerator **s32**
32-bit signed integer.

enumerator **s8**
8-bit signed integer.

enumerator **u8**
8-bit unsigned integer.

oneDNN supports training and inference with the following data types:

Usage mode	Data types
inference	<code>dnnl::memory::data_type::f32</code> , <code>dnnl::memory::data_type::bf16</code> , <code>dnnl::memory::data_type::f16</code> , <code>dnnl::memory::data_type::s8/dnnl::memory::data_type::u8</code>
training	<code>dnnl::memory::data_type::f32</code> , <code>dnnl::memory::data_type::bf16</code>

Note: Using lower precision arithmetic may require changes in the deep learning model implementation.

Individual primitives may have additional limitations with respect to data type support based on the precision requirements. The list of data types supported by each primitive is included in the corresponding sections of the specification guide.

Bfloat16

Note: In this section we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Bfloat16 (`bf16`) is a 16-bit floating point data type based on the IEEE 32-bit single-precision floating point data type (`f32`).

Both `bf16` and `f32` have an 8-bit exponent. However, while `f32` has a 23-bit mantissa, `bf16` has only a 7-bit one, keeping only the most significant bits. As a result, while these data types support a very close numerical range of values, `bf16` has a significantly reduced precision. Therefore, `bf16` occupies a spot between `f32` and the IEEE 16-bit half-precision floating point data type, `f16`. Compared directly to `f16`, which has a 5-bit exponent and a 10-bit mantissa, `bf16` trades increased range for reduced precision.

More details of the bfloat16 data type can be found [here](#).

One of the advantages of using *bf16* versus *f32* is reduced memory footprint and, hence, increased memory access throughput.

Workflow

The main difference between implementing training with the *f32* data type and with the *bf16* data type is the way the weights updates are treated. With the *f32* data type, the weights gradients have the same data type as the weights themselves. This is not necessarily the case with the *bf16* data type as oneDNN allows some flexibility here. For example, one could maintain a master copy of all the weights, computing weights gradients in *f32* and converting the result to *bf16* afterwards.

Support

Most of the primitives can support the *bf16* data type for source and weights tensors. Destination tensors can be specified to have either the *bf16* or *f32* data type. The latter is intended for cases in which the output is to be fed to operations that do not support bfloat16 or require higher precision.

Int8

To push higher performance during inference computations, recent work has focused on computations that use activations and weights stored at lower precision to achieve higher throughput. Int8 computations offer improved performance over higher-precision types because they enable packing more computations into a single instruction, at the cost of reduced (but acceptable) accuracy.

Workflow

oneDNN support symmetric and asymmetric quantization models.

Quantization Model

For each int8 tensor, the oneDNN library allows to specify scaling factors and zero-points (also referred to as quantization parameters), and assumes the following mathematical relationship:

$$x_{f32}[:] = scale_x \cdot (x_{int8}[:] - zp_x)$$

where $scale_x$ is a *scaling factor* in float format, zp_x is the zero point in int32 format, and $[:]$ is used to denote element-wise application of the formula to the arrays. In order to provide best performance, oneDNN does not compute those scaling factors and zero-points as part of primitive computation. Those should be provided by the user through the *attribute mechanism*.

These quantization parameters can either be computed ahead of time using calibration tools (*static* quantization) or at runtime based on the actual minimum and maximum values of a tensor (*dynamic* quantization). Either method can be used in conjunction with oneDNN, as the quantization parameters are passed to the oneDNN primitives at execution time.

To support int8 quantization, primitives should be created and executed as follow:

- during primitive creation, if one or multiple inputs are int8 (signed or not), then the primitive will behave as a quantized integer operation.

- still during primitive creation, the dimensionality of the scaling factors and zero-point should be provided using masks (e.g. one scale per tensor, one scale per channel, ...).
- finally, during primitive execution, the user must provide the actual quantization parameters as arguments to the execute function. Scales shall be f32 values, and zero-points shall be int32 values.

Note: For performance reasons, each primitive implementation can support only a subset of quantization parameter masks. For example, convolution typically supports per-channel scales (no zero-point) for weights, and per-tensor scaling factor and zero-point for activation.

Note: Some primitives might use quantization parameters in order to dequantize/quantize intermediate values. This is for example the case for the *RNN* primitive, which will dequantize before applying non linear functions, and will requantize before executing matrix multiplication operations.

Numerical behavior

Primitive implementations are allowed to convert int8 inputs to wider datatypes (e.g. int16 or int32), as those conversions do not impact accuracy.

During execution, primitives should avoid integer overflows and maintain integer accuracy by using wider datatypes (e.g. int32) for intermediate values and accumulators. Those are then converted as necessary before the result is written to the output memory objects. During that conversion, the behavior in case of underflow/overflow is undefined (e.g. when converting s32 to int8). However, it is highly encouraged for implementations to saturate values.

When multiple operations are fused in a single primitive using the *post-op mechanism*, those are assumed to be computed in f32 precision. As a result the destination quantization parameters are applied after the post-ops as follow:

$$\text{dst}[:,] = \text{post_ops}(\text{OP}(\text{src}[:,], \text{weights}[:,], \dots)) / \text{scale}_{\text{dst}} + \text{zp}_{\text{dst}}$$

Quantizing/dequantizing values between post-operations can still be achieved using one of *eltwise post-ops*, *binary post-ops*, or the scale parameter of the appropriate post-operation.

Example: Convolution Quantization Workflow

Consider a convolution without bias. The tensors are represented as:

- $\text{src}_{f32}[:,] = \text{scale}_{\text{src}} \cdot (\text{src}_{\text{int8}}[:,] - \text{zp}_{\text{src}})$
- $\text{weights}_{f32}[:,] = \text{scale}_{\text{weights}} \cdot \text{weights}_{\text{int8}}[:,]$
- $\text{dst}_{f32}[:,] = \text{scale}_{\text{dst}} \cdot (\text{dst}_{\text{int8}}[:,] - \text{zp}_{\text{dst}})$

Here the src_{f32} , weights_{f32} , dst_{f32} are not computed at all, the whole work happens with int8 tensors. So the task is to compute the dst_{int8} tensor, using the src_{int8} , $\text{weights}_{\text{int8}}$ tensors passed at execution time, as well as the corresponding quantization parameters $\text{scale}_{\text{src}}$, $\text{scale}_{\text{weights}}$, $\text{scale}_{\text{dst}}$ and $\text{zero_point}_{\text{src}}$, $\text{zero_point}_{\text{dst}}$. Mathematically, the computations are:

$$\text{dst}_{\text{int8}}[:,] = \text{f32_to_int8}(\text{scale}_{\text{src}} \cdot \text{scale}_{\text{weights}} \cdot \text{s32_to_f32}(\text{conv}_{\text{s32}}(\text{src}_{\text{int8}}, \text{weights}_{\text{int8}}) - \text{zp}_{\text{src}} \cdot \text{comp}_{\text{s32}}) / \text{scale}_{\text{dst}} + \text{zp}_{\text{dst}})$$

where

- conv_{s32} is just a regular convolution which takes source and weights with int8 data type and compute the result in int32 data type (int32 is chosen to avoid overflows during the computations);

- $comp_{s32}$ is a compensation term to account for src non-zero zero point. This term is computed by the oneDNN library and can typically be pre-computed ahead of time, for example during weights reorder.
- $f32_to_s8()$ converts an $f32$ value to $s8$ with potential saturation if the values are out of the range of the $int8$ data type.
- $s32_to_f32()$ converts an $int8$ value to $f32$ with potential rounding. This conversion is typically necessary to apply $f32$ scaling factors.

Per-Channel Scaling

Primitives may have limited support of multiple scales for a quantized tensor. The most popular use case is the *Convolution and Deconvolution* primitives that support per-output-channel scaling factors for the weights, meaning that the actual convolution computations would need to scale different output channels differently.

- $src_{f32}(n, ic, ih, iw) = scale_{src} \cdot src_{int8}(n, ic, ih, iw)$
- $weights_{f32}(oc, ic, kh, kw) = scale_{weights}(oc) \cdot weights_{int8}(oc, ic, kh, kw)$
- $dst_{f32}(n, oc, oh, ow) = scale_{dst} \cdot dst_{int8}(n, oc, oh, ow)$

Note that now the weights' scaling factor depends on oc .

To compute the dst_{int8} we need to perform the following:

$$dst_{int8}(n, oc, oh, ow) = f32_to_int8\left(\frac{scale_{src} \cdot scale_{weights}(oc)}{scale_{dst}} \cdot conv_{s32}(src_{int8}, weights_{int8})|_{(n, oc, oh, ow)}\right).$$

The user is responsible for preparing quantized weights accordingly. To do that, oneDNN provides reorders that can perform per-channel scaling:

$$weights_{int8}(oc, ic, kh, kw) = f32_to_int8(weights_{f32}(oc, ic, kh, kw) / scale_{weights}(oc)).$$

The *Quantization* describes what kind of quantization model oneDNN supports.

Support

oneDNN supports $int8$ computations for inference by allowing to specify that primitive input and output memory objects use $int8$ data types.

5.4.2 Memory

There are two levels of abstraction for memory in oneDNN.

1. *Memory descriptor* – engine-agnostic logical description of data (number of dimensions, dimension sizes, *data type*, and *format*).
2. *Memory object* – an engine-specific object combines memory descriptor with storage.

oneDNN defines the following convenience aliases to denote tensor dimensions

```
using dnnl::memory::dim = int64_t
Integer type for representing dimension sizes and indices.
```

```
using dnnl::memory::dims = std::vector<dim>
Vector of dimensions. Implementations are free to force a limit on the vector's length.
```

Memory Formats

In oneDNN memory format is how a multidimensional tensor is stored in 1-dimensional linear memory address space. oneDNN specifies two kinds of memory formats: *plain* which correspond to traditional multidimensional arrays, and *optimized* which are completely opaque.

Plain Memory Formats

Plain memory formats describe how multidimensional tensors are laid out in memory using an array of dimensions and an array of strides both of which have length equal to the rank of the tensor. In oneDNN the order of dimensions is fixed and different dimensions can have certain canonical interpretation depending on the primitive. For example, for CNN primitives the order for activation tensors is $\{N, C, \dots, D, H, W\}$, where N stands for minibatch (or batch size), C stands for channels, and D , H , and W stand for image spatial dimensions: depth, height and width respectively. Spatial dimensions may be omitted in the order from outermost to innermost; for example, it is not possible to omit H when D is present and it is never possible to omit W . Canonical interpretation is documented for each primitive. However, this means that the strides array plays an important role defining the order in which different dimension are laid out in memory. Moreover, the strides need to agree with dimensions.

More precisely, let T be a tensor of rank n and let σ be the permutation of the strides array that sorts it, i.e. $\text{strides}[\sigma(i)] \geq \text{strides}[\sigma(j)]$ if $\sigma(i) < \sigma(j)$ for all $0 \leq i, j < n$. Then the following must hold:

$$\text{strides}[\sigma(i)] \geq \text{strides}[\sigma(j)] * \text{dimensions}[\sigma(j)] \text{ if } \sigma(i) < \sigma(j) \text{ for all } 0 \leq i, j < n.$$

For an element with coordinates (i_0, \dots, i_{n-1}) such that $0 \leq i_j < \text{dimensions}[\sigma(j)]$ for $0 \leq j < n$, its offset in memory is computed as:

$$\text{offset}(i_0, \dots, i_{n-1}) = \text{offset}_0 + \sum_{j=0}^{n-1} i_j * \text{strides}[\sigma(j)].$$

Here offset_0 is the offset from the *parent* memory and is non-zero only for *submemory* memory descriptors created using `dnnl::memory::desc::submemory_desc()`. Submemory memory descriptors inherit strides from the parent memory descriptor. Their main purpose is to express in-place concat operations.

As an example, consider an $M \times N$ matrix A (M rows times N columns). Regardless of whether A is stored transposed or not, $\text{dimensions}_A = \{M, N\}$. However, $\text{strides}_A = \{LDA, 1\}$ if it is not transposed and $\text{strides}_A = \{1, LDA\}$ if it is, where LDA is such that $LDA \geq N$ if A is not transposed, and $LDA \geq M$ if it is. This also shows that A does not have to be stored *densly* in memory.

Note: The example above shows that oneDNN assumes data to be stored in row-major order.

Code example:

```
int M, N;
dnnl::memory::dims dims {M, N}; // Dimensions always stay the same

// Non-transposed matrix
dnnl::memory::dims strides_non_transposed {N, 1};
dnnl::memory::desc A_non_transposed {dims, dnnl::memory::data_type::f32,
    strides_non_transposed};

// Transposed matrix
dnnl::memory::dims strides_transposed {1, M};
dnnl::memory::desc A_transposed {dims, dnnl::memory::data_type::f32,
    strides_transposed};
```

Format Tags

In addition to strides, oneDNN provides named *format tags* via the `dnnl::memory::format_tag` enum type. The enumerators of this type can be used instead of strides for dense plain layouts.

The format tag names for N -dimensional memory formats use first N letters of the English alphabet which can be arbitrarily permuted. This permutation is used to compute strides for tensors with up to 6 dimensions. The resulting strides specify dense storage, in other words, using the nomenclature from the previous section, the following equality holds:

$$\text{strides}[i] = \text{strides}[j] * \text{dimensions}[j] \text{ if } \sigma(i) + 1 = \sigma(j) \text{ for all } 0 \leq i, j < n - 1.$$

In the matrix example, we could have used `dnnl::memory::format_tag::ab` for the non-transposed matrix above, and `dnnl::memory::format_tag::ba` for the transposed:

```
int M, N;
dnnl::memory::dims dims {M, N}; // Dimensions always stay the same

// Non-transposed matrix
dnnl::memory::desc A_non_transposed {dims, dnnl::memory::data_type::f32,
    dnnl::memory::format_tag::ab};

// Transposed matrix
dnnl::memory::desc A_transposed {dims, dnnl::memory::data_type::f32,
    dnnl::memory::format_tag::ba};
```

Note: In what follows in this section we abbreviate memory format tag names for readability. For example, `dnnl::memory::format_tag::abcd` is abbreviated to `abcd`.

In addition to abstract format tag names, oneDNN also provides convenience aliases. Some examples for CNNs and RNNs:

- `nchw` is an alias for `abcd` (see the canonical order order of dimensions for CNNs discussed above).
- `oihw` is an alias for `abcd`.
- `nhwc` is an alias for `acdb`.
- `tnc` is an alias for `abc`.
- `ldio` is an alias for `abcd`.
- `ldoi` is an alias for `abdc`.

Optimized Format ‘any’

Another kind of format that oneDNN supports is an opaque *optimized* memory format that cannot be created directly from strides and dimensions arrays. A memory descriptor for an optimized memory format can only be created by passing `any` when creating certain primitive descriptor. That primitive descriptor can then querying them for memory descriptors. Data in plain memory format should then be reordered into the data in optimized data format before computations. Since reorders are expensive, the optimized memory format needs to be propagated through computations graph.

Optimized formats can employ padding, blocking and other data transformations to keep data in layout optimal for a certain architecture. This means that it in general operations like `dnnl::memory::desc::permute_axes()` or

`dnnl::memory::desc::submemory_desc()` may fail. It is in general incorrect to use product of dimension sizes to calculate amount of memory required to store data: `dnnl::memory::desc::get_size()` must be used instead.

Memory Format Propagation

Memory format propagation is one of the central notions that needs to be well-understood to use oneDNN correctly.

Convolution, matmul, RNN and inner product primitives choose the memory format when you create them with the placeholder memory format `any` for input or output. The memory format chosen is based on different circumstances such as hardware and convolution parameters. Using the placeholder `any` memory format is the recommended practice for convolutions, since they are the most compute-intensive operations in most topologies where they are present.

Other primitives, such as Elementwise, LRN, batch normalization and other, on forward propagation should use the same memory format as the preceding layer thus propagating the memory format through multiple oneDNN primitives. This avoids unnecessary reorders which may be expensive and should be avoided unless a compute-intensive primitive requires a different format. For performance reasons, backward computations of such primitives requires consistent memory format with the corresponding forward computations. Hence, when initializing these primitives for backward computations you should use `dnnl::memory::format_tag::any` memory format tag as well.

Below is the short summary when to use and not to use memory format `any` during primitive descriptor construction:

Primitive Kinds	Forward Propagation	Backward Propagation	No Propagation
Compute intensive: (De-)convolution, Matmul, Inner product, RNN	Use <code>any</code>	Use <code>any</code>	N/A
Memory-bandwidth limited: Pooling, Layer and Batch Normalization, Local Response Normalization, Elementwise, Shuffle, Softmax	Use memory format from preceding layer for source tensors, and <code>any</code> for destination tensors	Use <code>any</code> for gradient tensors, and actual memory formats for data tensors	N/A
Memory-bandwidth limited: Reorder, Concat, Sum, Binary	N/A	N/A	Use memory format from preceding layer for source tensors, and <code>any</code> for destination tensors

Additional format synchronization is required between forward and backward propagation when running training workloads. This is achieved via the `hint_pd` arguments of primitive descriptor constructors for primitives that implement backward propagation.

API

```
enum class dnnl::memory::format_tag
    Memory format tag specification.
```

Memory format tags can be further divided into two categories:

- Domain-agnostic names, i.e. names that do not depend on the tensor usage in the specific primitive. These names use letters from a to f to denote logical dimensions and form the order in which the dimensions are laid in memory. For example, `dnnl::memory::format_tag::ab` is used to denote a 2D tensor where the second logical dimension (denoted as b) is the innermost, i.e. has stride = 1, and the first logical dimension (a) is laid out in memory with stride equal to the size of the second dimension. On the other

hand, `dnnl::memory::format_tag::ba` is the transposed version of the same tensor: the outermost dimension (a) becomes the innermost one.

- Domain-specific names, i.e. names that make sense only in the context of a certain domain, such as CNN. These names are aliases to the corresponding domain-agnostic tags and used mostly for convenience. For example, `dnnl::memory::format_tag::nc` is used to denote 2D CNN activations tensor memory format, where the channels dimension is the innermost one and the batch dimension is the outermost one. Moreover, `dnnl::memory::format_tag::nc` is an alias for `dnnl::memory::format_tag::ab`, because for CNN primitives the logical dimensions of activations tensors come in order: batch, channels, spatial. In other words, batch corresponds to the first logical dimension (a), and channels correspond to the second one (b).

The following domain-specific notation applies to memory format tags:

- 'n' denotes the mini-batch dimension
- 'c' denotes a channels dimension
- When there are multiple channel dimensions (for example, in convolution weights tensor), 'i' and 'o' denote dimensions of input and output channels
- 'g' denotes a groups dimension for convolution weights
- 'd', 'h', and 'w' denote spatial depth, height, and width respectively

Values:

enumerator **undef**

Undefined memory format tag.

enumerator **any**

Placeholder memory format tag. Used to instruct the primitive to select a format automatically.

enumerator **a**

plain 1D tensor

enumerator **ab**

plain 2D tensor

enumerator **ba**

permuted 2D tensor

enumerator **abc**

plain 3D tensor

enumerator **acb**

permuted 3D tensor

enumerator **bac**

permuted 3D tensor

enumerator **bca**

permuted 3D tensor

enumerator **cba**

permuted 3D tensor

enumerator **abcd**
plain 4D tensor

enumerator **abdc**
permuted 4D tensor

enumerator **acdb**
permuted 4D tensor

enumerator **bacd**
permuted 4D tensor

enumerator **bcda**
permuted 4D tensor

enumerator **cdba**
permuted 4D tensor

enumerator **dcab**
permuted 4D tensor

enumerator **abcde**
plain 5D tensor

enumerator **abdec**
permuted 5D tensor

enumerator **acbde**
permuted 5D tensor

enumerator **acdeb**
permuted 5D tensor

enumerator **bacde**
permuted 5D tensor

enumerator **bcdea**
permuted 5D tensor

enumerator **cdeba**
permuted 5D tensor

enumerator **decab**
permuted 5D tensor

enumerator **abcdef**
plain 6D tensor

enumerator **acbdef**
plain 6D tensor

- enumerator **defcab**
plain 6D tensor
- enumerator **x**
1D tensor; an alias for *dnnl::memory::format_tag::a*
- enumerator **nc**
2D CNN activations tensor; an alias for *dnnl::memory::format_tag::ab*
- enumerator **cn**
2D CNN activations tensor; an alias for *dnnl::memory::format_tag::ba*
- enumerator **tn**
2D RNN statistics tensor; an alias for *dnnl::memory::format_tag::ab*
- enumerator **nt**
2D RNN statistics tensor; an alias for *dnnl::memory::format_tag::ba*
- enumerator **ncw**
3D CNN activations tensor; an alias for *dnnl::memory::format_tag::abc*
- enumerator **nwc**
3D CNN activations tensor; an alias for *dnnl::memory::format_tag::acb*
- enumerator **nchw**
4D CNN activations tensor; an alias for *dnnl::memory::format_tag::abcd*
- enumerator **nhwc**
4D CNN activations tensor; an alias for *dnnl::memory::format_tag::acdb*
- enumerator **chwn**
4D CNN activations tensor; an alias for *dnnl::memory::format_tag::bcda*
- enumerator **ncdhw**
5D CNN activations tensor; an alias for *dnnl::memory::format_tag::abcde*
- enumerator **ndhwc**
5D CNN activations tensor; an alias for *dnnl::memory::format_tag::acdeb*
- enumerator **oi**
2D CNN weights tensor; an alias for *dnnl::memory::format_tag::ab*
- enumerator **io**
2D CNN weights tensor; an alias for *dnnl::memory::format_tag::ba*
- enumerator **oiw**
3D CNN weights tensor; an alias for *dnnl::memory::format_tag::abc*
- enumerator **owi**
3D CNN weights tensor; an alias for *dnnl::memory::format_tag::acb*

- enumerator **wio**
3D CNN weights tensor; an alias for *dnnl::memory::format_tag::cba*
- enumerator **iwo**
3D CNN weights tensor; an alias for *dnnl::memory::format_tag::bca*
- enumerator **oihw**
4D CNN weights tensor; an alias for *dnnl::memory::format_tag::abcd*
- enumerator **hwio**
4D CNN weights tensor; an alias for *dnnl::memory::format_tag::cdba*
- enumerator **ohwi**
4D CNN weights tensor; an alias for *dnnl::memory::format_tag::acdb*
- enumerator **ihwo**
4D CNN weights tensor; an alias for *dnnl::memory::format_tag::bcda*
- enumerator **iohw**
4D CNN weights tensor; an alias for *dnnl::memory::format_tag::bacd*
- enumerator **oidhw**
5D CNN weights tensor; an alias for *dnnl::memory::format_tag::abcde*
- enumerator **dhwio**
5D CNN weights tensor; an alias for *dnnl::memory::format_tag::cdeba*
- enumerator **odhwi**
5D CNN weights tensor; an alias for *dnnl::memory::format_tag::acdeb*
- enumerator **iodhw**
5D CNN weights tensor; an alias for *dnnl::memory::format_tag::bacde*
- enumerator **idhwo**
5D CNN weights tensor; an alias for *dnnl::memory::format_tag::bcdea*
- enumerator **goiw**
4D CNN weights tensor with groups; an alias for *dnnl::memory::format_tag::abcd*
- enumerator **wigo**
4D CNN weights tensor with groups; an alias for *dnnl::memory::format_tag::dcab*
- enumerator **goihw**
5D CNN weights tensor with groups; an alias for *dnnl::memory::format_tag::abcde*
- enumerator **hwigo**
5D CNN weights tensor with groups; an alias for *dnnl::memory::format_tag::decab*
- enumerator **giohw**
5D CNN weights tensor with groups; an alias for *dnnl::memory::format_tag::acbde*

enumerator **goidhw**

6D CNN weights tensor with groups; an alias for *dnnl::memory::format_tag::abcdef*

enumerator **giodhw**

6D CNN weights tensor with groups; an alias for *dnnl::memory::format_tag::abcdef*

enumerator **dhwigo**

6D CNN weights tensor with groups; an alias for *dnnl::memory::format_tag::defcab*

enumerator **tnc**

3D RNN data tensor in the format (seq_length, batch, input channels).

enumerator **ntc**

3D RNN data tensor in the format (batch, seq_length, input channels).

enumerator **ldnc**

4D RNN states tensor in the format (num_layers, num_directions, batch, state channels).

enumerator **ldigo**

5D RNN weights tensor in the format (num_layers, num_directions, input_channels, num_gates, output_channels).

- For LSTM cells, the gates order is input, forget, candidate and output gate.
- For GRU cells, the gates order is update, reset and output gate.

enumerator **ldgoi**

5D RNN weights tensor in the format (num_layers, num_directions, num_gates, output_channels, input_channels).

- For LSTM cells, the gates order is input, forget, candidate and output gate.
- For GRU cells, the gates order is update, reset and output gate.

enumerator **ldio**

4D LSTM projection tensor in the format (num_layers, num_directions, num_channels_in_hidden_state, num_channels_in_recurrent_projection).

enumerator **ldoi**

4D LSTM projection tensor in the format (num_layers, num_directions, num_channels_in_recurrent_projection, num_channels_in_hidden_state).

enumerator **ldgo**

4D RNN bias tensor in the format (num_layers, num_directions, num_gates, output_channels).

- For LSTM cells, the gates order is input, forget, candidate and output gate.
- For GRU cells, the gates order is update, reset and output gate.

Memory Descriptors and Objects

Descriptors

Memory descriptor is an engine-agnostic logical description of data (number of dimensions, dimension sizes, and data type), and, optionally, the information about the physical format of data in memory. If this information is not known yet, a memory descriptor can be created with format tag set to `dnnl::memory::format_tag::any`. This allows compute-intensive primitives to choose the most appropriate physical format for the computations. The user is then responsible for reordering their data into the proper format they do not match. See *Memory Format Propagation* for more details.

A memory descriptor can be initialized either by specifying dimensions, and memory format tag or strides for each of them.

User can query amount of memory required by a memory descriptor using the `dnnl::memory::desc::get_size()` function. The size of data in general cannot be computed as the product of dimensions multiplied by the size of the data type. So users are required to use this function for better code portability.

Two memory descriptors can be compared using the equality and inequality operators. The comparison is especially useful when checking whether it is necessary to reorder data from the user's data format to a primitive's format.

Along with ordinary memory descriptors with all dimensions being positive, oneDNN supports *zero-volume* memory descriptors with one or more dimensions set to zero. This is used to support the NumPy* convention. If a zero-volume memory is passed to a primitive, the primitive typically does not perform any computations with this memory. For example:

- The concatenation primitive would ignore all memory object with zeroes in the concatenation dimension / axis.
- A forward convolution with a source memory object with zero in the minibatch dimension would always produce a destination memory object with a zero in the minibatch dimension and perform no computations.
- However, a forward convolution with a zero in one of the weights dimensions is ill-defined and is considered to be an error by the library because there is no clear definition on what the output values should be.

Data handle of a zero-volume memory is never accessed.

Note: Some primitives support implicit broadcast semantic when a given tensor has a dimensions set to 1 (similar to NumPY broadcast semantic). In particular, if an operation expects two tensors with same dimensions, and one of the descriptors has some dimension set to 1, that dimension will be implicitly broadcasted to match the other tensor dimension.

API

```
struct dnnl::memory::desc
    A memory descriptor.
```

Public Functions

desc()

Constructs a zero (empty) memory descriptor. Such a memory descriptor can be used to indicate absence of an argument.

desc(const *dims* &adims, *data_type* adata_type, *format_tag* aformat_tag, bool allow_empty = false)

Constructs a memory descriptor.

Note: The logical order of dimensions corresponds to the `abc...` format tag, and the physical meaning of the dimensions depends both on the primitive that would operate on this memory and the operation context.

Parameters

- **adims** – Tensor dimensions.
- **adata_type** – Data precision/type.
- **aformat_tag** – Memory format tag.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case a zero memory descriptor will be constructed. This flag is optional and defaults to false.

desc(const *dims* &adims, *data_type* adata_type, const *dims* &strides, bool allow_empty = false)

Constructs a memory descriptor by strides.

Note: The logical order of dimensions corresponds to the `abc...` format tag, and the physical meaning of the dimensions depends both on the primitive that would operate on this memory and the operation context.

Parameters

- **adims** – Tensor dimensions.
- **adata_type** – Data precision/type.
- **strides** – Strides for each dimension.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case a zero memory descriptor will be constructed. This flag is optional and defaults to false.

desc **submemory_desc**(const *dims* &adims, const *dims* &offsets, bool allow_empty = false) const

Constructs a memory descriptor for a region inside an area described by this memory descriptor.

Parameters

- **adims** – Sizes of the region.
- **offsets** – Offsets to the region from the encompassing memory object in each dimension.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case a zero memory descriptor will be returned. This flag is optional and defaults to false.

Returns A memory descriptor for the region.

desc **reshape**(const *dims* &adims, bool allow_empty = false) const

Constructs a memory descriptor by reshaping an existing one. The new memory descriptor inherits the data type.

The operation ensures that the transformation of the physical memory format corresponds to the transformation of the logical dimensions. If such transformation is impossible, the function either throws an exception (default) or returns a zero memory descriptor depending on the `allow_empty` flag.

The reshape operation can be described as a combination of the following basic operations:

- i. Add a dimension of size 1. This is always possible.
- ii. Remove a dimension of size 1.
- iii. Split a dimension into multiple ones. This is possible only if the product of all tensor dimensions stays constant.
- iv. Join multiple consecutive dimensions into a single one. This requires that the dimensions are dense in memory and have the same order as their logical counterparts.
 - Here, ‘dense’ means: `stride for dim[i] == (stride for dim[i + 1]) * dim[i + 1]`;
 - And ‘same order’ means: `i < j` if and only if `stride for dim[j] <= stride for dim[i]`.

Note: Reshape may fail for optimized memory formats.

Parameters

- **adims** – New dimensions. The product of dimensions must remain constant.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case a zero memory descriptor will be returned. This flag is optional and defaults to false.

Returns A new memory descriptor with new dimensions.

desc **permute_axes**(const std::vector<int> &permutation, bool allow_empty = false) const

Constructs a memory descriptor by permuting axes in an existing one.

The physical memory layout representation is adjusted accordingly to maintain the consistency between the logical and physical parts of the memory descriptor. The new memory descriptor inherits the data type.

The logical axes will be permuted in the following manner:

```
for (i = 0; i < ndims(); i++)
    new_desc.dims()[permutation[i]] = dims()[i];
```

Example:

```
std::vector<int> permutation = {1, 0}; // swap the first and
                                   // the second axes
dnnl::memory::desc in_md(
    {2, 3}, data_type, memory::format_tag::ab);
dnnl::memory::desc expect_out_md(
    {3, 2}, data_type, memory::format_tag::ba);
assert(in_md.permute_axes(permutation) == expect_out_md);
```

Parameters

- **permutation** – Axes permutation.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case a zero memory descriptor will be returned. This flag is optional and defaults to false.

Returns A new memory descriptor with new dimensions.

memory::dims **dims**() const

Returns dimensions of the memory descriptor.

Potentially expensive due to the data copy involved.

Returns A copy of the dimensions vector.

memory::data_type **data_type**() const

Returns the data type of the memory descriptor.

Returns The data type.

size_t **get_size**() const

Returns size of the memory descriptor in bytes.

Returns The number of bytes required to allocate a memory buffer for the memory object described by this memory descriptor.

bool **is_zero**() const

Checks whether the memory descriptor is zero (empty).

Returns true if the memory descriptor describes an empty memory and false otherwise.

bool **operator==(const desc &other)** const

An equality operator.

Parameters **other** – Another memory descriptor.

Returns Whether this and the other memory descriptors have the same format tag, dimensions, strides, etc.

bool **operator!=(const desc &other)** const

An inequality operator.

Parameters **other** – Another memory descriptor.

Returns Whether this and the other memory descriptors describe different memory.

Objects

Memory objects combine memory descriptors with storage for data (a data handle). With USM, the data handle is simply a pointer to void. The data handle can be queried using `dnnl::memory::get_data_handle()` and set using `dnnl::memory::set_data_handle()`. The underlying SYCL buffer, when used, can be queried using `dnnl::sycl_interop::get_buffer()` and set using `dnnl::sycl_interop::set_buffer()`. In addition, the memory descriptor and the engine underlying a memory object can be queried using `dnnl::memory::get_desc()` and `dnnl::memory::get_engine()` respectively.

API

struct `dnnl::memory`
Memory object.

A memory object encapsulates a handle to a memory buffer allocated on a specific engine, tensor dimensions, data type, and memory format, which is the way tensor indices map to offsets in linear memory space. Memory objects are passed to primitives during execution.

Public Functions

`memory()`

Default constructor.

Constructs an empty memory object, which can be used to indicate absence of a parameter.

`memory(const desc &md, const engine &aengine, void *handle)`

Constructs a memory object.

Unless `handle` is equal to `DNNL_MEMORY_NONE`, the constructed memory object will have the underlying buffer set. In this case, the buffer will be initialized as if `dnnl::memory::set_data_handle()` has been called.

See also:

`memory::set_data_handle()`

Parameters

- `md` – Memory descriptor.
- `aengine` – Engine to store the data on.
- `handle` – Handle of the memory buffer to use.
 - A pointer to the user-allocated buffer. In this case the library doesn't own the buffer.
 - The `DNNL_MEMORY_ALLOCATE` special value. Instructs the library to allocate the buffer for the memory object. In this case the library owns the buffer and the memory allocation kind of the underlying buffer is `dnnl::sycl_interop::memory_kind::usm`.
 - `DNNL_MEMORY_NONE` to create `dnnl::memory` without an underlying buffer.

`memory(const desc &md, const engine &aengine)`

Constructs a memory object.

The underlying buffer for the memory will be allocated by the library. The memory allocation kind of the underlying buffer is `dnnl::sycl_interop::memory_kind::usm`.

Parameters

- `md` – Memory descriptor.
- `aengine` – Engine to store the data on.

`desc` `get_desc()` const

Returns the associated memory descriptor.

`engine` `get_engine()` const

Returns the associated engine.

void ***get_data_handle()** const
Returns the underlying memory buffer.

On the CPU engine, or when using USM, this is a pointer to the allocated memory.

void **set_data_handle**(void *handle, const *stream* &astream) const
Sets the underlying memory buffer.

This function may write zero values to the memory specified by the `handle` if the memory object has a zero padding area. This may be time consuming and happens each time this function is called. The operation is always blocking and the stream parameter is a hint.

Note: Even when the memory object is used to hold values that stay constant during the execution of the program (pre-packed weights during inference, for example), the function will still write zeroes to the padding area if it exists. Hence, the `handle` parameter cannot and does not have a `const` qualifier.

Parameters

- **handle** – Memory buffer to use. On the CPU engine or when USM is used, the memory buffer is a pointer to the actual data. It must have at least `dnnl::memory::desc::get_size()` bytes allocated.
- **astream** – Stream to use to execute padding in.

void **set_data_handle**(void *handle) const
Sets the underlying memory buffer.

See documentation for `dnnl::memory::set_data_handle(void *, const stream &) const` for more information.

Parameters handle – Memory buffer to use. For the CPU engine, the memory buffer is a pointer to the actual data. It must have at least `dnnl::memory::desc::get_size()` bytes allocated.

template<typename **T** = void>
T *map_data() const

Maps a memory object and returns a host-side pointer to a memory buffer with a copy of its contents.

Mapping enables read/write directly from/to the memory contents for engines that do not support direct memory access.

Mapping is an exclusive operation - a memory object cannot be used in other operations until it is unmapped via `dnnl::memory::unmap_data()` call.

Note: Any primitives working with the memory should be completed before the memory is mapped. Use `dnnl::stream::wait()` to synchronize the corresponding execution stream.

Note: The `map_data` and `unmap_data` functions are provided mainly for debug and testing purposes and their performance may be suboptimal.

Template Parameters T – Data type to return a pointer to.

Returns Pointer to the mapped memory.

void **unmap_data**(void *mapped_ptr) const
Unmaps a memory object and writes back any changes made to the previously mapped memory buffer.

Note: The `map_data` and `unmap_data` functions are provided mainly for debug and testing purposes and their performance may be suboptimal.

Parameters `mapped_ptr` – A pointer previously returned by `dnnl::memory::map_data()`.

enum class `dnnl::sycl_interop::memory_kind`

Memory allocation kinds.

Values:

enumerator **usm**

USM memory allocation kind.

enumerator **buffer**

Buffer memory allocation kind.

memory `dnnl::sycl_interop::make_memory`(const *memory::desc* &adesc, const *engine* &aengine, *memory_kind* akind, void *ahandle = DNNL_MEMORY_ALLOCATE)

Creates a memory object of a specified description and of a specified memory allocation kind, for a specified engine.

Note: If `akind` is `dnnl::sycl_interop::memory_kind::buffer`, and `ahandle` is not `DNNL_MEMORY_ALLOCATE` or `DNNL_MEMORY_NONE`, an exception is thrown.

Parameters

- **adesc** – Memory descriptor that describes the data.
- **aengine** – Engine to store the data on.
- **akind** – Memory allocation kind.
- **ahandle** – Handle of the memory data to use. This parameter is optional. By default, the underlying memory buffer is allocated internally, its memory allocation kind is `dnnl::sycl_interop::memory_kind::usm`, and the library owns the buffer. If `handle` is provided, the library does not own the buffer.

Returns Memory object described by `adesc` memory descriptor, which has `akind` memory allocation kind, and is attached to the `aengine` engine.

memory `dnnl::sycl_interop::make_memory`(const *memory::desc* &adesc, const *stream* &astream, *memory_kind* akind, void *ahandle = DNNL_MEMORY_ALLOCATE)

Creates a memory object of a specified description and of a specified memory allocation kind, for a specified stream.

Note: If `akind` is `dnnl::sycl_interop::memory_kind::buffer`, and `ahandle` is not `DNNL_MEMORY_ALLOCATE` or `DNNL_MEMORY_NONE`, an exception is thrown.

Parameters

- **adesc** – Memory descriptor that describes the data.
- **astream** – Stream object where the data is used.
- **akind** – Memory allocation kind.
- **ahandle** – Handle of the memory data to use. This parameter is optional. By default, the underlying memory buffer is allocated internally, its memory allocation kind is `dnnl::sycl_interop::memory_kind::usm`, and the library owns the buffer. If `handle` is provided, the library does not own the buffer.

Returns Memory object described by `adesc` memory descriptor, which has `akind` memory allocation kind, and used withing the `astream` stream.

```
template<typename T, int ndims>
memory dnnl::sycl_interop::make_memory(const memory::desc &adesc, const engine &aengine,
                                     cl::sycl::buffer<T, ndims> abuffer)
```

Creates a memory object using a specified SYCL buffer.

Note: When such memory object is created, it is implied that its memory allocation kind is `dnnl::sycl_interop::memory_kind::buffer`.

Template Parameters

- **T** – Data type of the specified SYCL buffer.
- **ndims** – Number of dimensions of the specified SYCL buffer.

Parameters

- **adesc** – Memory descriptor that describes the data within the specified buffer.
- **aengine** – Engine to store the data on.
- **abuffer** – SYCL buffer.

Returns Memory object which holds a `abuffer` SYCL buffer described by the `adesc` memory descriptor and attached to the `aengine` engine.

```
template<typename T, int ndims>
memory dnnl::sycl_interop::make_memory(const memory::desc &adesc, const stream &astream,
                                     cl::sycl::buffer<T, ndims> abuffer)
```

Creates a memory object using a specified SYCL buffer.

Note: When such memory object is created, it is implied that its memory allocation kind is `dnnl::sycl_interop::memory_kind::buffer`.

Template Parameters

- **T** – Data type of the specified SYCL buffer.
- **ndims** – Number of dimensions of the specified SYCL buffer.

Parameters

- **adesc** – Memory descriptor that describes the data within the specified buffer.
- **astream** – Stream object where the data is used.

- **abuffer** – SYCL buffer.

Returns Memory object which holds a **abuffer** SYCL buffer described by the **adesc** memory descriptor and used within the **astream** stream.

memory_kind `dnnl::sycl_interop::get_memory_kind(const memory &amemory)`

Returns the memory allocation kind of a specified memory object.

Note: The memory allocation kind of a memory object could be changed during its lifetime, by setting the USM handle or SYCL buffer of said memory object.

Parameters **amemory** – Memory object.

Returns Memory allocation kind of the **amemory** memory object.

template<typename **T**, int **ndims**>

void `dnnl::sycl_interop::set_buffer(memory &amemory, cl::sycl::buffer<T, ndims> abuffer)`

Sets the SYCL buffer underlying a specified memory object.

Note: By setting the SYCL buffer of a memory object its memory allocation kind will be changed to `dnnl::sycl_interop::memory_kind::buffer`.

Template Parameters

- **T** – Data type of the specified SYCL buffer.
- **ndims** – Number of dimensions of the specified SYCL buffer.

Parameters

- **amemory** – Memory object that will store the **abuffer** SYCL buffer.
- **abuffer** – SYCL buffer to be stored in the **amemory** memory object.

template<typename **T**, int **ndims**>

void `dnnl::sycl_interop::set_buffer(memory &amemory, cl::sycl::buffer<T, ndims> abuffer, stream &astream)`

Sets the SYCL buffer underlying a specified memory object in a specified stream.

Template Parameters

- **T** – Data type of the specified SYCL buffer.
- **ndims** – Number of dimensions of the specified SYCL buffer.

Parameters

- **amemory** – Memory object that will store the **abuffer** SYCL buffer.
- **abuffer** – SYCL buffer to be stored in the **amemory** memory object and used in the **astream** stream.
- **astream** – Stream object within which the **amemory** memory object is used.

template<typename **T**, int **ndims** = 1>

`cl::sycl::buffer<T, ndims> dnnl::sycl_interop::get_buffer(const memory &amemory)`

Returns the SYCL buffer underlying a specified memory object.

Template Parameters

- **T** – Data type of the specified SYCL buffer.
- **ndims** – Number of dimensions of the specified buffer.

Parameters **amemory** – Memory object.

Returns SYCL buffer of type T with ndims dimensions, underlying the amemory memory object.

DNNL_MEMORY_NONE

Special pointer value that indicates that a memory object should not have an underlying buffer.

DNNL_MEMORY_ALLOCATE

Special pointer value that indicates that the library needs to allocate an underlying buffer for a memory object.

5.5 Primitives

Primitives are functor objects that encapsulate a particular computation such as forward convolution, backward LSTM computations, or a data transformation operation. A single primitive can sometimes represent more complex fused computations such as a forward convolution followed by a ReLU.

The most important difference between a primitive and a pure function is that a primitive can store state.

One part of the primitive's state is immutable. For example, convolution primitives store parameters like tensor shapes and can pre-compute other dependent parameters like cache blocking. This approach allows oneDNN primitives to pre-generate code specifically tailored for the operation to be performed. The oneDNN programming model assumes that the time it takes to perform the pre-computations is amortized by reusing the same primitive to perform computations multiple times.

The mutable part of the primitive's state is referred to as a scratchpad. It is a memory buffer that a primitive may use for temporary storage only during computations. The scratchpad can either be owned by a primitive object (which makes that object non-thread safe) or be an execution-time parameter.

Conceptually, oneDNN establishes several layers of how to describe a computation from more abstract to more concrete:

- Primitives descriptors fully defines an operations's computation using the memory descriptors (`dnnl::memory::desc`) passed at construction, as well as the attributes. It also dispatches specific implementation based on the engine. Primitive descriptors can be used to query various primitive implementation details and, for example, to implement *memory format propagation* by inspecting expected memory formats via queries without having to fully instantiate a primitive. oneDNN may contain multiple implementations for the same primitive that can be used to perform the same particular computation. Primitive descriptors allow one-way iteration which allows inspecting multiple implementations. The library is expected to order the implementations from most to least preferred, so it should always be safe to use the one that is chosen by default.
- Primitives, which are the most concrete, and embody the actual executable code that will be run to perform the primitive computation.

On the API level:

- Primitives are represented as a class on the top level of the `dnnl` namespace that have `dnnl::primitive` as their base class, for example `dnnl::convolution_forward`
- Primitive descriptors are represented as classes named `primitive_desc` and nested within the corresponding primitive classes that have `dnnl::primitive_desc_base` as their base class (except for RNN primitives that derive from `dnnl::rnn_primitive_desc_base`), for example `dnnl::convolution_forward::primitive_desc`. The `dnnl::primitive_desc::next_impl()` member function provides a way to iterate over implementations.

```

namespace dnnl {
    struct something_forward : public primitive {
        struct desc {
            // Primitive-specific constructors.
        }
        struct primitive_desc : public primitive_desc_base {
            // Constructors and primitive-specific memory descriptor queries.
        }
    };
}

```

The sequence of actions to create a primitive is:

1. Create a primitive descriptor with the proper memory descriptors, engine and attributes. The primitive descriptor can contain memory descriptors with placeholder `dnnl::memory::format_tag::any` memory formats if the primitive supports it.
2. Create a primitive based on the primitive descriptor obtained in step 1.

5.5.1 Common Definitions

This section lists common types and definitions used by all or multiple primitives.

Base Class for Primitives

struct `dnnl::primitive`

Base class for all computational primitives.

Subclassed by `dnnl::augru_backward`, `dnnl::augru_forward`, `dnnl::batch_normalization_backward`, `dnnl::batch_normalization_forward`, `dnnl::binary`, `dnnl::concat`, `dnnl::convolution_backward_data`, `dnnl::convolution_backward_weights`, `dnnl::convolution_forward`, `dnnl::deconvolution_backward_data`, `dnnl::deconvolution_backward_weights`, `dnnl::deconvolution_forward`, `dnnl::eltwise_backward`, `dnnl::eltwise_forward`, `dnnl::gru_backward`, `dnnl::gru_forward`, `dnnl::inner_product_backward_data`, `dnnl::inner_product_backward_weights`, `dnnl::inner_product_forward`, `dnnl::layer_normalization_backward`, `dnnl::layer_normalization_forward`, `dnnl::lbr_augru_backward`, `dnnl::lbr_augru_forward`, `dnnl::lbr_gru_backward`, `dnnl::lbr_gru_forward`, `dnnl::lrn_backward`, `dnnl::lrn_forward`, `dnnl::lstm_backward`, `dnnl::lstm_forward`, `dnnl::matmul`, `dnnl::pooling_backward`, `dnnl::pooling_forward`, `dnnl::prelu_backward`, `dnnl::prelu_forward`, `dnnl::reduction`, `dnnl::reorder`, `dnnl::resampling_backward`, `dnnl::resampling_forward`, `dnnl::shuffle_backward`, `dnnl::shuffle_forward`, `dnnl::softmax_backward`, `dnnl::softmax_forward`, `dnnl::sum`, `dnnl::vanilla_rnn_backward`, `dnnl::vanilla_rnn_forward`

Public Types

enum class `kind`

Kinds of primitives supported by the library.

Values:

enumerator `undef`

Undefined primitive.

- enumerator **reorder**
A reorder primitive.
- enumerator **shuffle**
A shuffle primitive.
- enumerator **concat**
A (out-of-place) tensor concatenation primitive.
- enumerator **sum**
A summation primitive.
- enumerator **convolution**
A convolution primitive.
- enumerator **deconvolution**
A deconvolution primitive.
- enumerator **eltwise**
An element-wise primitive.
- enumerator **softmax**
A softmax primitive.
- enumerator **pooling**
A pooling primitive.
- enumerator **prelu**
A PReLU primitive.
- enumerator **lrn**
An LRN primitive.
- enumerator **batch_normalization**
A batch normalization primitive.
- enumerator **layer_normalization**
A layer normalization primitive.
- enumerator **inner_product**
An inner product primitive.
- enumerator **rnn**
An RNN primitive.
- enumerator **binary**
A binary primitive.
- enumerator **matmul**
A matmul (matrix multiplication) primitive.

enumerator **resampling**
A resampling primitive.

Public Functions

primitive()

Default constructor. Constructs an empty object.

primitive(const *primitive_desc_base* &pd)

Constructs a primitive from a primitive descriptor.

Parameters **pd** – Primitive descriptor.

inline *kind* **get_kind**() const

Returns the kind of the primitive.

Returns The primitive kind.

void **execute**(const *stream* &astream, const std::unordered_map<int, *memory*> &args) const

Executes computations specified by the primitive in a specified stream.

Arguments are passed via an arguments map containing <index, memory object> pairs. The index must be one of the `DNNL_ARG_*` values such as `DNNL_ARG_SRC`, and the memory must have a memory descriptor matching the one returned by `dnnl::primitive_desc_base::query_md(query::exec_arg_md, index)` unless using dynamic shapes (see `DNNL_RUNTIME_DIM_VAL`).

Parameters

- **astream** – Stream object. The stream must belong to the same engine as the primitive.
- **args** – Arguments map.

primitive &**operator**=(const *primitive* &rhs)

Assignment operator.

```
cl::sycl::event dnnl::sycl_interop::execute(const primitive &apimitive, const stream &astream, const
std::unordered_map<int, memory> &args, const
std::vector<cl::sycl::event> &dependencies = {})
```

Executes computations using a specified primitive object in a specified stream.

Arguments are passed via an arguments map containing <index, memory object> pairs. The index must be one of the `DNNL_ARG_*` values such as `DNNL_ARG_SRC`, and the memory must have a memory descriptor matching the one returned by `dnnl::primitive_desc_base::query_md(query::exec_arg_md, index)` unless using dynamic shapes (see `DNNL_RUNTIME_DIM_VAL`).

Parameters

- **apimitive** – Primitive to be executed.
- **astream** – Stream object. The stream must belong to the same engine as the primitive.
- **args** – Arguments map.
- **dependencies** – Vector of SYCL events that the execution depends on.

Returns SYCL event object for the specified primitive execution.

Base Class for Primitives Descriptors

There is a common base class for primitive descriptors.

```
struct dnnl::primitive_desc_base
```

Base class for all primitive descriptors.

Subclassed by `dnnl::concat::primitive_desc`, `dnnl::primitive_desc`, `dnnl::reorder::primitive_desc`, `dnnl::sum::primitive_desc`

Public Functions

```
primitive_desc_base()
```

Default constructor. Produces an empty object.

```
engine get_engine() const
```

Returns the engine of the primitive descriptor.

Returns The engine of the primitive descriptor.

```
const char *impl_info_str() const
```

Returns implementation name.

Returns The implementation name.

```
memory::dim query_s64(query what) const
```

Returns a `memory::dim` value (same as `int64_t`).

Parameters `what` – The value to query.

Returns The result of the query.

```
memory::dims get_strides() const
```

Returns strides.

Returns Strides.

Returns An empty `dnnl::memory::dims` if the primitive does not have a strides parameter.

```
memory::dims get_dilations() const
```

Returns dilations.

Returns Dilations.

Returns An empty `dnnl::memory::dims` if the primitive does not have a dilations parameter.

```
memory::dims get_padding_l() const
```

Returns a left padding.

Returns A left padding.

Returns An empty `dnnl::memory::dims` if the primitive does not have a left padding parameter.

```
memory::dims get_padding_r() const
```

Returns a right padding.

Returns A right padding.

Returns An empty `dnnl::memory::dims` if the primitive does not have a right padding parameter.

```
float get_epsilon() const
```

Returns an epsilon.

Returns An epsilon.

Returns Zero if the primitive does not have an epsilon parameter.

template<typename T = unsigned>

T **get_flags**() const

Returns flags.

Template Parameters T – Flags enumeration type.

Returns Flags.

Returns Zero if the primitive does not have a flags parameter.

dnnl::algorithm **get_algorithm**() const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

float **get_alpha**() const

Returns an alpha.

Returns An alpha.

Returns Zero if the primitive does not have an alpha parameter.

float **get_beta**() const

Returns a beta.

Returns A beta.

Returns Zero if the primitive does not have a beta parameter.

int **get_axis**() const

Returns an axis.

Returns An axis.

Returns A negative number if the primitive does not have an axis parameter.

memory::dim **get_local_size**() const

Returns an LRN local size parameter.

Returns An LRN local size parameter.

Returns Zero if the primitive does not have an LRN local size parameter.

float **get_k**() const

Returns an LRN K parameter.

Returns An LRN K parameter.

Returns Zero if the primitive does not have an LRN K parameter.

float **get_p**() const

Returns a reduction P parameter.

Returns A reduction P parameter.

Returns Zero if the primitive does not have a reduction P parameter.

std::vector<float> **get_factors**() const

Returns a resampling factors parameters.

Returns A vector of factors.

Returns An empty vector if the primitive does not have a resampling factors parameter.

`dnnl::algorithm` **get_cell_kind()** const

Returns an RNN cell kind parameter.

Returns An RNN cell kind parameter.

Returns `dnnl::algorithm::undef` if the primitive does not have an RNN cell kind parameter.

`dnnl::rnn_direction` **get_direction()** const

Returns an RNN direction parameter.

Returns An RNN direction parameter.

Returns `dnnl::rnn_direction::undef` if the primitive does not have an RNN direction parameter.

`dnnl::algorithm` **get_activation_kind()** const

Returns an RNN activation kind parameter.

Returns An RNN activation kind parameter.

Returns `dnnl::algorithm::undef` if the primitive does not have an RNN activation kind parameter.

`memory::dims` **get_kernel()** const

Returns a pooling kernel parameter.

Returns A pooling kernel parameter.

Returns An empty `dnnl::memory::dims` if the primitive does not have a pooling kernel parameter.

`memory::dim` **get_group_size()** const

Returns a shuffle group size parameter.

Returns A shuffle group size parameter.

Returns Zero if the primitive does not have a shuffle group size parameter.

`dnnl::prop_kind` **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns `dnnl::prop_kind::undef` if the primitive does not have a propagation parameter.

`memory::desc` **query_md**(query what, int idx = 0) const

Returns a memory descriptor.

Note: There are also convenience methods `dnnl::primitive_desc_base::src_desc()`, `dnnl::primitive_desc_base::dst_desc()`, and others.

Parameters

- **what** – The kind of parameter to query; can be `dnnl::query::src_md`, `dnnl::query::dst_md`, etc.
- **idx** – Index of the parameter. For example, convolution bias can be queried with `what = dnnl::query::weights_md` and `idx = 1`.

Returns The requested memory descriptor.

Returns A zero memory descriptor if the primitive does not have a parameter of the specified kind or index.

memory::desc **src_desc**(int idx) const

Returns a source memory descriptor.

Parameters **idx** – Source index.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter with index **pdx**.

memory::desc **dst_desc**(int idx) const

Returns a destination memory descriptor.

Parameters **idx** – Destination index.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter with index **pdx**.

memory::desc **bias_desc**() const

Returns the bias memory descriptor.

Returns The bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

memory::desc **weights_desc**(int idx) const

Returns a weights memory descriptor.

Parameters **idx** – Weights index.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter with index **pdx**.

memory::desc **diff_src_desc**(int idx) const

Returns a diff source memory descriptor.

Parameters **idx** – Diff source index.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source parameter with index **pdx**.

memory::desc **diff_dst_desc**(int idx) const

Returns a diff destination memory descriptor.

Parameters **idx** – Diff destination index.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter with index **pdx**.

memory::desc **diff_weights_desc**(int idx) const

Returns a diff weights memory descriptor.

Parameters **idx** – Diff weights index.

Returns Diff weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff weights parameter with index **pdx**.

memory::desc **src_desc()** const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc()** const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

memory::desc **weights_desc()** const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **diff_src_desc()** const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **diff_dst_desc()** const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

memory::desc **diff_weights_desc()** const

Returns a diff weights memory descriptor.

Returns Diff weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff weights parameter.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

memory::desc **scratchpad_desc()** const

Returns the scratchpad memory descriptor.

Returns scratchpad memory descriptor.

Returns A zero memory descriptor if the primitive does not require scratchpad parameter.

engine **scratchpad_engine()** const

Returns the engine on which the scratchpad memory is located.

Returns The engine on which the scratchpad memory is located.

primitive_attr **get_primitive_attr()** const

Returns the primitive attributes.

Returns The primitive attributes.

dnnl::primitive::kind **get_kind()** const

Returns the kind of the primitive descriptor.

Returns The kind of the primitive descriptor.

It is further derived from to provide base class for all primitives.

```
struct dnnl::primitive_desc : public dnnl::primitive_desc_base
```

A base class for descriptors of all primitives that have an operation descriptor and that support iteration over multiple implementations.

Subclassed by `dnnl::batch_normalization_backward::primitive_desc`, `dnnl::batch_normalization_forward::primitive_desc`, `dnnl::binary::primitive_desc`, `dnnl::convolution_backward_data::primitive_desc`, `dnnl::convolution_backward_weights::primitive_desc`, `dnnl::convolution_forward::primitive_desc`, `dnnl::deconvolution_backward_data::primitive_desc`, `dnnl::deconvolution_backward_weights::primitive_desc`, `dnnl::deconvolution_forward::primitive_desc`, `dnnl::eltwise_backward::primitive_desc`, `dnnl::eltwise_forward::primitive_desc`, `dnnl::inner_product_backward_data::primitive_desc`, `dnnl::inner_product_backward_weights::primitive_desc`, `dnnl::inner_product_forward::primitive_desc`, `dnnl::layer_normalization_backward::primitive_desc`, `dnnl::layer_normalization_forward::primitive_desc`, `dnnl::lrn_backward::primitive_desc`, `dnnl::lrn_forward::primitive_desc`, `dnnl::matmul::primitive_desc`, `dnnl::pooling_backward::primitive_desc`, `dnnl::pooling_forward::primitive_desc`, `dnnl::prelu_backward::primitive_desc`, `dnnl::prelu_forward::primitive_desc`, `dnnl::reduction::primitive_desc`, `dnnl::resampling_backward::primitive_desc`, `dnnl::resampling_forward::primitive_desc`, `dnnl::rnn_primitive_desc_base`, `dnnl::shuffle_backward::primitive_desc`, `dnnl::shuffle_forward::primitive_desc`, `dnnl::softmax_backward::primitive_desc`, `dnnl::softmax_forward::primitive_desc`

Public Functions

primitive_desc()

Default constructor. Produces an empty object.

bool **next_impl()**

Advances the primitive descriptor iterator to the next implementation.

Returns `true` on success, and `false` if the last implementation reached, in which case primitive descriptor is not modified.

The `dnnl::reorder`, `dnnl::sum` and `dnnl::concat` primitives also subclass `dnnl::primitive_desc` to implement their primitive descriptors.

RNN primitives further subclass the `dnnl::primitive_desc_base` to provide utility functions for frequently queried memory descriptors.

```
struct dnnl::rnn_primitive_desc_base : public dnnl::primitive_desc
```

Base class for primitive descriptors for RNN primitives.

Subclassed by `dnnl::augru_backward::primitive_desc`, `dnnl::augru_forward::primitive_desc`, `dnnl::gru_backward::primitive_desc`, `dnnl::gru_forward::primitive_desc`, `dnnl::lbr_augru_backward::primitive_desc`, `dnnl::lbr_augru_forward::primitive_desc`, `dnnl::lbr_gru_backward::primitive_desc`, `dnnl::lbr_gru_forward::primitive_desc`, `dnnl::lstm_backward::primitive_desc`, `dnnl::lstm_forward::primitive_desc`, `dnnl::vanilla_rnn_backward::primitive_desc`, `dnnl::vanilla_rnn_forward::primitive_desc`

Public Functions

`rnn_primitive_desc_base()`

Default constructor. Produces an empty object.

`memory::desc src_layer_desc()` const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

`memory::desc src_iter_desc()` const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

`memory::desc src_iter_c_desc()` const

Returns source recurrent cell state memory descriptor.

Returns Source recurrent cell state memory descriptor.

`memory::desc weights_layer_desc()` const

Returns weights layer memory descriptor.

Returns Weights layer memory descriptor.

`memory::desc weights_iter_desc()` const

Returns weights iteration memory descriptor.

Returns Weights iteration memory descriptor.

`memory::desc weights_peephole_desc()` const

Returns weights peephole memory descriptor.

Returns Weights peephole memory descriptor.

`memory::desc weights_projection_desc()` const

Returns weights projection memory descriptor.

Returns Weights projection memory descriptor.

`memory::desc augru_attention_desc()` const

Returns AUGRU attention memory descriptor.

Returns AUGRU attention memory descriptor.

`memory::desc bias_desc()` const

Returns bias memory descriptor.

Returns Bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

`memory::desc dst_layer_desc()` const

Returns destination layer memory descriptor.

Returns Destination layer memory descriptor.

`memory::desc dst_iter_desc()` const

Returns destination iteration memory descriptor.

Returns Destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

- memory::desc* **dst_iter_c_desc()** const
Returns destination recurrent cell state memory descriptor.
Returns Destination recurrent cell state memory descriptor.
- memory::desc* **diff_src_layer_desc()** const
Returns diff source layer memory descriptor.
Returns Diff source layer memory descriptor.
- memory::desc* **diff_src_iter_desc()** const
Returns diff source iteration memory descriptor.
Returns Diff source iteration memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff source iteration parameter.
- memory::desc* **diff_src_iter_c_desc()** const
Returns diff source recurrent cell state memory descriptor.
Returns Diff source recurrent cell state memory descriptor.
- memory::desc* **diff_weights_layer_desc()** const
Returns diff weights layer memory descriptor.
Returns Diff weights layer memory descriptor.
- memory::desc* **diff_weights_iter_desc()** const
Returns diff weights iteration memory descriptor.
Returns Diff weights iteration memory descriptor.
- memory::desc* **diff_weights_peephole_desc()** const
Returns diff weights peephole memory descriptor.
Returns Diff weights peephole memory descriptor.
- memory::desc* **diff_weights_projection_desc()** const
Returns diff weights projection memory descriptor.
Returns Diff weights projection memory descriptor.
- memory::desc* **diff_augru_attention_desc()** const
Returns diff AUGRU attention memory descriptor.
Returns Diff AUGRU attention memory descriptor.
- memory::desc* **diff_bias_desc()** const
Returns diff bias memory descriptor.
Returns Diff bias memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff bias parameter.
- memory::desc* **diff_dst_layer_desc()** const
Returns diff destination layer memory descriptor.
Returns Diff destination layer memory descriptor.
- memory::desc* **diff_dst_iter_desc()** const
Returns diff destination iteration memory descriptor.
Returns Diff destination iteration memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff destination iteration parameter.

memory::desc **diff_dst_iter_c_desc()** const

Returns diff destination recurrent cell state memory descriptor.

Returns Diff destination recurrent cell state memory descriptor.

Common Enumerations

enum class **dnnl::prop_kind**

Propagation kind.

Values:

enumerator **undef**

Undefined propagation kind.

enumerator **forward_training**

Forward data propagation (training mode). In this mode, primitives perform computations necessary for subsequent backward propagation.

enumerator **forward_inference**

Forward data propagation (inference mode). In this mode, primitives perform only computations that are necessary for inference and omit computations that are necessary only for backward propagation.

enumerator **forward_scoring**

Forward data propagation, alias for *dnnl::prop_kind::forward_inference*.

enumerator **forward**

Forward data propagation, alias for *dnnl::prop_kind::forward_training*.

enumerator **backward**

Backward propagation (with respect to all parameters).

enumerator **backward_data**

Backward data propagation.

enumerator **backward_weights**

Backward weights propagation.

enumerator **backward_bias**

Backward bias propagation.

enum class **dnnl::algorithm**

Kinds of algorithms.

Values:

enumerator **undef**

Undefined algorithm.

enumerator **convolution_auto**

Convolution algorithm that is chosen to be either direct or Winograd automatically

- enumerator **convolution_direct**
Direct convolution.
- enumerator **convolution_winograd**
Winograd convolution.
- enumerator **deconvolution_direct**
Direct deconvolution.
- enumerator **deconvolution_winograd**
Winograd deconvolution.
- enumerator **eltwise_abs**
Elementwise: abs.
- enumerator **eltwise_bounded_relu**
Elementwise: bounded_relu.
- enumerator **eltwise_clip**
Elementwise: clip.
- enumerator **eltwise_clip_use_dst_for_bwd**
Elementwise: clip (dst for backward)
- enumerator **eltwise_elu**
Elementwise: exponential linear unit (ELU)
- enumerator **eltwise_elu_use_dst_for_bwd**
Elementwise: exponential linear unit (ELU) (dst for backward)
- enumerator **eltwise_exp**
Elementwise: exponent.
- enumerator **eltwise_exp_use_dst_for_bwd**
Elementwise: exponent (dst for backward)
- enumerator **eltwise_gelu**
Elementwise: gelu alias for *dnnl::algorithm::eltwise_gelu_tanh*
- enumerator **eltwise_gelu_tanh**
Elementwise: tanh-based gelu.
- enumerator **eltwise_gelu_erf**
Elementwise: erf-based gelu.
- enumerator **eltwise_hardswish**
Elementwise: hardswish.
- enumerator **eltwise_hardsigmoid**
Elementwise: hardsigmoid.

enumerator **eltwise_linear**

Elementwise: linear.

enumerator **eltwise_log**

Elementwise: natural logarithm.

enumerator **eltwise_logistic**

Elementwise: logistic.

enumerator **eltwise_logistic_use_dst_for_bwd**

Elementwise: logistic (dst for backward)

enumerator **eltwise_mish**

Elementwise: mish.

enumerator **eltwise_pow**

Elementwise: pow.

enumerator **eltwise_relu**

Elementwise: rectified linear unit (ReLU)

enumerator **eltwise_relu_use_dst_for_bwd**

Elementwise: rectified linear unit (ReLU) (dst for backward)

enumerator **eltwise_round**

Elementwise: round.

enumerator **eltwise_soft_relu**

Elementwise: soft_relu.

enumerator **eltwise_sqrt**

Elementwise: square root.

enumerator **eltwise_sqrt_use_dst_for_bwd**

Elementwise: square root (dst for backward)

enumerator **eltwise_square**

Elementwise: square.

enumerator **eltwise_swish**

Elementwise: swish ($x \cdot \text{sigmoid}(a \cdot x)$)

enumerator **eltwise_tanh**

Elementwise: hyperbolic tangent non-linearity (tanh)

enumerator **eltwise_tanh_use_dst_for_bwd**

Elementwise: hyperbolic tangent non-linearity (tanh) (dst for backward)

enumerator **lrn_across_channels**

Local response normalization (LRN) across multiple channels.

enumerator **lrn_within_channel**
LRN within a single channel.

enumerator **pooling_max**
Max pooling.

enumerator **pooling_avg**
Average pooling exclude padding, alias for *dnnl::algorithm::pooling_avg_include_padding*

enumerator **pooling_avg_include_padding**
Average pooling include padding.

enumerator **pooling_avg_exclude_padding**
Average pooling exclude padding.

enumerator **vanilla_rnn**
RNN cell.

enumerator **vanilla_lstm**
LSTM cell.

enumerator **vanilla_gru**
GRU cell.

enumerator **lbr_gru**
GRU cell with linear before reset. Differs from original GRU in how the new memory gate is calculated:
 $c_t = \tanh(W_c * x_t + b_{c_x} + r_t * (U_c * h_{t-1} + b_{c_h}))$ LRB GRU expects 4 bias tensors on input: $[b_u, b_r, b_{c_x}, b_{c_h}]$

enumerator **binary_add**
Binary add.

enumerator **binary_mul**
Binary mul.

enumerator **binary_max**
Binary max.

enumerator **binary_min**
Binary min.

enumerator **binary_div**
Binary div.

enumerator **binary_sub**
Binary sub.

enumerator **binary_ge**
Binary greater than or equal.

enumerator **binary_gt**
Binary greater than.

- enumerator **binary_le**
Binary less than or equal.
- enumerator **binary_lt**
Binary less than.
- enumerator **binary_eq**
Binary equal.
- enumerator **binary_ne**
Binary not equal.
- enumerator **resampling_nearest**
Nearest Neighbor resampling method.
- enumerator **resampling_linear**
Linear (Bilinear, Trilinear) resampling method.
- enumerator **reduction_max**
Reduction using max operation.
- enumerator **reduction_min**
Reduction using min operation.
- enumerator **reduction_sum**
Reduction using sum operation.
- enumerator **reduction_mul**
Reduction using mul operation.
- enumerator **reduction_mean**
Reduction using mean operation.
- enumerator **reduction_norm_lp_max**
Reduction using norm_lp_max operation.
- enumerator **reduction_norm_lp_sum**
Reduction using norm_lp_sum operation.
- enumerator **reduction_norm_lp_power_p_max**
Reduction using norm_lp_power_p_max operation.
- enumerator **reduction_norm_lp_power_p_sum**
Reduction using norm_lp_power_p_sum operation.
- enumerator **softmax_accurate**
Softmax, numerically stable.
- enumerator **softmax_log**
LogSoftmax, numerically stable.

Normalization Primitives Flags

enum class `dnnl::normalization_flags` : unsigned
 Flags for normalization primitives (can be combined via '|')

Values:

enumerator **none**

Use no normalization flags. If specified, the library computes mean and variance on forward propagation for training and inference, outputs them on forward propagation for training, and computes the respective derivatives on backward propagation.

enumerator **use_global_stats**

Use global statistics. If specified, the library uses mean and variance provided by the user as an input on forward propagation and does not compute their derivatives on backward propagation. Otherwise, the library computes mean and variance on forward propagation for training and inference, outputs them on forward propagation for training, and computes the respective derivatives on backward propagation.

enumerator **use_scale**

Use scale and shift parameters. If specified, the user is expected to pass scale and shift as inputs on forward propagation. On backward propagation of type `dnnl::prop_kind::backward`, the library computes their derivatives. If not specified, the scale and shift parameters are not used by the library in any way.

enumerator **use_shift**

enumerator **fuse_norm_relu**

Fuse normalization with ReLU. On training, normalization will require the workspace to implement backward propagation. On inference, the workspace is not required and behavior is the same as when normalization is fused with ReLU using the post-ops API.

Execution argument indices

DNNL_ARG_SRC_0

Source argument #0.

DNNL_ARG_SRC

A special mnemonic for source argument for primitives that have a single source. An alias for `DNNL_ARG_SRC_0`.

DNNL_ARG_SRC_LAYER

A special mnemonic for RNN input vector. An alias for `DNNL_ARG_SRC_0`.

DNNL_ARG_FROM

A special mnemonic for reorder source argument. An alias for `DNNL_ARG_SRC_0`.

DNNL_ARG_SRC_1

Source argument #1.

DNNL_ARG_SRC_ITER

A special mnemonic for RNN input recurrent hidden state vector. An alias for `DNNL_ARG_SRC_1`.

DNNL_ARG_SRC_2

Source argument #2.

DNNL_ARG_SRC_ITER_C

A special mnemonic for RNN input recurrent cell state vector. An alias for *DNNL_ARG_SRC_2*.

DNNL_ARG_DST_0

Destination argument #0.

DNNL_ARG_DST

A special mnemonic for destination argument for primitives that have a single destination. An alias for *DNNL_ARG_DST_0*.

DNNL_ARG_TO

A special mnemonic for reorder destination argument. An alias for *DNNL_ARG_DST_0*.

DNNL_ARG_DST_LAYER

A special mnemonic for RNN output vector. An alias for *DNNL_ARG_DST_0*.

DNNL_ARG_DST_1

Destination argument #1.

DNNL_ARG_DST_ITER

A special mnemonic for RNN input recurrent hidden state vector. An alias for *DNNL_ARG_DST_1*.

DNNL_ARG_DST_2

Destination argument #2.

DNNL_ARG_DST_ITER_C

A special mnemonic for LSTM output recurrent cell state vector. An alias for *DNNL_ARG_DST_2*.

DNNL_ARG_WEIGHTS_0

Weights argument #0.

DNNL_ARG_WEIGHTS

A special mnemonic for primitives that have a single weights argument. Alias for *DNNL_ARG_WEIGHTS_0*.

DNNL_ARG_SCALE

Scale values argument of normalization primitives.

DNNL_ARG_SHIFT

Shift values argument of normalization primitives.

DNNL_ARG_WEIGHTS_LAYER

A special mnemonic for RNN weights applied to the layer input. An alias for *DNNL_ARG_WEIGHTS_0*.

DNNL_ARG_WEIGHTS_1

Weights argument #1.

DNNL_ARG_WEIGHTS_ITER

A special mnemonic for RNN weights applied to the recurrent input. An alias for *DNNL_ARG_WEIGHTS_1*.

DNNL_ARG_BIAS

Bias tensor argument.

DNNL_ARG_MEAN

Mean values tensor argument.

DNNL_ARG_VARIANCE

Variance values tensor argument.

DNNL_ARG_WORKSPACE

Workspace tensor argument. Workspace is used to pass information from forward propagation to backward propagation computations.

DNNL_ARG_SCRATCHPAD

Scratchpad (temporary storage) tensor argument.

DNNL_ARG_DIFF_SRC_0

Gradient (diff) of the source argument #0.

DNNL_ARG_DIFF_SRC

A special mnemonic for primitives that have a single diff source argument. An alias for [DNNL_ARG_DIFF_SRC_0](#).

DNNL_ARG_DIFF_SRC_LAYER

A special mnemonic for gradient (diff) of RNN input vector. An alias for [DNNL_ARG_DIFF_SRC_0](#).

DNNL_ARG_DIFF_SRC_1

Gradient (diff) of the source argument #1.

DNNL_ARG_DIFF_SRC_ITER

A special mnemonic for gradient (diff) of RNN input recurrent hidden state vector. An alias for [DNNL_ARG_DIFF_SRC_1](#).

DNNL_ARG_DIFF_SRC_2

Gradient (diff) of the source argument #2.

DNNL_ARG_DIFF_SRC_ITER_C

A special mnemonic for gradient (diff) of RNN input recurrent cell state vector. An alias for [DNNL_ARG_DIFF_SRC_1](#).

DNNL_ARG_DIFF_DST_0

Gradient (diff) of the destination argument #0.

DNNL_ARG_DIFF_DST

A special mnemonic for primitives that have a single diff destination argument. An alias for [DNNL_ARG_DIFF_DST_0](#).

DNNL_ARG_DIFF_DST_LAYER

A special mnemonic for gradient (diff) of RNN output vector. An alias for [DNNL_ARG_DIFF_DST_0](#).

DNNL_ARG_DIFF_DST_1

Gradient (diff) of the destination argument #1.

DNNL_ARG_DIFF_DST_ITER

A special mnemonic for gradient (diff) of RNN input recurrent hidden state vector. An alias for [DNNL_ARG_DIFF_DST_1](#).

DNNL_ARG_DIFF_DST_2

Gradient (diff) of the destination argument #2.

DNNL_ARG_DIFF_DST_ITER_C

A special mnemonic for gradient (diff) of RNN input recurrent cell state vector. An alias for [DNNL_ARG_DIFF_DST_2](#).

DNNL_ARG_DIFF_WEIGHTS_0

Gradient (diff) of the weights argument #0.

DNNL_ARG_DIFF_WEIGHTS

A special mnemonic for primitives that have a single diff weights argument. Alias for [DNNL_ARG_DIFF_WEIGHTS_0](#).

DNNL_ARG_DIFF_SCALE

Scale gradient argument of normalization primitives.

DNNL_ARG_DIFF_SHIFT

Shift gradient argument of normalization primitives.

DNNL_ARG_DIFF_WEIGHTS_LAYER

A special mnemonic for diff of RNN weights applied to the layer input. An alias for [DNNL_ARG_DIFF_WEIGHTS_0](#).

DNNL_ARG_DIFF_WEIGHTS_1

Gradient (diff) of the weights argument #1.

DNNL_ARG_DIFF_WEIGHTS_ITER

A special mnemonic for diff of RNN weights applied to the recurrent input. An alias for [DNNL_ARG_DIFF_WEIGHTS_1](#).

DNNL_ARG_DIFF_BIAS

Gradient (diff) of the bias tensor argument.

DNNL_ARG_MULTIPLE_SRC

Starting index for source arguments for primitives that take a variable number of source arguments.

DNNL_ARG_MULTIPLE_DST

Starting index for destination arguments for primitives that produce a variable number of destination arguments.

DNNL_ARG_ATTR_SCALES

Scaling factors provided at execution time.

DNNL_ARG_ATTR_ZERO_POINTS

Zero points provided at execution time.

DNNL_RUNTIME_DIM_VAL

A wildcard value for dimensions that are unknown at a primitive creation time.

DNNL_RUNTIME_SIZE_VAL

A `size_t` counterpart of the `DNNL_RUNTIME_DIM_VAL`. For instance, this value is returned by `dnnl::memory::desc::get_size()` if either of the dimensions or strides equal to `DNNL_RUNTIME_DIM_VAL`.

DNNL_RUNTIME_F32_VAL

A wildcard value for floating point values that are unknown at a primitive creation time.

DNNL_RUNTIME_S32_VAL

A wildcard value for `int32_t` values that are unknown at a primitive creation time.

5.5.2 Attributes

The parameters passed to create a primitive descriptor specify the basic problem description: the operation kind, the propagation kind, the input and output tensors descriptors (e.g. strides if applicable...), as well as the engine where the primitive will be executed.

Attributes specify some extra properties of the primitive. Users must create them before use and must set required specifics using the corresponding setters. The attributes are copied during primitive descriptor creation, so users can change or destroy attributes right after that.

If not modified, attributes can stay empty, which is equivalent to the default attributes. Primitive descriptors' constructors have empty attributes as default parameters, so, unless required, users can simply omit them.

Attributes can also contain *post-ops*, which are computations executed after the primitive.

Post-ops

Post-ops are operations that are appended after a primitive. They are implemented using the *Attributes* mechanism. If there are multiple post-ops, they are executed in the order they have been appended as follow:

$$\text{dst} = \text{po}[n](\text{po}[n - 1](\dots(\text{po}[0](\text{OP}()))))$$

Note: Post-ops does not preserve intermediate data during computation. This typically makes them suitable for inference only.

The post-ops are represented by `dnnl::post_ops` which is copied once it is attached to the attributes using `dnnl::primitive_attr::set_post_ops()` function. The attributes then need to be passed to a primitive descriptor creation function to take effect. Below is a simple sketch:

```
dnnl::post_ops po; // default empty post-ops
assert(po.len() == 0); // no post-ops attached

po.append_SOMETHING(params); // append some particular post-op
po.append_SOMETHING_ELSE(other_params); // append one more post-op
```

(continues on next page)

(continued from previous page)

```
// (!) Note that the order in which post-ops are appended matters!
assert(po.len() == 2);

dnnl::primitive_attr attr; // default attributes
attr.set_post_ops(po); // attach the post-ops to the attr
// any changes to po after this point don't affect the value stored in attr

primitive::primitive_desc op_pd(params, attr); // create a pd with the attr
```

Note: Different primitives may have different post-ops support. Moreover, the support might also depend on the actual implementation of a primitive. So robust code should be able to handle errors accordingly. See the *Attribute Related Error Handling*.

Note: Post-ops do not change memory format of the operation destination memory object.

The post-op objects can be inspected using the `dnnl::post_ops::kind()` function that takes an index of the post-op to inspect (that must be less than the value returned by `dnnl::post_ops::len()`), and returns its kind.

Supported Post-ops

Eltwise Post-op

The eltwise post-op is appended using `dnnl::post_ops::append_eltwise()` function. The `dnnl::post_ops::kind()` returns `dnnl::primitive::kind::eltwise` for such a post-op.

The eltwise post-op replaces:

$$\text{dst}[:] = \text{Op}(\dots)$$

with

$$\text{dst}[:] = \text{scale} \cdot \text{eltwise}(\text{Op}(\dots))$$

The intermediate result of the `Op(...)` is not preserved.

The *scale* factor is supported in *int8* inference only. For all other cases the scale must be *1.0* (default value). The scale parameter is set to 1.0 by default, and can be set using the `dnnl::primitive_attr::set_scales_mask()` attribute for the argument `DNNL_ARG_ATTR_MULTIPLE_POST_OP`.

Sum Post-op

The sum post-op accumulates the result of a primitive with the existing data and is appended using `dnnl::post_ops::append_sum()` function. The `dnnl::post_ops::kind()` returns `dnnl::primitive::kind::sum` for such a post-op.

Prior to accumulating the result, the existing value is multiplied by scale. The *scale* factor is supported in *int8* inference only and should be used only when the result and the existing data have different magnitudes. For all other cases the scale must be *1.0* (default value). The scale parameter is set to 1.0 by default, and can be set using the `dnnl::primitive_attr::set_scales_mask()` attribute for the argument `DNNL_ARG_ATTR_MULTIPLE_POST_OP`.

Additionally, the sum post-op can reinterpret the destination values as a different data type of the same size. This may be used to, for example, reinterpret 8-bit signed data as unsigned or vice versa (which requires that values fall within a common range to work).

The sum post-op replaces

$$\text{dst}[:] = \text{Op}(\dots)$$

with

$$\text{dst}[:] = \text{scale} \cdot \text{as_data_type}(\text{dst}[:]) + \text{Op}(\dots)$$

Binary post-ops

The binary post-op replaces: .. math:

```
\dst[:] = \operatornamename{Op}\{Op\}(\dots)
```

with

$$\text{dst}[:] = \text{binary}(\text{Op}(\dots), \text{scale}[:] \cdot \text{Source}_1[:])$$

The binary post-op supports the same algorithms and broadcast semantic as the *binary primitive*.

Furthermore, the binary post-op scale parameter is set to 1.0 by default, and can be set using the `dnnl::primitive_attr::set_scales_mask()` attribute for the argument `DNNL_ARG_ATTR_MULTIPLE_POST_OP | DNNL_ARG_SRC_1`. For example:

```
primitive_attr attr;
post_ops p_ops;
p_ops.append_binary(algorithm::binary_add, summand_md);

attr.set_post_ops(p_ops);
attr.set_scales_mask(DNNL_ARG_ATTR_MULTIPLE_POST_OP(0) | DNNL_ARG_SRC_1,
    /* mask */ 0);
```

Examples of Chained Post-ops

Post-ops can be chained together by appending one after another. Note that the order matters: the post-ops are executed in the order they have been appended.

Sum -> ReLU

This pattern is pretty common for the CNN topologies of the ResNet family.

```
dnnl::post_ops po;
po.append_sum();
po.append_eltwise(
    /* algorithm = */ dnnl::algorithm::eltwise_relu,
    /* neg slope = */ 0.f,
    /* unused for ReLU */ 0.f);
```

(continues on next page)

(continued from previous page)

```
dnnl::primitive_attr attr;
attr.set_post_ops(po);

convolution_forward::primitive_desc(conv_d, attr, engine);
```

This will lead to the following computations:

$$\text{dst}[:,] = \text{ReLU}(\text{dst}[:,] + \text{conv}(\text{src}[:,], \text{weights}[:,]))$$

API

struct **dnnl::post_ops**
Post-ops.

Post-ops are computations executed after the main primitive computations and are attached to the primitive via primitive attributes.

Public Functions

post_ops()

Constructs an empty sequence of post-ops.

int **len()** const

Returns the number of post-ops entries.

primitive::kind **kind**(int index) const

Returns the primitive kind of post-op at entry with a certain index.

Parameters **index** – Index of the post-op to return the kind for.

Returns Primitive kind of the post-op at the specified index.

void **append_sum**(*memory::data_type* data_type = *memory::data_type::undef*)

Appends an accumulation (sum) post-op. Prior to accumulating the result, the previous value would be multiplied by a scaling factor **scale** provided as execution argument.

The kind of this post-op is *dnnl::primitive::kind::sum*.

This feature may improve performance for cases like residual learning blocks, where the result of convolution is accumulated to the previously computed activations. The parameter **scale** may be used for the integer-based computations when the result and previous activations have different logical scaling factors.

In the simplest case when the accumulation is the only post-op, the computations would be $\text{dst}[:,] := \text{scale} * \text{dst}[:,] + \text{op}(\dots)$ instead of $\text{dst}[:,] := \text{op}(\dots)$.

If **data_type** is specified, the original dst tensor will be reinterpreted as a tensor with the provided data type. Because it is a reinterpretation, **data_type** and dst data type should have the same size. As a result, computations would be $\text{dst}[:,] \leftarrow \text{scale} * \text{as_data_type}(\text{dst}[:,]) + \text{op}(\dots)$ instead of $\text{dst}[:,] \leftarrow \text{op}(\dots)$.

Note: This post-op executes in-place and does not change the destination layout.

Parameters **data_type** – Data type.

void **get_params_sum**(int index, float &scale) const
Returns the parameters of an accumulation (sum) post-op.

Parameters

- **index** – Index of the sum post-op.
- **scale** – Scaling factor of the sum post-op.

void **get_params_sum**(int index, float &scale, *memory::data_type* &data_type) const
Returns the parameters of an accumulation (sum) post-op.

Parameters

- **index** – Index of the sum post-op.
- **scale** – Scaling factor of the sum post-op.
- **data_type** – Data type of the sum post-op.

void **append_eltwise**(*algorithm* aalgorithm, float alpha, float beta)
Appends an elementwise post-op.

The kind of this post-op is *dnnl::primitive::kind::eltwise*.

In the simplest case when the elementwise is the only post-op, the computations would be `dst[:] := scale * eltwise_op (op(...))` instead of `dst[:] <- op(...)`, where `eltwise_op` is configured with the given parameters.

Parameters

- **aalgorithm** – Elementwise algorithm.
- **alpha** – Alpha parameter for the elementwise algorithm.
- **beta** – Beta parameter for the elementwise algorithm.

void **get_params_eltwise**(int index, *algorithm* &aalgorithm, float &alpha, float &beta) const
Returns parameters of an elementwise post-up.

Parameters

- **index** – Index of the post-op.
- **aalgorithm** – Output elementwise algorithm kind.
- **alpha** – Output alpha parameter for the elementwise algorithm.
- **beta** – Output beta parameter for the elementwise algorithm.

void **append_binary**(*algorithm* aalgorithm, const *memory::desc* &src1_desc)
Appends a binary post-op.

The kind of this post operation is *dnnl::primitive::kind::binary*.

In the simplest case when the binary is the only post operation, the computations would be:

```
dst[:] <- binary_op (dst[:], another_input[:])
```

where `binary_op` is configured with the given parameters. `binary_op` supports broadcast semantics for a second operand.

Parameters

- **aalgorithm** – Binary algorithm for the post-op.
- **src1_desc** – Memory descriptor of a second operand.

void **get_params_binary**(int index, *algorithm* &aalgorithm, *memory::desc* &src1_desc) const
Returns the parameters of a binary post-op.

Parameters

- **index** – Index of the binary post-op.
- **aalgorithm** – Output binary algorithm kind.
- **src1_desc** – Output memory descriptor of a second operand.

Scratchpad Mode

Some primitives might require a temporary buffer while performing their computations. For instance, the operations that do not have enough independent work to utilize all cores on a system might use parallelization over the reduction dimension (the K dimension in the GEMM notation). In this case different threads compute partial results in private temporary buffers, and then the private results are added to produce the final result. Another example is using matrix multiplication (GEMM) to implement convolution. Before calling GEMM, the source activations need to be transformed using the `im2col` operation. The transformation result is written to a temporary buffer that is then used as an input for the GEMM.

In both of these examples, the temporary buffer is no longer required once the primitive computation is completed. oneDNN refers to such kind of a memory buffer as a *scratchpad*.

Both types of implementation might need extra space for the reduction in case there are too few independent tasks. The amount of memory required by the `im2col` transformation is proportional to the size of the source image multiplied by the weights spatial size. The size of a buffer for reduction is proportional to the tensor size to be reduced (e.g., `diff_weights` in the case of backward by weights) multiplied by the number of threads in the reduction groups (the upper bound is the total number of threads).

By contrast, some other primitives might require very little extra space. For instance, one of the implementation of the `dnnl::sum` primitive requires temporary space only to store the pointers to data for each and every input array (that is, the size of the scratchpad is $n * \text{sizeof}(\text{void} *)$, where n is the number of summands).

oneDNN supports two modes for handling scratchpads:

```
enum class dnnl::scratchpad_mode
    Scratchpad mode.
```

Values:

enumerator **library**

The library manages the scratchpad allocation. There may be multiple implementation-specific policies that can be configured via mechanisms that fall outside of the scope of this specification.

enumerator **user**

The user manages the scratchpad allocation by querying and providing the scratchpad memory to primitives. This mode is thread-safe as long as the scratchpad buffers are not used concurrently by two primitive executions.

The scratchpad mode is controlled though the `dnnl::primitive_attr::set_scratchpad_mode()` primitive attributes.

If the user provides scratchpad memory to a primitive, this memory must be created using the same engine that the primitive uses.

All primitives support both scratchpad modes.

Note: Primitives are not thread-safe by default. The only way to make the primitive execution fully thread-safe is to use the `dnnl::scratchpad_mode::user` mode and not pass the same scratchpad memory to two primitives that are executed concurrently.

Examples

Library Manages Scratchpad

As mentioned above, this is a default behavior. We only want to highlight how a user can query the amount of memory consumed by a primitive due to a scratchpad.

```
// Use default attr, hence the library allocates scratchpad
dnnl::primitive::primitive_desc op_pd(params, /* other arguments */);

// Print how much memory would be hold by a primitive due to scratchpad
std::cout << "primitive will use "
           << op_pd.query_s64(dnnl::query::memory_consumption_s64)
           << " bytes" << std::endl;

// In this case scratchpad is internal, hence user visible scratchpad memory
// descriptor should be empty:
auto zero_md = dnnl::memory::desc();
```

User Manages Scratchpad

```
// Create an empty (default) attributes
dnnl::primitive_attr attr;

// Default scratchpad mode is `library`:
assert(attr.get_scratchpad_mode() == dnnl::scratchpad_mode::library);

// Set scratchpad mode to `user`
attr.set_scratchpad_mode(dnnl::scratchpad_mode::user);

// Create a primitive descriptor with custom attributes
dnnl::primitive::primitive_desc op_pd(op_d, attr, engine);

// Query the scratchpad memory descriptor
dnnl::memory::desc scratchpad_md = op_pd.scratchpad_desc();

// Note, that a primitive doesn't consume memory in this configuration:
assert(op_pd.query_s64(dnnl::query::memory_consumption_s64) == 0);

// Create a primitive
dnnl::primitive prim(op_pd);

// ... more code ..
```

(continues on next page)

(continued from previous page)

```

// Create a scratchpad memory
// NOTE: if scratchpad is not required for a particular primitive the
//       scratchpad_md.get_size() will return 0. It is fine to have
//       scratchpad_ptr == nullptr in this case.
void *scratchpad_ptr = user_memory_manager::allocate(scratchpad_md.get_size());
// NOTE: engine here must match the engine of the primitive
dnnl::memory scratchpad(scratchpad_md, engine, scratchpad_ptr);

// Pass a scratchpad memory to a primitive
prim.execute(stream, { /* other arguments */,
                     {DNNL_ARG_SCRATCHPAD, scratchpad}});

```

Quantization

Primitives may support reduced precision computations which require quantization. This process is explained in more details in the [Quantization Model](#) section.

Quantization Attributes (scales and zero-points)

oneDNN provides `dnnl::primitive_attr::set_scales_mask()` and `dnnl::primitive_attr::set_zero_points_mask()` for setting the quantization parameter for a given argument of a primitive.

The primitives may not support passing quantization parameters if source (and weights) tensors are not of the int8 data type. In other words, convolution operating on the single precision floating point data type may not scale and/or shift its inputs and outputs.

Broadcast semantic for quantization parameters is handled through masks that are explicitly passed to the `dnnl::primitive_attr::set_scales_mask()` and `dnnl::primitive_attr::set_zero_points_mask()` methods. For example, if the primitive destination is a $D_0 \times \dots \times D_{n-1}$ tensor and we want to have a scale per d_i dimension (where $0 \leq d_i < n$), then $mask = \sum_{d_i} 2^{d_i}$ and the number of scales should be `scales.size() = \prod_{d_i} D_{d_i}`. The mask should be set in attributes during primitive creation, and the actual scales and zero-points are passed as argument to the primitive execution function.

The quantization parameters are applied in the single precision floating point data type (`dnnl::memory::data_type::f32`). Before it is stored, the result is converted to the destination data type with saturation if required. The rounding happens according to the current hardware setting.

When using *Post-ops*, the same `dnnl::primitive_attr::set_scales_mask()` and `dnnl::primitive_attr::set_zero_points_mask()` are used to pass quantization parameters to a given post-ops arguments.

Example 1: weights quantization with per-output-channel scaling

```

// weights dimensions
const int OC, IC, KH, KW;

// original f32 weights in plain format
dnnl::memory::desc wei_plain_f32_md(
    {OC, IC, KH, KW},           // dims
    dnnl::memory::data_type::f32, // the data originally in f32

```

(continues on next page)

(continued from previous page)

```

        dnnl::memory::format_tag::hwigo // the plain memory format
    );

    // the scaling factors for quantized weights
    // An unique scale for each output-channel.
    std::vector<float> wei_scales(OC) = { /* values */ };
    dnnl::memory();

    // int8 convolution primitive descriptor
    dnnl::convolution_forward::primitive_desc conv_pd(/* see the next example */);

    // query the convolution weights memory descriptor
    dnnl::memory::desc wei_conv_s8_md = conv_pd.weights_desc();

    // prepare the attributes for the reorder
    dnnl::primitive_attr attr;
    const int quantization_mask = 0
        | (1 << 0); // scale per OC dimension, which is the dim #0
    attr.set_scales_mask(DNNL_ARG_DST, quantization_mask);

    // create reorder that would perform:
    // wei_s8(oc, ic, kh, kw) <- wei_f32(oc, ic, kh, kw) / scale(oc)
    // including the data format conversion.
    auto wei_reorder_pd = dnnl::reorder::primitive_desc(
        wei_plain_f32_md, engine, // source
        wei_conv_s8_md, engine, // destination,
        attr);
    auto wei_reorder = dnnl::reorder(wei_reorder_pd);

```

Example 2: convolution with groups, with per-output-channel quantization

This example is complementary to the previous example (which should ideally be the first one). Let's say we want to create an int8 convolution with per-output channel scaling.

```

const float src_scale; // src_f32[:] = src_scale * src_s8[:]
const float dst_scale; // dst_f32[:] = dst_scale * dst_s8[:]

// the scaling factors for quantized weights (as declared above)
// An unique scale for each group and output-channel.
std::vector<float> wei_scales(OC) = {...};

// Src, weights, and dst memory descriptors for convolution,
// with memory format tag == any to allow a convolution implementation
// to chose the appropriate memory format

dnnl::memory::desc src_conv_s8_any_md(
    {BATCH, IC, IH, IW}, // dims
    dnnl::memory::data_type::s8, // the data originally in s8
    dnnl::memory::format_tag::any // let convolution to choose
);

```

(continues on next page)

(continued from previous page)

```

dnnl::memory::desc wei_conv_s8_any_md(
    {OC, IC, KH, KW},           // dims
    dnnl::memory::data_type::s8, // the data originally in s8
    dnnl::memory::format_tag::any // let convolution to choose
);

dnnl::memory::desc dst_conv_s8_any_md(...); // ditto

// prepare the attributes for the convolution
dnnl::primitive_attr attr;
const int data_mask = 0; // scale and zero-point per tensor for source and destination
const int wei_mask = 0
    | (1 << 1); // scale per OC dimension, which is the dim #0 on weights tensor:
                // (   OC, IC, KH, KW)
                //   0  1  2  3

attr.set_scales_mask(DNNL_ARG_SRC, data_mask);
attr.set_zero_points_mask(DNNL_ARG_SRC, data_mask);

attr.set_scales_mask(DNNL_ARG_WEIGHTS, wei_mask);

attr.set_scales_mask(DNNL_ARG_DST, data_mask);
attr.set_zero_points_mask(DNNL_ARG_DST, data_mask);

// create a convolution primitive descriptor
auto conv_pd = dnnl::convolution_forward::primitive_desc(
    dnnl::prop_kind::forward_inference,
    dnnl::algorithm::convolution_direct,
    src_conv_s8_any_md,           // what's important is that
    wei_conv_s8_any_md,         // we specified that we want
    dst_conv_s8_any_md,         // computations in s8
    strides, padding_l, padding_r,
    dnnl::padding_kind::zero
    attr); // the attributes describe the quantization flow

```

Implicit downconversions and floating-point math mode

oneDNN provides `dnnl::primitive_attr::set_fpmath_mode()` to allow implicit downconversions from fp32 to lower accuracy datatypes during primitive execution. For some applications, it allows to speedup computations without noticeable impact on accuracy.

The `dnnl::primitive_attr::set_fpmath_mode()` primitive attribute specifies which implicit down-conversions are allowed for that given primitive. Only down-conversions from f32 to narrower data-types (f16, bf16, or tf32) are currently allowed. Furthermore these down-conversions are allowed only during computation, and do not affect the storage datatype (which must remain f32).

The `dnnl::primitive_attr::set_fpmath_mode()` primitive attribute can take 3 types of values:

- the *strict* mode disables any down-conversion (default).
- the *any* mode allows all conversions from f32 to a smaller floating-point datatype (f16, bf16, or tf32).

- a specific datatype (f16, bf16, or tf32) which specifically allows down-conversion only from f32 to a datatype at least as accurate as the specified data-type (at least same number of exponent and mantissa bits).

The default value for this attribute shall be *strict*. However, it is allowed to expose global functions or environment variables to change this default value.

This attribute is ignored if a primitive computation data-type is integral.

Attribute Related Error Handling

Since the attributes are created separately from the corresponding primitive descriptor, consistency checks are delayed. Users can successfully set attributes in whatever configuration they want. However, when they try to create a primitive descriptor with the attributes they set, it might happen that there is no primitive implementation that supports such a configuration. In this case the library will throw the `dnnl::error` exception.

API

```
struct dnnl::primitive_attr
    Primitive attributes.
```

Public Functions

```
primitive_attr()
```

Constructs default (empty) primitive attributes.

```
scratchpad_mode get_scratchpad_mode() const
```

Returns the scratchpad mode.

```
void set_scratchpad_mode(scratchpad_mode mode)
```

Sets scratchpad mode.

Parameters `mode` – Specified scratchpad mode.

```
fpmath_mode get_fpmath_mode() const
```

Returns the fpmath mode.

```
void set_fpmath_mode(fpmath_mode mode)
```

Sets fpmath mode.

Parameters `mode` – Specified fpmath mode.

```
int get_scales_mask(int arg) const
```

Returns scaling factors correspondence mask for a given memory argument.

Parameters `arg` – Parameter argument index as passed to the `primitive::execute()` call.

```
void set_scales_mask(int arg, int mask)
```

Sets scaling factors correspondence mask for a given memory argument.

See also:

`dnnl::primitive_attr::set_scales_mask`

Note: The order of dimensions does not depend on how elements are laid out in memory. For example:

- for a 2D CNN activations tensor the order is always (n, c)

- for a 4D CNN activations tensor the order is always (n, c, h, w)
- for a 5D CNN weights tensor the order is always

Parameters

- **arg** – Parameter argument index as passed to the `primitive::execute()` call.
- **mask** – Scaling factors correspondence mask that defines the correspondence between the `arg` tensor dimensions and the `scales` vector. Setting the *i*-th bit indicates that a dedicated scaling factor is used for each index along that dimension. Set the mask to 0 to use a common scaling factor for the whole tensor. The `scales` must be passed at execution time as an argument with index `DNNL_ARG_ATTR_SCALES`.

void **set_zero_points_mask**(int arg, int mask)
Sets zero points for primitive operations for a given memory argument.

See also:

`dnnl::primitive_attr::set_output_scales`

Parameters

- **arg** – Parameter argument index as passed to the `primitive::execute()` call.
- **mask** – Zero point correspondence mask that defines the correspondence between the tensor dimensions and the `zero_points` vector. The set *i*-th bit indicates that a dedicated zero point is used for each index along that dimension. Set the mask to 0 to use a common zero point for the whole output tensor. The zero points must be passed at execution time as an argument with index `DNNL_ARG_ATTR_ZERO_POINTS`.

const `post_ops` **get_post_ops**() const
Returns post-ops previously set via `set_post_ops()`.

Returns Post-ops.

void **set_post_ops**(const `post_ops` ops)
Sets post-ops.

Note: There is no way to check whether the post-ops would be supported by the target primitive. Any error will be reported by the respective primitive descriptor constructor.

Parameters `ops` – Post-ops object to copy post-ops from.

void **set_rnn_data_qparams**(float scale, float shift)
Sets quantization scale and shift parameters for RNN data tensors.

For performance reasons, the low-precision configuration of the RNN primitives expect input activations to have the unsigned 8-bit integer data type. The scale and shift parameters are used to quantize floating-point data to unsigned integer and must be passed to the RNN primitive using attributes.

The quantization formula is `scale * (data + shift)`.

Example usage:

```

// RNN parameters
int l = 2, t = 2, mb = 32, sic = 32, slc = 32, dic = 32, dlc = 32;
// Activations quantization parameters
float scale = 2.0f, shift = 0.5f;

primitive_attr attr;

// Set scale and shift for int8 quantization of activation
attr.set_rnn_data_qparams(scale, shift);

// Create and configure rnn op_desc
vanilla_rnn_forward::desc rnn_d(/* arguments */);
vanilla_rnn_forward::primitive_desc rnn_d(rnn_d, attr, engine);

```

Note: Quantization scale and shift are common for `src_layer`, `src_iter`, `dst_iter`, and `dst_layer`.

Parameters

- **scale** – The value to scale the data by.
- **shift** – The value to shift the data by.

void **set_rnn_weights_qparams**(int mask, const std::vector<float> &scales)

Sets quantization scaling factors for RNN weights tensors. The low-precision configuration of the RNN primitives expect input weights to use the signed 8-bit integer data type. The scaling factors are used to quantize floating-point data to signed integer and must be passed to RNN primitives using attributes.

Note: The dimension order is always native and does not depend on the actual layout used. For example, five-dimensional weights always have (l, d, i, g, o) logical dimension ordering.

Note: Quantization scales are common for `weights_layer` and `weights_iteration`

Parameters

- **mask** – Scaling factors correspondence mask that defines the correspondence between the output tensor dimensions and the `scales` vector. The set *i*-th bit indicates that a dedicated scaling factor should be used each index along that dimension. Set the mask to 0 to use a common scaling factor for the whole output tensor.
- **scales** – Constant vector of output scaling factors. The following equality must hold: $scales.size() = \prod_{d \in mask} weights.dims[d]$. Violations can only be detected when the attributes are used to create a primitive descriptor.

5.5.3 Batch Normalization

The batch normalization primitive performs a forward or backward batch normalization operation on tensors with number of dimensions equal to 2 or more. Variable names follow the standard *Conventions*.

The batch normalization operation is defined by the following formulas. We show formulas only for 2D spatial data which are straightforward to generalize to cases of higher and lower dimensions.

The different flavors of the primitive are controlled by the `flags` parameter that is passed to the primitive descriptor initialization function like `dnnl::batch_normalization_forward::primitive_desc`. Multiple flags can be combined using the bitwise OR operator (`|`).

Forward

$$\text{dst}(n, c, h, w) = \gamma(c) \cdot \frac{\text{src}(n, c, h, w) - \mu(c)}{\sqrt{\sigma^2(c) + \varepsilon}} + \beta(c),$$

where

- $\gamma(c)$ and $\beta(c)$ are optional scale and shift for a channel (controlled using the `use_scale` and `use_shift` flags),
- $\mu(c)$ and $\sigma^2(c)$ are mean and variance for a channel (controlled using the `use_global_stats` flag), and
- ε is a constant to improve numerical stability.

Mean and variance are computed at runtime or provided by a user. When mean and variance are computed at runtime, the following formulas are used:

- $\mu(c) = \frac{1}{NHW} \sum_{nhw} \text{src}(n, c, h, w),$
- $\sigma^2(c) = \frac{1}{NHW} \sum_{nhw} (\text{src}(n, c, h, w) - \mu(c))^2.$

The $\gamma(c)$ and $\beta(c)$ tensors are considered learnable.

In the training mode, the primitive also optionally supports fusion with ReLU activation with zero negative slope applied to the result (see `fuse_norm_relu` flag).

Note: The batch normalization primitive computes population mean and variance and not the sample or unbiased versions that are typically used to compute running mean and variance. * Using the mean and variance computed by the batch normalization primitive, running mean and variance $\hat{\mu}_i$ and $\hat{\sigma}_i^2$ where i is iteration number, can be computed as:

$$\begin{aligned}\hat{\mu}_{i+1} &= \alpha \cdot \hat{\mu}_i + (1 - \alpha) \cdot \mu, \\ \hat{\sigma}_{i+1}^2 &= \alpha \cdot \hat{\sigma}_i^2 + (1 - \alpha) \cdot \sigma^2.\end{aligned}$$

Difference Between Forward Training and Forward Inference

- If mean and variance are computed at runtime (i.e., `use_global_stats` is not set), they become outputs for the propagation kind `forward_training` (because they would be required during the backward propagation) and are not exposed for the propagation kind `forward_inference`.
- If batch normalization is created with ReLU fusion (i.e., `fuse_norm_relu` is set), for the propagation kind `forward_training` the primitive would produce a workspace memory as one extra output. This memory is required to compute the backward propagation. When the primitive is executed with propagation kind `forward_inference`, the workspace is not produced. Behavior would be the same as creating a batch normalization primitive with ReLU as a post-op (see section below).

Backward

The backward propagation computes $\text{diff_src}(n, c, h, w)$, $\text{diff_}\gamma(c)^*$, and $\text{diff_}\beta(c)^*$ based on $\text{diff_dst}(n, c, h, w)$, $\text{src}(n, c, h, w)$, $\mu(c)$, $\sigma^2(c)$, $\gamma(c)^*$, and $\beta(c)^*$.

The tensors marked with an asterisk are used only when the primitive is configured to use $\gamma(c)$ and $\beta(c)$ (i.e., `use_scale` and `use_shift` are set).

Execution Arguments

Depending on the flags and propagation kind, the batch normalization primitive requires different inputs and outputs. For clarity, a summary is shown below.

	<code>forward_infer</code>	<code>forward_training</code>	<code>backward</code>	<code>backward_data</code>
<code>none</code>	<i>In:</i> src; <i>Out:</i> dst	<i>In:</i> src; <i>Out:</i> dst, μ , σ^2	<i>In:</i> diff_dst, src, μ , σ^2 ; <i>Out:</i> diff_src	Same as for <code>backward</code>
<code>use_global_stats</code>	<i>In:</i> src, μ , σ^2 ; <i>Out:</i> dst	<i>In:</i> src, μ , σ^2 ; <i>Out:</i> dst	<i>In:</i> diff_dst, src, μ , σ^2 ; <i>Out:</i> diff_src	Same as for <code>backward</code>
<code>use_scale</code>	<i>In:</i> src, γ ; <i>Out:</i> dst	<i>In:</i> src, γ ; <i>Out:</i> dst, μ , σ^2	<i>In:</i> diff_dst, src, μ , σ^2 , γ ; <i>Out:</i> diff_src, diff_ γ	Not supported
<code>use_shift</code>	<i>In:</i> src, β ; <i>Out:</i> dst	<i>In:</i> src, β ; <i>Out:</i> dst, μ , σ^2	<i>In:</i> diff_dst, src, μ , σ^2 , β ; <i>Out:</i> diff_src, diff_ β	Not supported
<code>use_scale</code> <code>use_shift</code>	<i>In:</i> src, γ , β ; <i>Out:</i> dst	<i>In:</i> src, γ , β ; <i>Out:</i> dst, μ , σ^2	<i>In:</i> diff_dst, src, μ , σ^2 , γ , β ; <i>Out:</i> diff_src, diff_ γ , diff_ β	Not supported
<code>use_global_stats</code> <code>use_scale</code> <code>use_shift</code>	<i>In:</i> src, μ , σ^2 , γ , β ; <i>Out:</i> dst	<i>In:</i> src, μ , σ^2 , γ , β ; <i>Out:</i> dst	<i>In:</i> diff_dst, src, μ , σ^2 , γ , β ; <i>Out:</i> diff_src, diff_ γ , diff_ β	Not supported
<code>flags</code> <code>fuse_norm_relu</code>	<i>In:</i> same as with flags; <i>Out:</i> same as with flags	<i>In:</i> same as with flags; <i>Out:</i> same as with flags, workspace	<i>In:</i> same as with flags, workspace; <i>Out:</i> same as with flags	Same as for <code>backward</code> if flags do not contain <code>use_scale</code> or <code>use_shift</code> ; not supported otherwise

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<code>DNNL_ARG_SRC</code>
γ	<code>DNNL_ARG_SCALE</code>
β	<code>DNNL_ARG_SHIFT</code>
mean (μ)	<code>DNNL_ARG_MEAN</code>
variance (σ)	<code>DNNL_ARG_VARIANCE</code>
dst	<code>DNNL_ARG_DST</code>
workspace	<code>DNNL_ARG_WORKSPACE</code>
diff_dst	<code>DNNL_ARG_DIFF_DST</code>
diff_src	<code>DNNL_ARG_DIFF_SRC</code>
diff_ γ	<code>DNNL_ARG_DIFF_SCALE</code>
diff_ β	<code>DNNL_ARG_DIFF_SHIFT</code>

Operation Details

1. For forward propagation, the mean and variance might be either computed at runtime (in which case they are outputs of the primitive) or provided by a user (in which case they are inputs). In the latter case, a user must set the `use_global_stats` flag. For the backward propagation, the mean and variance are always input parameters.
2. The memory format and data type for `src` and `dst` are assumed to be the same, and in the API they are typically referred to as `data` (e.g., see `data_desc` in `dnnl::batch_normalization_forward::primitive_desc`). The same is true for `diff_src` and `diff_dst`. The corresponding memory descriptors are referred to as `diff_data_desc`.
3. Both forward and backward propagation support in-place operations, meaning that `src` can be used as input and output for forward propagation, and `diff_dst` can be used as input and output for backward propagation. In case of an in-place operation, the original data will be overwritten. Note, however, that backward propagation requires original `src`, hence the corresponding forward propagation should not be performed in-place.
4. As mentioned above, the batch normalization primitive can be fused with ReLU activation even in the training mode. In this case, on the forward propagation the primitive has one additional output, `workspace`, that should be passed during the backward propagation.

Data Types Support

The operation supports the following combinations of data types.

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Propagation	Source / Destination	Mean / Variance / Scale / Shift
forward / backward	<code>f32</code> , <code>bf16</code>	<code>f32</code>
forward	<code>f16</code>	<code>f32</code>
forward	<code>s8</code>	<code>f32</code>

Data Representation

Source, Destination, and Their Gradients

Like other CNN primitives, the batch normalization primitive expects data to be $N \times C \times SP_n \times \dots \times SP_0$ tensor.

The batch normalization primitive is optimized for the following memory formats:

Spatial	Logical tensor	Implementations optimized for memory formats
0D	NC	<code>nc (ab)</code>
1D	NCW	<code>ncw (abc)</code> , <code>nwc (acb)</code> , <i>optimized</i>
2D	NCHW	<code>nchw (abcd)</code> , <code>nhwc (acdb)</code> , <i>optimized</i>
3D	NCDHW	<code>ncdhw (abcde)</code> , <code>ndhwc (acdeb)</code> , <i>optimized</i>

Here *optimized* means the format chosen by the preceding compute-intensive primitive.

Statistics Tensors

The mean (μ) and variance (σ^2) are separate 1D tensors of size C .

The format of the corresponding memory object must be x (a).

If used, the scale (γ) and shift (β) are combined in a single 2D tensor of shape $2 \times C$.

The format of the corresponding memory object must be nc (ab).

Post-ops and Attributes

Propagation	Type	Operation	Description
forward	post-op	eltwise	Applies an eltwise operation to the output.

Note: Using ReLU as a post-op does not produce additional output in the workspace that is required to compute backward propagation correctly. Hence, one should use the *fuse_norm_relu* flag for training.

API

```
struct dnnl::batch_normalization_forward : public dnnl::primitive
    Batch normalization forward propagation primitive.
```

Public Functions

```
batch_normalization_forward()
    Default constructor. Produces an empty object.
```

```
batch_normalization_forward(const primitive_desc &pd)
    Constructs a batch normalization forward propagation primitive.
```

Parameters **pd** – Primitive descriptor for a batch normalization forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
    Primitive descriptor for a batch normalization forward propagation primitive.
```

Public Functions

```
primitive_desc() = default
    Default constructor. Produces an empty object.
```

```
primitive_desc(const engine &aengine, prop_kind aprop_kind, const memory::desc &src_desc, const
    memory::desc &dst_desc, float epsilon, normalization_flags flags, const
    primitive_attr &attr = default_attr(), bool allow_empty = false)
    Constructs a primitive descriptor for a batch normalization forward propagation primitive.
```

Note: In-place operation is supported: the dst can refer to the same memory as the src.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training` and `dnnl::prop_kind::forward_inference`.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **epsilon** – Batch normalization epsilon parameter.
- **flags** – Batch normalization flags (`dnnl::normalization_flags`).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc src_desc()` const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

`memory::desc dst_desc()` const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

`memory::desc weights_desc()` const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

`memory::desc workspace_desc()` const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

`memory::desc mean_desc()` const

Returns memory descriptor for mean.

Returns Memory descriptor for mean.

`memory::desc variance_desc()` const

Returns memory descriptor for variance.

Returns Memory descriptor for variance.

`dnnl::prop_kind get_prop_kind()` const

Returns a propagation kind.

Returns A propagation kind.

Returns `dnnl::prop_kind::undef` if the primitive does not have a propagation parameter.

`float get_epsilon()` const

Returns an epsilon.

Returns An epsilon.

Returns Zero if the primitive does not have an epsilon parameter.

`normalization_flags get_flags()` const

Returns normalization flags.

Returns Normalization flags.

`struct dnnl::batch_normalization_backward` : public `dnnl::primitive`

Batch normalization backward propagation primitive.

Public Functions

batch_normalization_backward()

Default constructor. Produces an empty object.

batch_normalization_backward(const *primitive_desc* &pd)

Constructs a batch normalization backward propagation primitive.

Parameters **pd** – Primitive descriptor for a batch normalization backward propagation primitive.

struct **primitive_desc** : public dnnl::*primitive_desc*

Primitive descriptor for a batch normalization backward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_dst_desc, const *memory::desc* &src_desc, float epsilon, *normalization_flags* flags, const *batch_normalization_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a batch normalization backward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::backward_data* and *dnnl::prop_kind::backward* (diffs for all parameters are computed in this case).
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **src_desc** – Source memory descriptor.
- **epsilon** – Batch normalization epsilon parameter.
- **flags** – Batch normalization flags (*dnnl::normalization_flags*).
- **hint_fwd_pd** – Primitive descriptor for a batch normalization forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **weights_desc**() const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

memory::desc **diff_src_desc**() const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **diff_dst_desc()** const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

memory::desc **diff_weights_desc()**

Returns a diff weights memory descriptor.

Returns Diff weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff weights parameter.

memory::desc **mean_desc()** const

Returns memory descriptor for mean.

Returns Memory descriptor for mean.

memory::desc **variance_desc()** const

Returns memory descriptor for variance.

Returns Memory descriptor for variance.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

dnnl::prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

float **get_epsilon()** const

Returns an epsilon.

Returns An epsilon.

Returns Zero if the primitive does not have an epsilon parameter.

normalization_flags **get_flags()** const

Returns normalization flags.

Returns Normalization flags.

5.5.4 Binary

The binary primitive computes a result of a binary elementwise operation between tensors source 0 and source 1.

$$\text{dst}(\bar{x}) = \text{src}_0(\bar{x}) \text{ op } \text{src}_1(\bar{x}),$$

where $\bar{x} = (x_0, \dots, x_n)$ and *op* is an operator like addition, multiplication, maximum or minimum. Variable names follow the standard *Conventions*.

Forward and Backward

The binary primitive does not have a notion of forward or backward propagations.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src ₀	<i>DNNL_ARG_SRC_0</i>
src ₁	<i>DNNL_ARG_SRC_1</i>
dst	<i>DNNL_ARG_DST</i>

Operation Details

- The binary primitive requires all source and destination tensors to have the same number of dimensions.
- The binary primitive supports implicit broadcast semantics for source 1. It means that if some dimension has value of one, this value will be used to compute an operation with each point of source 0 for this dimension.
- The dst memory format can be either specified explicitly or by *dnnl::memory::format_tag::any* (recommended), in which case the primitive will derive the most appropriate memory format based on the format of the source 0 tensor.
- Destination memory descriptor should completely match source 0 memory descriptor.
- The binary primitive supports in-place operations, meaning that source 0 tensor may be used as the destination, in which case its data will be overwritten.

Post-ops and Attributes

The following attributes should be supported:

Type	Operation	Description	Restrictions
Attribute	<i>Scales</i>	Sets scale(s) for the corresponding tensor(s)	
post-op	<i>Eltwise</i>	Applies an elementwise operation to the result	
post-op	<i>Binary</i>	Applies a binary operation to the result	
post-op	<i>Sum</i>	Adds the operation result to the destination tensor instead of overwriting it	

Data Types Support

The source and destination tensors may have `dnnl::memory::data_type::f32`, `dnnl::memory::data_type::bf16`, `dnnl::memory::data_type::s8` or `dnnl::memory::data_type::u8` data types.

Data Representation

The binary primitive works with arbitrary data tensors. There is no special meaning associated with any of tensors dimensions.

API

```
struct dnnl::binary : public dnnl::primitive
    Elementwise binary operator primitive.
```

Public Functions

`binary()`

Default constructor. Produces an empty object.

`binary(const primitive_desc &pd)`

Constructs an elementwise binary operation primitive.

Parameters `pd` – Primitive descriptor for an elementwise binary operation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
    Primitive descriptor for an elementwise binary operator primitive.
```

Public Functions

`primitive_desc() = default`

Default constructor. Produces an empty object.

```
primitive_desc(const engine &aengine, algorithm aalgorithm, const memory::desc &src0, const
memory::desc &src1, const memory::desc &dst, const primitive_attr &attr =
default_attr(), bool allow_empty = false)
```

Constructs a primitive descriptor for an elementwise binary operator primitive.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Elementwise binary algorithm.
- **src0** – Memory descriptor for source tensor #0.
- **src1** – Memory descriptor for source tensor #1.
- **dst** – Memory descriptor for destination tensor.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

```
memory::desc src_desc(int idx = 0) const
```

Returns a source memory descriptor.

Parameters `idx` – Source index.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter with index `pdx`.

memory::desc `src0_desc()` const

Returns the memory descriptor for source #0.

memory::desc `src1_desc()` const

Returns the memory descriptor for source #1.

memory::desc `dst_desc()` const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

algorithm `get_algorithm()` const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

5.5.5 Concat

A primitive to concatenate data by arbitrary dimension.

The concat primitive concatenates N tensors over `concat_dimension` (here denoted as C), and is defined as

$$\text{dst}(\overline{ou}, c, \overline{in}) = \text{src}_i(\overline{ou}, c', \overline{in}),$$

where

- $c = C_1 + \dots + C_{i-1} + c'$,
- \overline{ou} is the outermost indices (to the left from concat axis),
- \overline{in} is the innermost indices (to the right from concat axis), and

Variable names follow the standard *Conventions*.

Forward and Backward

The concat primitive does not have a notion of forward or backward propagations. The backward propagation for the concatenation operation is simply an identity operation.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_MULTIPLE_SRC</i>
dst	<i>DNNL_ARG_DST</i>

Operation Details

1. The dst memory format can be either specified by a user or derived by the primitive. The recommended way is to allow the primitive to choose the most appropriate format.
2. The concat primitive requires all source and destination tensors to have the same shape except for the `concat_dimension`. The destination dimension for the `concat_dimension` must be equal to the sum of the `concat_dimension` dimensions of the sources (i.e. $C = \sum_i C_i$). Implicit broadcasting is not supported.

Data Types Support

The concat primitive supports arbitrary data types for source and destination tensors. However, it is required that all source tensors are of the same data type (but not necessarily matching the data type of the destination tensor).

Data Representation

The concat primitive does not assign any special meaning associated with any logical dimensions.

Post-ops and Attributes

The concat primitive does not support any post-ops or attributes.

API

```
struct dnnl::concat : public dnnl::primitive
    Tensor concatenation (concat) primitive.
```

Public Functions

```
concat()
    Default constructor. Produces an empty object.
```

```
concat(const primitive_desc &pd)
    Constructs a concatenation primitive.
```

Parameters `pd` – Primitive descriptor for concatenation primitive.

```
struct primitive_desc : public dnnl::primitive_desc_base
    Primitive descriptor for a concat primitive.
```

Public Functions

```
primitive_desc()
    Default constructor. Produces an empty object.
```

```
primitive_desc(const memory::desc &dst, int concat_dimension, const std::vector<memory::desc>
    &srcs, const engine &engine, const primitive_attr &attr = primitive_attr())
```

Constructs a primitive descriptor for an out-of-place concatenation primitive.

Parameters

- `dst` – Destination memory descriptor.

- **concat_dimension** – Source tensors will be concatenated over dimension with this index. Note that order of dimensions does not depend on memory format.
- **srcs** – Vector of source memory descriptors.
- **aengine** – Engine to perform the operation on.
- **attr** – Primitive attributes to use (optional).

primitive_desc(int concat_dimension, const std::vector<memory::desc> &srcs, const engine &aengine, const primitive_attr &attr = primitive_attr())

Constructs a primitive descriptor for an out-of-place concatenation primitive.

This version derives the destination memory descriptor automatically.

Parameters

- **concat_dimension** – Source tensors will be concatenated over dimension with this index. Note that order of dimensions does not depend on memory format.
- **srcs** – Vector of source memory descriptors.
- **aengine** – Engine to perform the operation on.
- **attr** – Primitive attributes to use (optional).

memory::desc **src_desc**(int idx = 0) const

Returns a source memory descriptor.

Parameters **idx** – Source index.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter with index idx.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

5.5.6 Convolution and Deconvolution

The convolution and deconvolution primitives compute forward, backward, or weight update for a batched convolution or deconvolution operations on 1D, 2D, or 3D spatial data with bias.

The operations are defined by the following formulas. We show formulas only for 2D spatial data which are straight-forward to generalize to cases of higher and lower dimensions. Variable names follow the standard *Conventions*.

Forward

Let src, weights and dst be $N \times IC \times IH \times IW$, $OC \times IC \times KH \times KW$, and $N \times OC \times OH \times OW$ tensors respectively. Let bias be a 1D tensor with OC elements.

Furthermore, let the remaining convolution parameters be:

Parameter	Depth	Height	Width	Comment
Padding: Front, top, and left	PD_L	PH_L	PW_L	In the API padding_l indicates the corresponding vector of paddings (_l in the name stands for left)
Padding: Back, bottom, and right	PD_R	PH_R	PW_R	In the API padding_r indicates the corresponding vector of paddings (_r in the name stands for right)
Stride	SD	SH	SW	Convolution without strides is defined by setting the stride parameters to 1
Dilation	DD	DH	DW	Non-dilated convolution is defined by setting the dilation parameters to 0

The following formulas show how oneDNN computes convolutions. They are broken down into several types to simplify the exposition, but in reality the convolution types can be combined.

To further simplify the formulas, we assume that $\text{src}(n, ic, ih, iw) = 0$ if $ih < 0$, or $ih \geq IH$, or $iw < 0$, or $iw \geq IW$.

Regular Convolution

$$\begin{aligned} \text{dst}(n, oc, oh, ow) &= \text{bias}(oc) \\ &+ \sum_{ic=0}^{IC-1} \sum_{kh=0}^{KH-1} \sum_{kw=0}^{KW-1} \text{src}(n, ic, oh', ow') \cdot \text{weights}(oc, ic, kh, kw). \end{aligned}$$

Here:

- $oh' = oh \cdot SH + kh - PH_L$,
- $ow' = ow \cdot SW + kw - PW_L$,
- $OH = \lfloor \frac{IH - KH + PH_L + PH_R}{SH} \rfloor + 1$,
- $OW = \lfloor \frac{IW - KW + PW_L + PW_R}{SW} \rfloor + 1$.

Convolution with Groups

oneDNN adds a separate groups dimension to memory objects representing weights tensors and represents weights as $G \times OC_G \times IC_G \times KH \times KW$ 5D tensors for 2D convolutions with groups.

$$\begin{aligned} \text{dst}(n, g \cdot OC_G + oc_g, oh, ow) &= \text{bias}(g \cdot OC_G + oc_g) \\ &+ \sum_{ic_g=0}^{IC_G-1} \sum_{kh=0}^{KH-1} \sum_{kw=0}^{KW-1} \text{src}(n, g \cdot IC_G + ic_g, oh', ow') \cdot \text{weights}(g, oc_g, ic_g, kh, kw), \end{aligned}$$

where

- $IC_G = \frac{IC}{G}$,
- $OC_G = \frac{OC}{G}$, and
- $oc_g \in [0, OC_G)$.

The case when $OC_G = IC_G = 1$ is also known as a *depthwise convolution*.

Convolution with Dilation

$$\begin{aligned} \text{dst}(n, oc, oh, ow) &= \text{bias}(oc) + \\ &+ \sum_{ic=0}^{IC-1} \sum_{kh=0}^{KH-1} \sum_{kw=0}^{KW-1} \text{src}(n, ic, oh'', ow'') \cdot \text{weights}(oc, ic, kh, kw). \end{aligned}$$

Here:

- $oh'' = oh \cdot SH + kh \cdot (DH + 1) - PH_L$,
- $ow'' = ow \cdot SW + kw \cdot (DW + 1) - PW_L$,

- $OH = \lfloor \frac{IH - DKH + PH_L + PH_R}{SH} \rfloor + 1$, where $DKH = 1 + (KH - 1) \cdot (DH + 1)$, and
- $OW = \lfloor \frac{IW - DKW + PW_L + PW_R}{SW} \rfloor + 1$, where $DKW = 1 + (KW - 1) \cdot (DW + 1)$.

Deconvolution (Transposed Convolution)

Deconvolutions (also called fractionally-strided convolutions or transposed convolutions) can be defined by swapping the forward and backward passes of a convolution. One way to put it is to note that the weights define a convolution, but whether it is a direct convolution or a transposed convolution is determined by how the forward and backward passes are computed.

Difference Between Forward Training and Forward Inference

There is no difference between the *forward_training* and *forward_inference* propagation kinds.

Backward

The backward propagation computes *diff_src* based on *diff_dst* and weights.

The weights update computes *diff_weights* and *diff_bias* based on *diff_dst* and *src*.

Note: The *optimized* memory formats *src* and *weights* might be different on forward propagation, backward propagation, and weights update.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
<i>src</i>	<i>DNLL_ARG_SRC</i>
<i>weights</i>	<i>DNLL_ARG_WEIGHTS</i>
<i>bias</i>	<i>DNLL_ARG_BIAS</i>
<i>dst</i>	<i>DNLL_ARG_DST</i>
<i>diff_src</i>	<i>DNLL_ARG_DIFF_SRC</i>
<i>diff_weights</i>	<i>DNLL_ARG_DIFF_WEIGHTS</i>
<i>diff_bias</i>	<i>DNLL_ARG_DIFF_BIAS</i>
<i>diff_dst</i>	<i>DNLL_ARG_DIFF_DST</i>

Operation Details

N/A

Data Types Support

Convolution primitive supports the following combination of data types for source, destination, and weights memory objects.

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Propagation	Source	Weights	Destination	Bias
forward / backward	<code>f32</code>	<code>f32</code>	<code>f32</code>	<code>f32</code>
forward	<code>f16</code>	<code>f16</code>	<code>f16</code>	<code>f16</code>
forward	<code>u8, s8</code>	<code>s8</code>	<code>u8, s8, s32, f32</code>	<code>u8, s8, s32, f32</code>
forward	<code>bf16</code>	<code>bf16</code>	<code>f32, bf16</code>	<code>f32, bf16</code>
backward	<code>f32, bf16</code>	<code>bf16</code>	<code>bf16</code>	
weights update	<code>bf16</code>	<code>f32, bf16</code>	<code>bf16</code>	<code>f32, bf16</code>

Data Representation

Like other CNN primitives, the convolution primitive expects the following tensors:

Spatial	Source / Destination	Weights
1D	$N \times C \times W$	$[G \times] OC \times IC \times KW$
2D	$N \times C \times H \times W$	$[G \times] OC \times IC \times KH \times KW$
3D	$N \times C \times D \times H \times W$	$[G \times] OC \times IC \times KD \times KH \times KW$

Memory format of data and weights memory objects is critical for convolution primitive performance. In the oneDNN programming model, convolution is one of the few primitives that support the placeholder memory format tag `any` and can define data and weight memory objects format based on the primitive parameters. When using `any` it is necessary to first create a convolution primitive descriptor and then query it for the actual data and weight memory objects formats.

While convolution primitives can be created with memory formats specified explicitly, the performance is likely to be suboptimal.

The table below shows the combinations for which `plain` memory formats the convolution primitive is optimized for.

Spatial	Convolution Type	Data / Weights logical tensor	Implementation optimized for memory formats
1D, 2D, 3D		<i>any</i>	<i>optimized</i>
1D	f32, bf16	NCW / OIW, GOIW	<i>ncw (abc) / oiw (abc), goiw (abcd)</i>
1D	f32, bf16	NCW / OIW, GOIW	<i>nwc (acb) / wio (cba), wigo (dcab)</i>
1D	int8	NCW / OIW	<i>nwc (acb) / wio (cba)</i>
2D	f32, bf16	NCHW / OIHW, GOIHW	<i>nchw (abcd) / oihw (abcd), goihw (abcde)</i>
2D	f32, bf16	NCHW / OIHW, GOIHW	<i>nhwc (acdb) / hwio (cdba), hwigo (decab)</i>
2D	int8	NCHW / OIHW, GOIHW	<i>nhwc (acdb) / hwio (cdba), hwigo (decab)</i>
3D	f32, bf16	NCDHW / OIDHW, GOIDHW	<i>ncdhw (abcde) / oidhw (abcde), goidhw (abcdef)</i>
3D	f32, bf16	NCDHW / OIDHW, GOIDHW	<i>ndhwc (acdeb) / dhwio (cdeba), dhwigo (defcab)</i>
3D	int8	NCDHW / OIDHW	<i>ndhwc (acdeb) / dhwio (cdeba)</i>

Post-ops and Attributes

Post-ops and attributes enable you to modify the behavior of the convolution primitive by applying quantization parameters to the result of the primitive and by chaining certain operations after the primitive. The following attributes and post-ops are supported:

Type	Operation	Description	Restrictions
At-tribute	<i>Scales</i>	Sets scale(s) for the corresponding tensor(s)	Int8 computations only
At-tribute	<i>Zero points</i>	Sets zero point(s) for the corresponding tensors	Int8 computations only
post-op	<i>Eltwise</i>	Applies an elementwise operation to the result	
post-op	<i>Binary</i>	Applies a binary operation to the result	
post-op	<i>Sum</i>	Adds the operation result to the destination tensor instead of overwriting it	

The primitive supports dynamic quantization via run-time scales. That means a user could configure the scales and zero-point attributes at the primitive descriptor creation stage. The user must then provide the scales and zero-points as an additional input memory objects with argument *DNLL_ARG_ATTR_SCALES* and *DNLL_ARG_ATTR_ZERO_POINTS* during the execution stage (more details are provided in the *Quantization* section).

Note: The library does not prevent using post-ops in training, but note that not all post-ops are feasible for training usage. For instance, using ReLU with non-zero negative slope parameter as a post-op would not produce an additional

output workspace that is required to compute backward propagation correctly. Hence, in this particular case one should use separate convolution and eltwise primitives for training.

The following post-ops chaining should be supported by the library:

Type of convolutions	Post-ops sequence supported
f32 and bf16 convolution	eltwise, sum, sum -> eltwise
int8 convolution	eltwise, sum, sum -> eltwise, eltwise -> sum

The operations during attributes and post-ops applying are done in single precision floating point data type. The conversion to the actual destination data type happens just before the actual storing.

Example 1

Consider the following pseudo code:

```
attribute attr;
attr.set_post_ops({
    { sum={scale=beta} },
    { eltwise={scale=gamma, type=tanh, alpha=ignore, beta=ignored }
});

convolution_forward(src, weights, dst, attr)
```

This would lead to the following:

$$\text{dst}(\bar{x}) = \gamma \cdot \tanh(\alpha \cdot \text{conv}(\text{src}, \text{weights}) + \beta \cdot \text{dst}(\bar{x}))$$

Example 2

The following pseudo code:

```
attribute attr;
attr.set_output_scale(alpha);
attr.set_post_ops({
    { eltwise={scale=gamma, type=relu, alpha=eta, beta=ignored }
    { sum={scale=beta} },
});

convolution_forward(src, weights, dst, attr)
```

That would lead to the following:

$$\text{dst}(\bar{x}) = \beta \cdot \text{dst}(\bar{x}) + \gamma \cdot \text{ReLU}(\alpha \cdot \text{conv}(\text{src}, \text{weights}), \eta)$$

Algorithms

oneDNN implementations may implement convolution primitives using several different algorithms which can be chosen by the user.

- *Direct* (`dnnl::algorithm::convolution_direct`). The convolution operation is computed directly using SIMD instructions. This also includes implicit GEMM formulations which notably may require workspace.
- *Winograd* (`dnnl::algorithm::convolution_winograd`). This algorithm reduces computational complexity of convolution at the expense of accuracy loss and additional memory operations. The implementation is based on the [Fast Algorithms for Convolutional Neural Networks](#) by A. Lavin and S. Gray. The Winograd algorithm often results in the best performance, but it is applicable only to particular shapes. Moreover, Winograd only supports int8 and f32 data types.
- *Auto* (`dnnl::algorithm::convolution_auto`). In this case the library should automatically select the *best* algorithm based on the heuristics that take into account tensor shapes and the number of logical processors available.

API

```
struct dnnl::convolution_forward : public dnnl::primitive
    Convolution forward propagation primitive.
```

Public Functions

convolution_forward()

Default constructor. Produces an empty object.

convolution_forward(const *primitive_desc* &pd)

Constructs a convolution forward propagation primitive.

Parameters **pd** – Primitive descriptor for a convolution forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
```

Primitive descriptor for a convolution forward propagation primitive.

Public Functions

primitive_desc()

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_desc, const *memory::dims* &strides, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution forward propagation primitive with bias.

Arrays `strides`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **aalgorithm** – Convolution algorithm. Possible values are `dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`, and `dnnl::algorithm::convolution_auto`.
- **src_desc** – Source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **bias_desc** – Bias memory descriptor. Passing zero memory descriptor disables the bias term.
- **dst_desc** – Destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension (`[[front,] top,] left`).
- **padding_r** – Vector of padding values for high indices for each spatial dimension (`[[back,] bottom,] right`).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &dst_desc, const *memory::dims* &strides, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution forward propagation primitive without bias.

Arrays `strides`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **aalgorithm** – Convolution algorithm. Possible values are `dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`, and `dnnl::algorithm::convolution_auto`.
- **src_desc** – Source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **strides** – Strides for each spatial dimension.

- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution forward propagation primitive with bias.

Arrays *strides*, *dilates*, *padding_l*, and *padding_r* contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **prop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – Convolution algorithm. Possible values are *dnnl::algorithm::convolution_direct*, *dnnl::algorithm::convolution_winograd*, and *dnnl::algorithm::convolution_auto*.
- **src_desc** – Source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **bias_desc** – Bias memory descriptor. Passing zero memory descriptor disables the bias term.
- **dst_desc** – Destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution forward propagation primitive without bias.

Arrays `strides`, `dilates`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **aalgorithm** – Convolution algorithm. Possible values are `dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`, and `dnnl::algorithm::convolution_auto`.
- **src_desc** – Source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension (`[[front,] top,] left`).
- **padding_r** – Vector of padding values for high indices for each spatial dimension (`[[back,] bottom,] right`).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc src_desc()` const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

`memory::desc weights_desc()` const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

`memory::desc dst_desc()` const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

`memory::desc bias_desc()` const

Returns the bias memory descriptor.

Returns The bias memory descriptor.

Returns A zero memory descriptor of the primitive does not have a bias parameter.

`algorithm get_algorithm()` const

Returns an algorithm kind.

Returns An algorithm kind.

Returns `dnnl::algorithm::undef` if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind()** const
Returns a propagation kind.
Returns A propagation kind.
Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

memory::dims **get_strides()** const
Returns strides.
Returns Strides.
Returns An empty *dnnl::memory::dims* if the primitive does not have a strides parameter.

memory::dims **get_dilations()** const
Returns dilations.
Returns Dilations.
Returns An empty *dnnl::memory::dims* if the primitive does not have a dilations parameter.

memory::dims **get_padding_l()** const
Returns a left padding.
Returns A left padding.
Returns An empty *dnnl::memory::dims* if the primitive does not have a left padding parameter.

memory::dims **get_padding_r()** const
Returns a right padding.
Returns A right padding.
Returns An empty *dnnl::memory::dims* if the primitive does not have a right padding parameter.

struct **dnnl::convolution_backward_data** : public *dnnl::primitive*
Convolution backward propagation primitive.

Public Functions

convolution_backward_data()
Default constructor. Produces an empty object.

convolution_backward_data(const *primitive_desc* &pd)
Constructs a convolution backward propagation primitive.
Parameters **pd** – Primitive descriptor for a convolution backward propagation primitive.

struct **primitive_desc** : public *dnnl::primitive_desc*
Primitive descriptor for a convolution backward propagation primitive.

Public Functions

primitive_desc()
Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &diff_src_desc, const *memory::desc* &weights_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *convolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)
Constructs a primitive descriptor for a convolution backward propagation primitive.

Arrays `strides`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Convolution algorithm. Possible values are `dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`, and `dnnl::algorithm::convolution_auto`.
- **diff_src_desc** – Diff source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a convolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &diff_src_desc, const *memory::desc* &weights_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *convolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution backward propagation primitive.

Arrays `strides`, `dilates`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Convolution algorithm. Possible values are `dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`, and `dnnl::algorithm::convolution_auto`.
- **diff_src_desc** – Diff source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.

- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a convolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **diff_src_desc()** const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **weights_desc()** const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **diff_dst_desc()** const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

algorithm **get_algorithm()** const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

memory::dims **get_strides()** const

Returns strides.

Returns Strides.

Returns An empty *dnnl::memory::dims* if the primitive does not have a strides parameter.

memory::dims **get_dilations()** const

Returns dilations.

Returns Dilations.

Returns An empty *dnnl::memory::dims* if the primitive does not have a dilations parameter.

memory::dims **get_padding_l()** const

Returns a left padding.

Returns A left padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a left padding parameter.

memory::dims **get_padding_r()** const

Returns a right padding.

Returns A right padding.

Returns An empty `dnnl::memory::dims` if the primitive does not have a right padding parameter.

```
struct dnnl::convolution_backward_weights : public dnnl::primitive
    Convolution weights gradient primitive.
```

Public Functions

convolution_backward_weights()

Default constructor. Produces an empty object.

convolution_backward_weights(const primitive_desc &pd)

Constructs a convolution weights gradient primitive.

Parameters **pd** – Primitive descriptor for a convolution weights gradient primitive.

```
struct primitive_desc : public dnnl::primitive_desc
```

Primitive descriptor for a convolution weights gradient primitive.

Public Functions

primitive_desc()

Default constructor. Produces an empty object.

primitive_desc(const engine &aengine, algorithm aalgorithm, const memory::desc &src_desc, const memory::desc &diff_weights_desc, const memory::desc &diff_bias_desc, const memory::desc &diff_dst_desc, const memory::dims &strides, const memory::dims &padding_l, const memory::dims &padding_r, const convolution_forward::primitive_desc &hint_fwd_pd, const primitive_attr &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution weights gradient primitive with bias.

Arrays `strides`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Convolution algorithm. Possible values are `dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`, and `dnnl::algorithm::convolution_auto`.
- **src_desc** – Source memory descriptor.
- **diff_weights_desc** – Diff weights memory descriptor.
- **diff_bias_desc** – Diff bias memory descriptor. Passing zero memory descriptor disables the bias term.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension (`[[front,] top,] left`).

- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a convolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *convolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution weights gradient primitive without bias.

Arrays *strides*, *padding_l*, and *padding_r* contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Convolution algorithm. Possible values are *dnnl::algorithm::convolution_direct*, *dnnl::algorithm::convolution_winograd*, and *dnnl::algorithm::convolution_auto*.
- **src_desc** – Source memory descriptor.
- **diff_weights_desc** – Diff weights memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a convolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *convolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution weights gradient primitive with bias.

Arrays *strides*, *dilates*, *padding_l*, and *padding_r* contain values for spatial dimensions only

and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Convolution algorithm. Possible values are `dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`, and `dnnl::algorithm::convolution_auto`.
- **src_desc** – Source memory descriptor.
- **diff_weights_desc** – Diff weights memory descriptor.
- **diff_bias_desc** – Diff bias memory descriptor. Passing zero memory descriptor disables the bias term.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a convolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *convolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a convolution weights gradient primitive without bias.

Arrays `strides`, `dilates`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Convolution algorithm. Possible values are `dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`, and `dnnl::algorithm::convolution_auto`.
- **src_desc** – Source memory descriptor.

- **diff_weights_desc** – Diff weights memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a convolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc()** const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **diff_weights_desc()** const

Returns a diff weights memory descriptor.

Returns Diff weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff weights parameter.

memory::desc **diff_dst_desc()** const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

memory::desc **diff_bias_desc()** const

Returns the diff bias memory descriptor.

Returns The diff bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff bias parameter.

algorithm **get_algorithm()** const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

memory::dims **get_strides()** const

Returns strides.

Returns Strides.

Returns An empty *dnnl::memory::dims* if the primitive does not have a strides parameter.

memory::dims **get_dilations()** const

Returns dilations.

Returns Dilations.

Returns An empty *dnnl::memory::dims* if the primitive does not have a dilations parameter.

memory::dims **get_padding_l()** const

Returns a left padding.

Returns A left padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a left padding parameter.

memory::dims **get_padding_r()** const

Returns a right padding.

Returns A right padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a right padding parameter.

struct **dnnl::deconvolution_forward** : public *dnnl::primitive*
Deconvolution forward propagation primitive.

Public Functions

deconvolution_forward()

Default constructor. Produces an empty object.

deconvolution_forward(const *primitive_desc* &pd)

Constructs a deconvolution forward propagation primitive.

Parameters **pd** – Primitive descriptor for a deconvolution forward propagation primitive.

struct **primitive_desc** : public *dnnl::primitive_desc*
Primitive descriptor for a deconvolution forward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_desc, const *memory::dims* &strides, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution forward propagation primitive with bias.

Arrays **strides**, **padding_l**, and **padding_r** contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of **format_tag**.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – Deconvolution algorithm: *dnnl::algorithm::deconvolution_direct*, and *dnnl::algorithm::deconvolution_winograd*.
- **src_desc** – Source memory descriptor.

- **weights_desc** – Weights memory descriptor.
- **bias_desc** – Bias memory descriptor. Passing zero memory descriptor disables the bias term.
- **dst_desc** – Destination memory descriptor.
- **strides** – Vector of strides for spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &dst_desc, const *memory::dims* &strides, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution forward propagation primitive without bias.

Arrays `strides`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **aalgorithm** – Deconvolution algorithm: `dnnl::algorithm::deconvolution_direct`, and `dnnl::algorithm::deconvolution_winograd`.
- **src_desc** – Source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **strides** – Vector of strides for spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution forward propagation primitive with bias.

Arrays `strides`, `dilates`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **aalgorithm** – Deconvolution algorithm: `dnnl::algorithm::deconvolution_direct`, and `dnnl::algorithm::deconvolution_winograd`.
- **src_desc** – Source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **bias_desc** – Bias memory descriptor. Passing zero memory descriptor disables the bias term.
- **dst_desc** – Destination memory descriptor.
- **strides** – Vector of strides for spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension (`[[front,] top,] left`).
- **padding_r** – Vector of padding values for high indices for each spatial dimension (`[[back,] bottom,] right`).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

```
primitive_desc(const engine &aengine, prop_kind aprop_kind, algorithm aalgorithm, const
    memory::desc &src_desc, const memory::desc &weights_desc, const memory::desc
    &dst_desc, const memory::dims &strides, const memory::dims &dilates, const
    memory::dims &padding_l, const memory::dims &padding_r, const primitive_attr
    &attr = default_attr(), bool allow_empty = false)
```

Constructs a primitive descriptor for a deconvolution forward propagation primitive without bias.

Arrays `strides`, `dilates`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **aalgorithm** – Deconvolution algorithm: `dnnl::algorithm::deconvolution_direct`, and `dnnl::algorithm::deconvolution_winograd`.

- **src_desc** – Source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **strides** – Vector of strides for spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **weights_desc**() const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

memory::desc **bias_desc**() const

Returns the bias memory descriptor.

Returns The bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

algorithm **get_algorithm**() const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind**() const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

memory::dims **get_strides**() const

Returns strides.

Returns Strides.

Returns An empty *dnnl::memory::dims* if the primitive does not have a strides parameter.

memory::dims **get_dilations**() const

Returns dilations.

Returns Dilations.

Returns An empty *dnnl::memory::dims* if the primitive does not have a dilations parameter.

memory::dims **get_padding_l**() const

Returns a left padding.

Returns A left padding.

Returns An empty `dnnl::memory::dims` if the primitive does not have a left padding parameter.

`memory::dims` **get_padding_r()** const

Returns a right padding.

Returns A right padding.

Returns An empty `dnnl::memory::dims` if the primitive does not have a right padding parameter.

struct `dnnl::deconvolution_backward_data` : public `dnnl::primitive`
Deconvolution backward propagation primitive.

Public Functions

deconvolution_backward_data()

Default constructor. Produces an empty object.

deconvolution_backward_data(const `primitive_desc` &pd)

Constructs a deconvolution backward propagation primitive.

Parameters `pd` – Primitive descriptor for a deconvolution backward propagation primitive.

struct **primitive_desc** : public `dnnl::primitive_desc`

Primitive descriptor for a deconvolution backward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const `engine` &aengine, `algorithm` aalgorithm, const `memory::desc` &diff_src_desc, const `memory::desc` &weights_desc, const `memory::desc` &diff_dst_desc, const `memory::dims` &strides, const `memory::dims` &padding_l, const `memory::dims` &padding_r, const `deconvolution_forward::primitive_desc` &hint_fwd_pd, const `primitive_attr` &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution backward propagation primitive.

Arrays `strides`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Deconvolution algorithm (`dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`).
- **diff_src_desc** – Diff source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.

- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a deconvolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &diff_src_desc, const *memory::desc* &weights_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *deconvolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution backward propagation primitive.

Arrays `strides`, `dilates`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Deconvolution algorithm (`dnnl::algorithm::convolution_direct`, `dnnl::algorithm::convolution_winograd`).
- **diff_src_desc** – Diff source memory descriptor.
- **weights_desc** – Weights memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a deconvolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **diff_src_desc**() const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **weights_desc()** const
Returns a weights memory descriptor.
Returns Weights memory descriptor.
Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **diff_dst_desc()** const
Returns a diff destination memory descriptor.
Returns Diff destination memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

algorithm **get_algorithm()** const
Returns an algorithm kind.
Returns An algorithm kind.
Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind()** const
Returns a propagation kind.
Returns A propagation kind.
Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

memory::dims **get_strides()** const
Returns strides.
Returns Strides.
Returns An empty *dnnl::memory::dims* if the primitive does not have a strides parameter.

memory::dims **get_dilations()** const
Returns dilations.
Returns Dilations.
Returns An empty *dnnl::memory::dims* if the primitive does not have a dilations parameter.

memory::dims **get_padding_l()** const
Returns a left padding.
Returns A left padding.
Returns An empty *dnnl::memory::dims* if the primitive does not have a left padding parameter.

memory::dims **get_padding_r()** const
Returns a right padding.
Returns A right padding.
Returns An empty *dnnl::memory::dims* if the primitive does not have a right padding parameter.

struct **dnnl::deconvolution_backward_weights** : public *dnnl::primitive*
Deconvolution weights gradient primitive.

Public Functions

deconvolution_backward_weights()
Default constructor. Produces an empty object.

deconvolution_backward_weights(const *primitive_desc* &pd)
Constructs a deconvolution weights gradient primitive.

Parameters **pd** – Primitive descriptor for a deconvolution weights gradient primitive.

struct **primitive_desc** : public *dnnl::primitive_desc*
Primitive descriptor for a deconvolution weights gradient primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *deconvolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution weights gradient primitive with bias.

Arrays *strides*, *padding_l*, and *padding_r* contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Deconvolution algorithm. Possible values are *dnnl::algorithm::deconvolution_direct*, and *dnnl::algorithm::deconvolution_winograd*.
- **src_desc** – Source memory descriptor.
- **diff_weights_desc** – Diff weights memory descriptor.
- **diff_bias_desc** – Diff bias memory descriptor. Passing zero memory descriptor disables the bias term.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a deconvolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *deconvolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution weights gradient primitive without bias.

Arrays *strides*, *padding_l*, and *padding_r* contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Deconvolution algorithm. Possible values are `dnnl::algorithm::deconvolution_direct`, and `dnnl::algorithm::deconvolution_winograd`.
- **src_desc** – Source memory descriptor.
- **diff_weights_desc** – Diff weights memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension (`[[front,] top,] left`).
- **padding_r** – Vector of padding values for high indices for each spatial dimension (`[[back,] bottom,] right`).
- **hint_fwd_pd** – Primitive descriptor for a deconvolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *deconvolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution weights gradient primitive with bias.

Arrays `strides`, `dilates`, `padding_l`, and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Deconvolution algorithm. Possible values are `dnnl::algorithm::deconvolution_direct`, and `dnnl::algorithm::deconvolution_winograd`.
- **src_desc** – Source memory descriptor.
- **diff_weights_desc** – Diff weights memory descriptor.
- **diff_bias_desc** – Diff bias memory descriptor. Passing zero memory descriptor disables the bias term.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension (`[[front,] top,] left`).

- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a deconvolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &engine, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_dst_desc, const *memory::dims* &strides, const *memory::dims* &dilates, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *deconvolution_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a deconvolution weights gradient primitive without bias.

Arrays *strides*, *dilates*, *padding_l*, and *padding_r* contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **engine** – Engine to use.
- **aalgorithm** – Deconvolution algorithm. Possible values are *dnnl::algorithm::deconvolution_direct*, and *dnnl::algorithm::deconvolution_winograd*.
- **src_desc** – Source memory descriptor.
- **diff_weights_desc** – Diff weights memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Strides for each spatial dimension.
- **dilates** – Dilations for each spatial dimension. A zero value means no dilation in the corresponding dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a deconvolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **diff_weights_desc**() const

Returns a diff weights memory descriptor.

Returns Diff weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff weights parameter.

memory::desc **diff_dst_desc**() const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

memory::desc **diff_bias_desc**() const

Returns the diff bias memory descriptor.

Returns The diff bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff bias parameter.

algorithm **get_algorithm**() const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind**() const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

memory::dims **get_strides**() const

Returns strides.

Returns Strides.

Returns An empty *dnnl::memory::dims* if the primitive does not have a strides parameter.

memory::dims **get_dilations**() const

Returns dilations.

Returns Dilations.

Returns An empty *dnnl::memory::dims* if the primitive does not have a dilations parameter.

memory::dims **get_padding_l**() const

Returns a left padding.

Returns A left padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a left padding parameter.

memory::dims **get_padding_r**() const

Returns a right padding.

Returns A right padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a right padding parameter.

5.5.7 Elementwise

The elementwise primitive applies an operation to every element of the tensor. Variable names follow the standard *Conventions*.

$$\text{dst}(\bar{x}) = \text{Operation}(\text{src}(\bar{x})),$$

for $\bar{x} = (x_0, \dots, x_n)$.

Forward

The following forward operations are supported. Here s and d denote src and dst, tensor values respectively.

Elementwise algorithm	Forward formula
<code>eltwise_abs</code>	$d = \begin{cases} s & \text{if } s > 0 \\ -s & \text{if } s \leq 0 \end{cases}$
<code>eltwise_clip, eltwise_clip_use_dst_for_bwd</code>	$d = \begin{cases} \beta & \text{if } s > \beta \geq \alpha \\ s & \text{if } \alpha < s \leq \beta \\ \alpha & \text{if } s \leq \alpha \end{cases}$
<code>eltwise_elu, eltwise_elu_use_dst_for_bwd</code>	$d = \begin{cases} s & \text{if } s > 0 \\ \alpha(e^s - 1) & \text{if } s \leq 0 \end{cases}$
<code>eltwise_exp, eltwise_exp_use_dst_for_bwd</code>	$d = e^s$
<code>eltwise_gelu_erf</code>	$d = 0.5s(1 + \operatorname{erf}[\frac{s}{\sqrt{2}}])$
<code>eltwise_gelu_tanh</code>	$d = 0.5s(1 + \operatorname{tanh}[\sqrt{\frac{2}{\pi}}(s + 0.044715s^3)])$
<code>eltwise_hardsigmoid</code>	$d = \max(0, \min(1, \alpha s + \beta))$
<code>eltwise_hardswish</code>	$d = s \cdot \operatorname{hardsigmoid}(s)$
<code>eltwise_linear</code>	$d = \alpha s + \beta$
<code>eltwise_log</code>	$d = \log_e s$
<code>eltwise_logistic, eltwise_logistic_use_dst_for_bwd</code>	$d = \frac{1}{1+e^{-s}}$
<code>eltwise_mish</code>	$d = s \cdot \operatorname{tanh}(\log_e(1 + e^s))$
<code>eltwise_pow</code>	$d = \alpha s^\beta$
<code>eltwise_relu, eltwise_relu_use_dst_for_bwd</code>	$d = \begin{cases} s & \text{if } s > 0 \\ \alpha s & \text{if } s \leq 0 \end{cases}$
<code>eltwise_round</code>	$d = \operatorname{round}(s)$
<code>eltwise_soft_relu</code>	$d = \frac{1}{\alpha} \log_e(1 + e^{\alpha s})$
<code>eltwise_sqrt, eltwise_sqrt_use_dst_for_bwd</code>	$d = \sqrt{s}$
<code>eltwise_square</code>	$d = s^2$
<code>eltwise_swish</code>	$d = \frac{s}{1+e^{-\alpha s}}$
<code>eltwise_tanh, eltwise_tanh_use_dst_for_bwd</code>	$d = \operatorname{tanh} s$

Backward

The backward propagation computes $\operatorname{diff_src}(\bar{s})$, based on $\operatorname{diff_dst}(\bar{s})$ and $\operatorname{src}(\bar{s})$. However, some operations support a computation using $\operatorname{dst}(\bar{s})$ memory produced during forward propagation. Refer to the table above for a list of operations supporting destination as input memory and the corresponding formulas.

The following backward operations are supported. Here s , d , ds and dd denote src, dst, diff_src, and a diff_dst tensor values respectively.

Elementwise algorithm	Backward formula
<code>eltwise_abs</code>	$ds = \begin{cases} dd & \text{if } s > 0 \\ -dd & \text{if } s < 0 \\ 0 & \text{if } s = 0 \end{cases}$
<code>eltwise_clip</code>	$ds = \begin{cases} dd & \text{if } \alpha < s < \beta \\ 0 & \text{otherwise} \end{cases}$
<code>eltwise_clip_used_for_bwd</code>	$ds = \begin{cases} dd & \text{if } \alpha < d < \beta \\ 0 & \text{otherwise} \end{cases}$
<code>eltwise_elu</code>	$ds = \begin{cases} dd & \text{if } s > 0 \\ dd \cdot \alpha e^s & \text{if } s \leq 0 \end{cases}$
<code>eltwise_elu_used_for_bwd</code>	$ds = \begin{cases} dd & \text{if } d > 0 \\ dd \cdot (d + \alpha) & \text{if } d \leq 0 \end{cases}$ only if $\alpha \geq 0$
<code>eltwise_exp</code>	$ds = dd \cdot e^s$
<code>eltwise_exp_used_for_bwd</code>	$ds = dd \cdot e^s$
<code>eltwise_gelu_erf</code>	$ds = dd \cdot \left(0.5 + 0.5 \operatorname{erf}\left(\frac{s}{\sqrt{2}}\right) + \frac{s}{\sqrt{2\pi}} e^{-0.5s^2}\right)$
<code>eltwise_gelu_tanh</code>	$ds = dd \cdot \left(0.5(1 + \tanh[\sqrt{\frac{2}{\pi}}(s + 0.044715s^3)]) \cdot (1 + \sqrt{\frac{2}{\pi}}(s + 0.134145s^3)) \cdot (1 - \tanh[\sqrt{\frac{2}{\pi}}(s + 0.044715s^3)])\right)$
<code>eltwise_hardsigmoid</code>	$ds = \begin{cases} dd \cdot \alpha & \text{if } 0 < \alpha s + \beta < 1 \\ 0 & \text{otherwise} \end{cases}$
<code>eltwise_hardswish</code>	$ds = \begin{cases} dd \cdot (2\alpha + \beta) & \text{if } 0 < \alpha s + \beta < 1 \\ dd & \text{if } \alpha \cdot s + \beta \geq 1 \\ 0 & \text{otherwise} \end{cases}$
<code>eltwise_linear</code>	$ds = \alpha \cdot dd$
<code>eltwise_log</code>	$ds = \frac{dd}{s}$
<code>eltwise_logistic</code>	$ds = \frac{dd}{1+e^{-s}} \cdot \left(1 - \frac{1}{1+e^{-s}}\right)$
<code>eltwise_mish</code>	$ds = dd \cdot \frac{e^s \cdot \omega}{\delta^2}$ with $\omega = e^{3s} + 4 \cdot e^{2s} + e^s \cdot (4 \cdot s + 6) + 4 \cdot (s + 1)$ and $\delta = e^{2s} + 2 \cdot e^s + 2$
<code>eltwise_logistic_used_for_bwd</code>	$ds = dd \cdot \frac{1}{1+e^{-s}}$
<code>eltwise_pow</code>	$ds = dd \cdot \alpha \beta s^{\beta-1}$
<code>eltwise_relu</code>	$ds = \begin{cases} dd & \text{if } s > 0 \\ \alpha \cdot dd & \text{if } s \leq 0 \end{cases}$
<code>eltwise_relu_used_for_bwd</code>	$ds = \begin{cases} dd & \text{if } d > 0 \\ \alpha \cdot dd & \text{if } d \leq 0 \end{cases}$ only if $\alpha \geq 0$
<code>eltwise_soft_relu</code>	$ds = \frac{dd}{1+e^{-\alpha s}}$
<code>eltwise_sqrt</code>	$ds = \frac{dd}{2\sqrt{s}}$
<code>eltwise_sqrt_used_for_bwd</code>	$ds = \frac{dd}{2\sqrt{s}}$
<code>eltwise_square</code>	$ds = dd \cdot 2s$
<code>eltwise_swish</code>	$ds = \frac{dd}{1+e^{-\alpha s}} \left(1 + \alpha s \left(1 - \frac{1}{1+e^{-\alpha s}}\right)\right)$
<code>eltwise_tanh</code>	$ds = dd \cdot (1 - \tanh^2 s)$
<code>eltwise_tanh_used_for_bwd</code>	$ds = dd \cdot (1 - \tanh^2 s)$

Difference Between Forward Training and Forward Inference

There is no difference between the `#dnnl_forward_training` and `#dnnl_forward_inference` propagation kinds.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
<code>src</code>	<code>DNNL_ARG_SRC</code>
<code>dst</code>	<code>DNNL_ARG_DST</code>
<code>diff_src</code>	<code>DNNL_ARG_DIFF_SRC</code>
<code>diff_dst</code>	<code>DNNL_ARG_DIFF_DST</code>

Operation Details

1. The `dnnl::eltwise_forward::primitive_desc` and `dnnl::eltwise_backward::primitive_desc` constructors take both parameters α , and β . These parameters are ignored if they are unused by the algorithm.
2. The memory format and data type for `src` and `dst` are assumed to be the same. The same holds for `diff_src` and `diff_dst`.
3. Both forward and backward propagation support in-place operations, meaning that `src` can be used as input and output for forward propagation, and `diff_dst` can be used as input and output for backward propagation. In case of an in-place operation, the original data will be overwritten. Note, however, that some algorithms for backward propagation require original `src`, hence the corresponding forward propagation should not be performed in-place for those algorithms. Algorithms that use `dst` for backward propagation can be safely done in-place.
4. For some operations it might be beneficial to compute backward propagation based on `dst(\bar{s})`, rather than on `src(\bar{s})`, for improved performance.

Note: For operations supporting destination memory as input, `dst` can be used instead of `src` when backward propagation is computed. This enables several performance optimizations (see the tips below).

Data Type Support

The `eltwise` primitive should support the following combinations of data types.

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Propagation	Source / Destination	Intermediate data type
forward / backward	<code>f32</code> , <code>bf16</code>	<code>f32</code>
forward	<code>f16</code>	<code>f16</code>
forward	<code>s32</code> / <code>s8</code> / <code>u8</code>	<code>f32</code>

Here the intermediate data type means that the values coming in are first converted to the intermediate data type, then the operation is applied, and finally the result is converted to the output data type.

Data Representation

The eltwise primitive works with arbitrary data tensors. There is no special meaning associated with any logical dimensions.

Post-ops and Attributes

Type	Operation	Description	Restrictions
Post-op	<i>Binary</i>	Applies a binary operation to the result	

API

```
struct dnnl::eltwise_forward : public dnnl::primitive
    Elementwise unary operation forward propagation primitive.
```

Public Functions

eltwise_forward()

Default constructor. Produces an empty object.

eltwise_forward(const primitive_desc &pd)

Constructs an eltwise forward propagation primitive.

Parameters **pd** – Primitive descriptor for an eltwise forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
    Primitive descriptor for an elementwise forward propagation primitive.
```

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const engine &aengine, prop_kind aprop_kind, algorithm aalgorithm, const memory::desc &src_desc, const memory::desc &dst_desc, const primitive_attr &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an elementwise forward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **aalgorithm** – Elementwise algorithm kind.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, float alpha, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an elementwise forward propagation primitive with an alpha parameter.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – Elementwise algorithm kind.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **alpha** – The alpha parameter for the elementwise operation. Specific meaning depends on the algorithm.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, float alpha, float beta, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an elementwise forward propagation primitive with an alpha and beta parameters.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – Elementwise algorithm kind.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **alpha** – The alpha parameter for the elementwise operation. Specific meaning depends on the algorithm.
- **beta** – The beta parameter for the elementwise operation. Specific meaning depends on the algorithm.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

dnnl::algorithm **get_algorithm**() const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

`dnnl::prop_kind` **get_prop_kind**() const
Returns a propagation kind.
Returns A propagation kind.
Returns `dnnl::prop_kind::undef` if the primitive does not have a propagation parameter.

float **get_alpha**() const
Returns an alpha.
Returns An alpha.
Returns Zero if the primitive does not have an alpha parameter.

float **get_beta**() const
Returns a beta.
Returns A beta.
Returns Zero if the primitive does not have a beta parameter.

struct `dnnl::eltwise_backward` : public `dnnl::primitive`
Elementwise unary operation backward propagation primitive.

See also:

eltwise_forward

Public Functions

eltwise_backward()
Default constructor. Produces an empty object.

eltwise_backward(const *primitive_desc* &pd)
Constructs an eltwise backward propagation primitive.

Parameters `pd` – Primitive descriptor for an eltwise backward propagation primitive.

struct **primitive_desc** : public `dnnl::primitive_desc`
Primitive descriptor for eltwise backward propagation.

Public Functions

primitive_desc() = default
Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_dst_desc, const *memory::desc* &data_desc, const *eltwise_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an elementwise backward propagation primitive with an alpha parameter.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Elementwise algorithm kind.
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **data_desc** – Destination memory descriptor if one of the “use_dst_for_bwd” algorithms are used (such as `dnnl::algorithm::eltwise_relu_use_dst_for_bwd`), source memory descriptor otherwise.

- **hint_fwd_pd** – Primitive descriptor for an elementwise forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_dst_desc, const *memory::desc* &data_desc, float alpha, const *eltwise_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an elementwise backward propagation primitive with an alpha parameter.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Elementwise algorithm kind.
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **data_desc** – Destination memory descriptor if one of the “use_dst_for_bwd” algorithms are used (such as *dnnl::algorithm::eltwise_relu_use_dst_for_bwd*), source memory descriptor otherwise.
- **alpha** – The alpha parameter for the elementwise operation. Specific meaning depends on the algorithm.
- **hint_fwd_pd** – Primitive descriptor for an elementwise forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_dst_desc, const *memory::desc* &data_desc, float alpha, float beta, const *eltwise_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an elementwise backward propagation primitive with an alpha and beta parameters.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Elementwise algorithm kind.
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **data_desc** – Destination memory descriptor if one of the “use_dst_for_bwd” algorithms are used (such as *dnnl::algorithm::eltwise_relu_use_dst_for_bwd*), source memory descriptor otherwise.
- **alpha** – The alpha parameter for the elementwise operation. Specific meaning depends on the algorithm.
- **beta** – The beta parameter for the elementwise operation. Specific meaning depends on the algorithm.
- **hint_fwd_pd** – Primitive descriptor for an elementwise forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc()** const
Returns a source memory descriptor.
Returns Source memory descriptor.
Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **diff_src_desc()** const
Returns a diff source memory descriptor.
Returns Diff source memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **diff_dst_desc()** const
Returns a diff destination memory descriptor.
Returns Diff destination memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

dnnl::algorithm **get_algorithm()** const
Returns an algorithm kind.
Returns An algorithm kind.
Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

dnnl::prop_kind **get_prop_kind()** const
Returns a propagation kind.
Returns A propagation kind.
Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

float **get_alpha()** const
Returns an alpha.
Returns An alpha.
Returns Zero if the primitive does not have an alpha parameter.

float **get_beta()** const
Returns a beta.
Returns A beta.
Returns Zero if the primitive does not have a beta parameter.

5.5.8 Inner Product

The inner product primitive (sometimes called *fully connected layer*) treats each activation in the minibatch as a vector and computes its product with a weights 2D tensor producing a 2D tensor as an output.

Forward

Let *src*, *weights*, *bias* and *dst* be $N \times IC$, $OC \times IC$, OC , and $N \times OC$ tensors, respectively. Variable names follow the standard *Conventions*. Then:

$$\text{dst}(n, oc) = \text{bias}(oc) + \sum_{ic=0}^{IC-1} \text{src}(n, ic) \cdot \text{weights}(oc, ic)$$

In cases where the *src* and *weights* tensors have spatial dimensions, they are flattened to 2D. For example, if they are 4D $N \times IC' \times IH \times IW$ and $OC \times IC' \times KH \times KW$ tensors, then the formula above is applied with $IC = IC' \cdot IH \cdot IW$. In such cases, the *src* and *weights* tensors must have equal spatial dimensions (e.g. $KH = IH$ and $KW = IW$ for 4D tensors).

Difference Between Forward Training and Forward Inference

There is no difference between the *forward_training* and *forward_inference* propagation kinds.

Backward

The backward propagation computes *diff_src* based on *diff_dst* and weights.

The weights update computes *diff_weights* and *diff_bias* based on *diff_dst* and *src*.

Note: The *optimized* memory formats *src* and *weights* might be different on forward propagation, backward propagation, and weights update.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
<i>src</i>	<i>DNNL_ARG_SRC</i>
<i>weights</i>	<i>DNNL_ARG_WEIGHTS</i>
<i>bias</i>	<i>DNNL_ARG_BIAS</i>
<i>dst</i>	<i>DNNL_ARG_DST</i>
<i>diff_src</i>	<i>DNNL_ARG_DIFF_SRC</i>
<i>diff_weights</i>	<i>DNNL_ARG_DIFF_WEIGHTS</i>
<i>diff_bias</i>	<i>DNNL_ARG_DIFF_BIAS</i>
<i>diff_dst</i>	<i>DNNL_ARG_DIFF_DST</i>

Operation Details

N/A

Data Types Support

Inner product primitive supports the following combination of data types for source, destination, weights, and bias.

Note: Here we abbreviate data types names for readability. For example, *dnnl::memory::data_type::f32* is abbreviated to *f32*.

Propagation	Source	Weights	Destination	Bias
forward / backward	<i>f32</i>	<i>f32</i>	<i>f32</i>	<i>f32</i>
forward	<i>f16</i>	<i>f16</i>	<i>f16</i>	<i>f16</i>
forward	<i>u8, s8</i>	<i>s8</i>	<i>u8, s8, s32, f32</i>	<i>u8, s8, s32, f32</i>
forward	<i>bf16</i>	<i>bf16</i>	<i>f32, bf16</i>	<i>f32, bf16</i>
backward	<i>f32, bf16</i>	<i>bf16</i>	<i>bf16</i>	
weights update	<i>bf16</i>	<i>f32, bf16</i>	<i>bf16</i>	<i>f32, bf16</i>

Data Representation

Like other CNN primitives, the inner product primitive expects the following tensors:

Spatial	Source	Destination	Weights
1D	$N \times C \times W$	$N \times C$	$OC \times IC \times KW$
2D	$N \times C \times H \times W$	$N \times C$	$OC \times IC \times KH \times KW$
3D	$N \times C \times D \times H \times W$	$N \times C$	$OC \times IC \times KD \times KH \times KW$

Memory format of data and weights memory objects is critical for inner product primitive performance. In the oneDNN programming model, inner product primitive is one of the few primitives that support the placeholder format *any* and can define data and weight memory objects formats based on the primitive parameters. When using *any* it is necessary to first create an inner product primitive descriptor and then query it for the actual data and weight memory objects formats.

The table below shows the combinations for which **plain** memory formats the inner product primitive is optimized for. For the destination tensor (which is always $N \times C$) the memory format is always *nc (ab)*.

Spatial	Source / Weights logical tensor	Implementation optimized for memory formats
0D	NC / OI	<i>nc (ab) / oi (ab)</i>
0D	NC / OI	<i>nc (ab) / io (ba)</i>
1D	NCW / OIW	<i>ncw (abc) / oiw (abc)</i>
1D	NCW / OIW	<i>nwc (acb) / wio (cba)</i>
2D	NCHW / OIHW	<i>nchw (abcd) / oihw (abcd)</i>
2D	NCHW / OIHW	<i>nhwc (acdb) / hwio (cdba)</i>
3D	NCDHW / OIDHW	<i>ncdhw (abcde) / oidhw (abcde)</i>
3D	NCDHW / OIDHW	<i>ndhwc (acdeb) / dhwio (cdeba)</i>

Post-ops and Attributes

The following post-ops should be supported by inner product primitives:

Type	Operation	Description	Restrictions
At-tribute	<i>Scales</i>	Sets scale(s) for the corresponding tensor(s)	Int8 computations only
At-tribute	<i>Zero points</i>	Sets zero point(s) for the corresponding tensors	Int8 computations only
Post-op	<i>Eltwise</i>	Applies an elementwise operation to the result	
Post-op	<i>Binary</i>	Applies a binary operation to the result	
Post-op	<i>Sum</i>	Adds the operation result to the destination tensor instead of over-writing it	

API

struct `dnnl::inner_product_forward` : public `dnnl::primitive`
 Inner product forward propagation primitive.

Public Functions

`inner_product_forward()`

Default constructor. Produces an empty object.

`inner_product_forward(const primitive_desc &pd)`

Constructs an inner product forward propagation primitive.

Parameters `pd` – Primitive descriptor for an inner product forward propagation primitive.

struct `primitive_desc` : public `dnnl::primitive_desc`

Primitive descriptor for an inner product forward propagation primitive.

Public Functions

`primitive_desc()` = default

Default constructor. Produces an empty object.

`primitive_desc(const engine &aengine, prop_kind aprop_kind, const memory::desc &src_desc, const memory::desc &weights_desc, const memory::desc &bias_desc, const memory::desc &dst_desc, const primitive_attr &attr = default_attr(), bool allow_empty = false)`

Constructs a primitive descriptor for an inner product forward propagation primitive with bias.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **src_desc** – Memory descriptor for src.
- **weights_desc** – Memory descriptor for weights.
- **bias_desc** – Memory descriptor for bias.
- **dst_desc** – Memory descriptor for dst.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`primitive_desc(const engine &aengine, prop_kind aprop_kind, const memory::desc &src_desc, const memory::desc &weights_desc, const memory::desc &dst_desc, const primitive_attr &attr = default_attr(), bool allow_empty = false)`

Constructs a primitive descriptor for an inner product forward propagation primitive.

Note: All the memory descriptors may be initialized with the `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **src_desc** – Memory descriptor for src.
- **weights_desc** – Memory descriptor for weights.
- **dst_desc** – Memory descriptor for dst.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc src_desc()` const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

`memory::desc weights_desc()` const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

`memory::desc dst_desc()` const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

`memory::desc bias_desc()` const

Returns the bias memory descriptor.

Returns The bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

`prop_kind get_prop_kind()` const

Returns a propagation kind.

Returns A propagation kind.

Returns `dnnl::prop_kind::undef` if the primitive does not have a propagation parameter.

struct `dnnl::inner_product_backward_data` : public `dnnl::primitive`

Inner product backward propagation primitive.

Public Functions

`inner_product_backward_data()`

Default constructor. Produces an empty object.

`inner_product_backward_data(const primitive_desc &pd)`

Constructs an inner product backward propagation primitive.

Parameters `pd` – Primitive descriptor for an inner product backward propagation primitive.

struct `primitive_desc` : public `dnnl::primitive_desc`

Primitive descriptor for an inner product backward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, const *memory::desc* &diff_src_desc, const *memory::desc* &weights_desc, const *memory::desc* &diff_dst_desc, const *inner_product_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an inner product backward propagation primitive.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **diff_src_desc** – Memory descriptor for diff src.
- **weights_desc** – Memory descriptor for weights.
- **diff_dst_desc** – Memory descriptor for diff dst.
- **hint_fwd_pd** – Primitive descriptor for an inner product forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **diff_src_desc**() const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **weights_desc**() const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **diff_dst_desc**() const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

prop_kind **get_prop_kind**() const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

struct *dnnl::inner_product_backward_weights* : public *dnnl::primitive*

Inner product weights gradient primitive.

Public Functions

inner_product_backward_weights()

Default constructor. Produces an empty object.

inner_product_backward_weights(const *primitive_desc* &pd)

Constructs an inner product weights gradient primitive.

Parameters **pd** – Primitive descriptor for an inner product weights gradient primitive.

struct **primitive_desc** : public dnnl::*primitive_desc*

Primitive descriptor for an inner product weights gradient primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_desc, const *inner_product_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an inner product weights update primitive with bias.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **src_desc** – Memory descriptor for src.
- **diff_weights_desc** – Memory descriptor for diff weights.
- **diff_bias_desc** – Memory descriptor for diff bias.
- **diff_dst_desc** – Memory descriptor for diff dst.
- **hint_fwd_pd** – Primitive descriptor for an inner product forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, const *memory::desc* &src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_dst_desc, const *inner_product_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an inner product weights update primitive.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **src_desc** – Memory descriptor for src.
- **diff_weights_desc** – Memory descriptor for diff weights.

- **diff_dst_desc** – Memory descriptor for diff dst.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **hint_fwd_pd** – Primitive descriptor for an inner product forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc()** const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **diff_weights_desc()** const

Returns a diff weights memory descriptor.

Returns Diff weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff weights parameter.

memory::desc **diff_dst_desc()** const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

memory::desc **diff_bias_desc()** const

Returns the diff bias memory descriptor.

Returns The diff bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff bias parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

5.5.9 Layer normalization

The layer normalization primitive performs a forward or backward layer normalization operation on a 2-5D data tensor.

The layer normalization operation performs normalization over the last logical axis of the data tensor and is defined by the following formulas. We show formulas only for 3D data, which are straightforward to generalize to cases of higher dimensions. Variable names follow the standard *Conventions*.

Forward

$$\text{dst}(t, n, c) = \gamma(c) \cdot \frac{\text{src}(t, n, c) - \mu(t, n)}{\sqrt{\sigma^2(t, n) + \varepsilon}} + \beta(c),$$

where

- $\gamma(c), \beta(c)$ are optional scale and shift for a channel (see the *use_scale* and *use_shift* flag),
- $\mu(t, n), \sigma^2(t, n)$ are mean and variance (see *use_global_stats* flag), and
- ε is a constant to improve numerical stability.

Mean and variance are computed at runtime or provided by a user. When mean and variance are computed at runtime, the following formulas are used:

- $\mu(t, n) = \frac{1}{C} \sum_c \text{src}(t, n, c),$

$$\bullet \sigma^2(t, n) = \frac{1}{C} \sum_c (\text{src}(t, n, c) - \mu(t, n))^2.$$

The $\gamma(c)$ and $\beta(c)$ tensors are considered learnable.

Difference Between Forward Training and Forward Inference

If mean and variance are computed at runtime (i.e., `use_global_stats` is not set), they become outputs for the propagation kind `forward_training` (because they would be required during the backward propagation). Data layout for mean and variance must be specified during initialization of the layer normalization descriptor by passing the memory descriptor for statistics (e.g., by passing `stat_desc` in `dnnl::layer_normalization_forward::primitive_desc`). Mean and variance are not exposed for the propagation kind `forward_inference`.

Backward

The backward propagation computes `diff_src(t, n, c)`, `diff_γ(c)*`, and `diff_β(c)*` based on `diff_dst(t, n, c)`, `src(t, n, c)`, `μ(t, n)`, `σ2(t, n)`, `γ(c)*`, and `β(c)*`.

The tensors marked with an asterisk are used only when the primitive is configured to use $\gamma(c)$, and $\beta(c)$ (i.e. `use_scale` and `use_shift` is set).

Execution Arguments

Depending on the flags and propagation kind, the layer normalization primitive requires different inputs and outputs. For clarity, a summary is shown below.

	<code>forward_inference</code>	<code>forward_training</code>	<code>backward</code>	<code>backward_data</code>
<code>none</code>	<i>In:</i> src <i>Out:</i> dst	<i>In:</i> src <i>Out:</i> dst, μ, σ ²	<i>In:</i> diff_dst, src, μ, σ ² <i>Out:</i> diff_src	Same as for <code>backward</code>
<code>use_global_stats</code>	<i>In:</i> src, μ, σ ² <i>Out:</i> dst	<i>In:</i> src, μ, σ ² <i>Out:</i> dst	<i>In:</i> diff_dst, src, μ, σ ² <i>Out:</i> diff_src	Same as for <code>backward</code>
<code>use_scale</code>	<i>In:</i> src, γ <i>Out:</i> dst	<i>In:</i> src, γ <i>Out:</i> dst, μ, σ ²	<i>In:</i> diff_dst, src, μ, σ ² , γ <i>Out:</i> diff_src, diff_γ	Not supported
<code>use_shift</code>	<i>In:</i> src, β <i>Out:</i> dst	<i>In:</i> src, β <i>Out:</i> dst, μ, σ ²	<i>In:</i> diff_dst, src, μ, σ ² , β <i>Out:</i> diff_src, diff_β	Not supported
<code>use_scale use_shift</code>	<i>In:</i> src, γ, β <i>Out:</i> dst	<i>In:</i> src, γ, β <i>Out:</i> dst, μ, σ ²	<i>In:</i> diff_dst, src, μ, σ ² , γ, β <i>Out:</i> diff_src, diff_γ, diff_β	Not supported
<code>use_global_stats use_scale use_shift</code>	<i>In:</i> src, μ, σ ² , γ, β <i>Out:</i> dst	<i>In:</i> src, μ, σ ² , γ, β <i>Out:</i> dst	<i>In:</i> diff_dst, src, μ, σ ² , γ, β <i>Out:</i> diff_src, diff_γ, diff_β	Not supported

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_SRC</i>
γ, β	<i>DNNL_ARG_SCALE</i>
β	<i>DNNL_ARG_SHIFT</i>
mean (μ)	<i>DNNL_ARG_MEAN</i>
variance (σ)	<i>DNNL_ARG_VARIANCE</i>
dst	<i>DNNL_ARG_DST</i>
diff_dst	<i>DNNL_ARG_DIFF_DST</i>
diff_src	<i>DNNL_ARG_DIFF_SRC</i>
diff_ γ	<i>DNNL_ARG_DIFF_SCALE</i>
diff_ β	<i>DNNL_ARG_DIFF_SHIFT</i>

Operation Details

1. The different flavors of the primitive are partially controlled by the `flags` parameter that is passed to the primitive descriptor initialization function (e.g., `dnnl::layer_normalization_forward::primitive_desc`). Multiple flags can be combined using the bitwise OR operator (`|`).
2. For forward propagation, the mean and variance might be either computed at runtime (in which case they are outputs of the primitive) or provided by a user (in which case they are inputs). In the latter case, a user must set the `use_global_stats` flag. For the backward propagation, the mean and variance are always input parameters.
3. Both forward and backward propagation support in-place operations, meaning that `src` can be used as input and output for forward propagation, and `diff_dst` can be used as input and output for backward propagation. In case of an in-place operation, the original data will be overwritten. Note, however, that backward propagation requires original `src`, hence the corresponding forward propagation should not be performed in-place.

Data Types Support

The layer normalization supports the following combinations of data types.

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Propagation	Source / Destination	Mean / Variance / Scale / Shift
forward / backward	<i>f32</i>	<i>f32</i>
forward	<i>f16</i>	<i>f32</i>

Data Representation

Mean and Variance

The mean (μ) and variance (σ^2) are separate tensors with number of dimensions equal to $(data_ndims - 1)$ and size $(data_dim[0], data_dim[1], \dots, data_dim[ndims - 2])$.

The corresponding memory object can have an arbitrary memory format. Unless mean and variance are computed at runtime and not exposed (i.e., propagation kind is `forward_inference` and `use_global_stats` is not set), the user should provide a memory descriptor for statistics when initializing the layer normalization descriptor. For best performance, it is advised to use the memory format that follows the data memory format; i.e., if the data format is `tn`, the best performance can be expected for statistics with the `tn` format and suboptimal for statistics with the `nt` format.

Scale and Shift

If used, the scale (γ) and shift (β) are combined in a single 2D tensor of shape $2 \times C$.

The format of the corresponding memory object must be *nc (ab)*.

Source, Destination, and Their Gradients

The layer normalization primitive works with an arbitrary data tensor; however, it was designed for RNN data tensors (i.e., *nc*, *tnc*, *ldnc*). Unlike CNN data tensors, RNN data tensors have a single feature dimension. Layer normalization performs normalization over the last logical dimension (feature dimension for RNN tensors) across non-feature dimensions.

The layer normalization primitive is optimized for the following memory formats:

Logical tensor	Implementations optimized for memory formats
NC	<i>nc (ab)</i>
TNC	<i>tnc (abc)</i> , <i>ntc (bac)</i>
LDNC	<i>ldnc (abcd)</i>

API

```
struct dnnl::layer_normalization_forward : public dnnl::primitive
    Layer normalization forward propagation primitive.
```

Public Functions

layer_normalization_forward()
Default constructor. Produces an empty object.

layer_normalization_forward(const *primitive_desc* &pd)
Constructs a layer normalization forward propagation primitive.

Parameters **pd** – Primitive descriptor for a layer normalization forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
    Primitive descriptor for a layer normalization forward propagation primitive.
```

Public Functions

primitive_desc() = default
Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, const *memory::desc* &stat_desc, float epsilon, *normalization_flags* flags, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)
Constructs a primitive descriptor for a layer normalization forward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.

- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **stat_desc** – Statistics memory descriptors.
- **epsilon** – Layer normalization epsilon parameter.
- **flags** – Layer normalization flags (*dnnl::normalization_flags*).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, float epsilon, *normalization_flags* flags, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a layer normalization forward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **epsilon** – Layer normalization epsilon parameter.
- **flags** – Layer normalization flags (*dnnl::normalization_flags*).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

memory::desc **weights_desc**() const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **workspace_desc**() const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

memory::desc **mean_desc**() const

Returns memory descriptor for mean.

Returns Memory descriptor for mean.

memory::desc **variance_desc**() const

Returns memory descriptor for variance.

Returns Memory descriptor for variance.

dnnl::prop_kind **get_prop_kind**() const

Returns a propagation kind.

Returns A propagation kind.

Returns `dnnl::prop_kind::undef` if the primitive does not have a propagation parameter.

float **get_epsilon**() const

Returns an epsilon.

Returns An epsilon.

Returns Zero if the primitive does not have an epsilon parameter.

`normalization_flags` **get_flags**() const

Returns normalization flags.

Returns Normalization flags.

struct `dnnl::layer_normalization_backward` : public `dnnl::primitive`
Layer normalization backward propagation primitive.

Public Functions

layer_normalization_backward()

Default constructor. Produces an empty object.

layer_normalization_backward(const `primitive_desc` &pd)

Constructs a layer normalization backward propagation primitive.

Parameters `pd` – Primitive descriptor for a layer normalization backward propagation primitive.

struct **primitive_desc** : public `dnnl::primitive_desc`

Primitive descriptor for a layer normalization backward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const `engine` &aengine, `prop_kind` aprop_kind, const `memory::desc` &diff_src_desc, const `memory::desc` &diff_dst_desc, const `memory::desc` &src_desc, const `memory::desc` &stat_desc, float epsilon, `normalization_flags` flags, const `layer_normalization_forward::primitive_desc` &hint_fwd_pd, const `primitive_attr` &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a layer normalization backward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::backward_data` and `dnnl::prop_kind::backward` (diffs for all parameters are computed in this case).
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **src_desc** – Source memory descriptor.
- **stat_desc** – Statistics memory descriptors.
- **epsilon** – Layer normalization epsilon parameter.
- **flags** – Layer normalization flags (`dnnl::normalization_flags`).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **hint_fwd_pd** – Primitive descriptor for a layer normalization forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_dst_desc, const *memory::desc* &src_desc, float epsilon, *normalization_flags* flags, const *layer_normalization_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a layer normalization backward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::backward_data* and *dnnl::prop_kind::backward* (diffs for all parameters are computed in this case).
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **src_desc** – Source memory descriptor.
- **epsilon** – Layer normalization epsilon parameter.
- **flags** – Layer normalization flags (*dnnl::normalization_flags*).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **hint_fwd_pd** – Primitive descriptor for a layer normalization forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **weights_desc**() const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

memory::desc **diff_src_desc**() const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **diff_dst_desc**() const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

memory::desc **diff_weights_desc**() const

Returns a diff weights memory descriptor.

Returns Diff weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff weights parameter.

memory::desc **mean_desc**() const

Returns memory descriptor for mean.

Returns Memory descriptor for mean.

memory::desc **variance_desc**() const

Returns memory descriptor for variance.

Returns Memory descriptor for variance.

memory::desc **workspace_desc()** const
Returns the workspace memory descriptor.
Returns Workspace memory descriptor.
Returns A zero memory descriptor if the primitive does not require workspace parameter.

dnnl::prop_kind **get_prop_kind()** const
Returns a propagation kind.
Returns A propagation kind.
Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

float **get_epsilon()** const
Returns an epsilon.
Returns An epsilon.
Returns Zero if the primitive does not have an epsilon parameter.

normalization_flags **get_flags()** const
Returns normalization flags.
Returns Normalization flags.

5.5.10 Local Response Normalization

The LRN primitive performs a forward or backward local response normalization operation defined by the following formulas. Variable names follow the standard *Conventions*.

Forward

LRN with algorithm *lrn_across_channels*:

$$\text{dst}(n, c, h, w) = \left\{ k + \frac{\alpha}{n_l} \sum_{i=-(n_l-1)/2}^{(n_l+1)/2-1} (\text{src}(n, c + i, h, w))^2 \right\}^{-\beta} \cdot \text{src}(n, c, h, w),$$

LRN with algorithm *lrn_within_channel*:

$$\text{dst}(n, c, h, w) = \left\{ k + \frac{\alpha}{n_l} \sum_{i=-(n_l-1)/2}^{(n_l+1)/2-1} \sum_{j=-(n_l-1)/2}^{(n_l+1)/2-1} (\text{src}(n, c, h + i, w + j))^2 \right\}^{-\beta} \cdot \text{src}(n, c, h, w),$$

where n_l is the `local_size`. Formulas are provided for 2D spatial data case.

Backward

The backward propagation computes $\text{diff_src}(n, c, h, w)$, based on $\text{diff_dst}(n, c, h, w)$ and $\text{src}(n, c, h, w)$.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_SRC</i>
dst	<i>DNNL_ARG_DST</i>
workspace	<i>DNNL_ARG_WORKSPACE</i>
diff_src	<i>DNNL_ARG_DIFF_SRC</i>
diff_dst	<i>DNNL_ARG_DIFF_DST</i>

Operation Details

1. During training, LRN might or might not require a workspace on forward and backward passes. The behavior is implementation specific. Optimized implementations typically require a workspace and use it to save some intermediate results from the forward pass that accelerate computations on the backward pass. To check whether a workspace is required, query the LRN primitive descriptor for the workspace. Success indicates that the workspace is required and its description will be returned.

Data Type Support

The LRN primitive supports the following combinations of data types.

Note: Here we abbreviate data types names for readability. For example, *dnnl::memory::data_type::f32* is abbreviated to *f32*.

Propagation	Source / Destination
forward / backward	<i>f32, bf16</i>
forward	<i>f16</i>

Data Representation

Source, Destination, and Their Gradients

Like most other primitives, the LRN primitive expects the following tensors:

Spatial	Source / Destination
0D	$N \times C$
1D	$N \times C \times W$
2D	$N \times C \times H \times W$
3D	$N \times C \times D \times H \times W$

The LRN primitive is optimized for the following memory formats:

Spatial	Logical tensor	Implementations optimized for memory formats
2D	NCHW	<i>nchw (abcd), nhwc (acdb), optimized</i>

Here *optimized* means the format chosen by the preceding compute-intensive primitive.

Post-ops and Attributes

The LRN primitive does not support any post-ops or attributes.

API

```
struct dnnl::lrn_forward : public dnnl::primitive
    Local response normalization (LRN) forward propagation primitive.
```

Public Functions

lrn_forward()

Default constructor. Produces an empty object.

lrn_forward(const *primitive_desc* &pd)

Constructs an LRN forward propagation primitive.

Parameters **pd** – Primitive descriptor for an LRN forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
```

Primitive descriptor for an LRN forward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, *memory::dim* local_size, float alpha, float beta, float k, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an LRN forward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – LRN algorithm kind: either *dnnl::algorithm::lrn_across_channels*, or *dnnl::algorithm::lrn_within_channel*.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **local_size** – Regularization local size.
- **alpha** – The alpha regularization parameter.
- **beta** – The beta regularization parameter.
- **k** – The k regularization parameter.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc()** const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

algorithm **get_algorithm()** const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

float **get_alpha()** const

Returns an alpha.

Returns An alpha.

Returns Zero if the primitive does not have an alpha parameter.

float **get_beta()** const

Returns a beta.

Returns A beta.

Returns Zero if the primitive does not have a beta parameter.

memory::dim **get_local_size()** const

Returns an LRN local size parameter.

Returns An LRN local size parameter.

Returns Zero if the primitive does not have an LRN local size parameter.

float **get_k()** const

Returns an LRN K parameter.

Returns An LRN K parameter.

Returns Zero if the primitive does not have an LRN K parameter.

struct **dnnl::lrn_backward** : public *dnnl::primitive*

Local response normalization (LRN) backward propagation primitive.

Public Functions

lrn_backward()

Default constructor. Produces an empty object.

lrn_backward(const *primitive_desc* &pd)

Constructs an LRN backward propagation primitive.

Parameters **pd** – Primitive descriptor for an LRN backward propagation primitive.

struct **primitive_desc** : public *dnnl::primitive_desc*

Primitive descriptor for an LRN backward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_dst_desc, const *memory::desc* &src_desc, *memory::dim* local_size, float alpha, float beta, float k, const *lrn_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an LRN backward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – LRN algorithm kind: either *dnnl::algorithm::lrn_across_channels*, or *dnnl::algorithm::lrn_within_channel*.
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **src_desc** – Source memory descriptor.
- **local_size** – Regularization local size.
- **alpha** – The alpha regularization parameter.
- **beta** – The beta regularization parameter.
- **k** – The k regularization parameter.
- **hint_fwd_pd** – Primitive descriptor for an LRN forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **diff_src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **diff_dst_desc**() const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

memory::desc **workspace_desc**() const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

algorithm **get_algorithm**() const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind**() const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

float **get_alpha**() const

Returns an alpha.

Returns An alpha.

Returns Zero if the primitive does not have an alpha parameter.

float **get_beta**() const

Returns a beta.

Returns A beta.

Returns Zero if the primitive does not have a beta parameter.

memory::dim **get_local_size**() const

Returns an LRN local size parameter.

Returns An LRN local size parameter.

Returns Zero if the primitive does not have an LRN local size parameter.

float **get_k**() const

Returns an LRN K parameter.

Returns An LRN K parameter.

Returns Zero if the primitive does not have an LRN K parameter.

5.5.11 Matrix Multiplication

The matrix multiplication (MatMul) primitive computes the product of two 2D tensors with optional bias addition. Variable names follow the standard *Conventions*.

$$\text{dst}(m, n) = \sum_{k=0}^{K-1} (\text{src}(m, k) \cdot \text{weights}(k, n)) + \text{bias}(m, n)$$

The MatMul primitive also supports batching multiple independent matrix multiplication operations, in which case the tensors must be 3D:

$$\text{dst}(mb, m, n) = \sum_{k=0}^{K-1} (\text{src}(mb, m, k) \cdot \text{weights}(mb, k, n)) + \text{bias}(mb, m, n)$$

The bias tensor is optional and supports implicit broadcast semantics: any of its dimensions can be 1 and the same value would be used across the corresponding dimension. However, bias must have the same number of dimensions as the dst.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_SRC</i>
weights	<i>DNNL_ARG_WEIGHTS</i>
bias	<i>DNNL_ARG_BIAS</i>
dst	<i>DNNL_ARG_DST</i>

Operation Details

The MatMul primitive supports input and output tensors with run-time specified shapes and memory formats. The run-time specified dimensions or strides are specified using the `DNNL_RUNTIME_DIM_VAL` wildcard value during the primitive initialization and creation stage. At the execution stage, the user must pass fully specified memory objects so that the primitive is able to perform the computations. Note that the less information about shapes or format is available at the creation stage, the less performant execution will be. In particular, if the shape is not known at creation stage, one cannot use the special format tag `any` to enable an implementation to choose the most appropriate memory format for the corresponding input or output shapes. On the other hand, run-time specified shapes enable users to create a primitive once and use it in different situations.

Data Types Support

The MatMul primitive supports the following combinations of data types for source, destination, weights, and bias tensors.

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Source	Weights	Destination	Bias
<code>f32</code>	<code>f32</code>	<code>f32</code>	<code>f32</code>
<code>f16</code>	<code>f16</code>	<code>f16</code>	<code>f16</code>
<code>bf16</code>	<code>bf16</code>	<code>bf16</code>	<code>bf16, f32</code>
<code>u8, s8</code>	<code>s8, u8</code>	<code>u8, s8, s32, f32</code>	<code>u8, s8, s32, f32</code>

Data Representation

The MatMul primitive expects the following tensors:

Dims	Source	Weights	Destination	Bias (optional)
2D	$M \times K$	$K \times N$	$M \times N$	$(M \text{ or } 1) \times (N \text{ or } 1)$
3D	$MB \times M \times K$	$MB \times K \times N$	$MB \times M \times N$	$(MB \text{ or } 1) \times (M \text{ or } 1) \times (N \text{ or } 1)$

The MatMul primitive is generally optimized for the case in which memory objects use plain memory formats (with some restrictions; see the table below). However, it is recommended to use the placeholder memory format `any` if an input tensor is reused across multiple executions. In this case, the primitive will set the most appropriate memory format for the corresponding input tensor.

The table below shows the combinations of memory formats for which the MatMul primitive is optimized. The memory format of the destination tensor should always be `ab` for the 2D case and `abc` for the 3D one.

Dims	Logical tensors	MatMul is optimized for the following memory formats
2D	Source: $M \times K$, Weights: $K \times N$	Source: <code>ab</code> or <code>ba</code> , Weights: <code>ab</code> or <code>ba</code>
3D	Source: $MB \times M \times K$, Weights: $MB \times K \times N$	Source: <code>abc</code> or <code>acb</code> , Weights: <code>abc</code> or <code>acb</code>

Attributes and Post-ops

Attributes and post-ops enable modifying the behavior of the MatMul primitive. The following attributes and post-ops are supported:

Type	Operation	Description	Restrictions
At-tribute	<i>Scales</i>	Sets scale(s) for the corresponding tensor(s)	
At-tribute	<i>Zero points</i>	Sets zero point(s) for the corresponding tensors	Int8 computations only
Post-op	<i>Eltwise</i>	Applies an elementwise operation to the result	
Post-op	<i>Binary</i>	Applies a binary operation to the result	
Post-op	<i>Sum</i>	Adds the operation result to the destination tensor instead of overwriting it	

The primitive supports dynamic quantization via run-time scales. That means a user could configure the scales and zero-point attributes at the primitive descriptor creation stage. The user must then provide the scales and zero-points as an additional input memory objects with argument *DNML_ARG_ATTR_SCALES* and *DNML_ARG_ATTR_ZERO_POINTS* during the execution stage (more details are provided in the *Quantization* section).

API

```
struct dnnl::matmul : public dnnl::primitive
    Matrix multiplication (matmul) primitive.
```

Public Functions

matmul()

Default constructor. Produces an empty object.

matmul(const *primitive_desc* &pd)

Constructs a matmul primitive.

Parameters **pd** – Primitive descriptor for a matmul primitive.

```
struct primitive_desc : public dnnl::primitive_desc
```

Primitive descriptor for a matmul primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &dst_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a matmul primitive without bias.

Parameters

- **aengine** – Engine to use.
- **src_desc** – Memory descriptor for source (matrix A).

- **weights_desc** – Memory descriptor for weights (matrix B).
- **dst_desc** – Memory descriptor for destination (matrix C).
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, const *memory::desc* &src_desc, const *memory::desc* &weights_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a matmul primitive with bias.

Parameters

- **aengine** – Engine to use.
- **src_desc** – Memory descriptor for source (matrix A).
- **weights_desc** – Memory descriptor for weights (matrix B).
- **dst_desc** – Memory descriptor for destination (matrix C).
- **bias_desc** – Memory descriptor for bias.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **weights_desc**() const

Returns a weights memory descriptor.

Returns Weights memory descriptor.

Returns A zero memory descriptor if the primitive does not have a weights parameter.

memory::desc **bias_desc**() const

Returns the bias memory descriptor.

Returns The bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

5.5.12 Pooling

The pooling primitive performs forward or backward max or average pooling operation on 1D, 2D, or 3D spatial data.

The pooling operation is defined by the following formulas. We show formulas only for 2D spatial data which are straightforward to generalize to cases of higher and lower dimensions. Variable names follow the standard *Conventions*.

Forward

Max pooling:

$$\text{dst}(n, c, oh, ow) = \max_{kh, kw} (\text{src}(n, c, oh \cdot SH + kh - PH_L, ow \cdot SW + kw - PW_L))$$

Average pooling:

$$\text{dst}(n, c, oh, ow) = \frac{1}{DENOM} \sum_{kh, kw} \text{src}(n, c, oh \cdot SH + kh - PH_L, ow \cdot SW + kw - PW_L)$$

Here output spatial dimensions are calculated similarly to how they are done for *Convolution and Deconvolution*.

Average pooling supports two algorithms:

- *pooling_avg_include_padding*, in which case $DENOM = KH \cdot KW$,
- *pooling_avg_exclude_padding*, in which case $DENOM$ equals to the size of overlap between an averaging window and images.

Difference Between Forward Training and Forward Inference

Max pooling requires a workspace for the *forward_training* propagation kind, and does not require it for *forward_inference* (see details below).

Backward

The backward propagation computes $\text{diff_src}(n, c, h, w)$, based on $\text{diff_dst}(n, c, h, w)$ and, in case of max pooling, workspace.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_SRC</i>
dst	<i>DNNL_ARG_DST</i>
workspace	<i>DNNL_ARG_WORKSPACE</i>
diff_src	<i>DNNL_ARG_DIFF_SRC</i>
diff_dst	<i>DNNL_ARG_DIFF_DST</i>

Operation Details

1. During training, max pooling requires a workspace on forward (*forward_training*) and backward passes to save indices where a maximum was found. The workspace format is opaque, and the indices cannot be restored from it. However, one can use backward pooling to perform up-sampling (used in some detection topologies). The workspace can be created via `dnnl::pooling_forward::primitive_desc::workspace_desc()`.
2. A user can use memory format tag *any* for dst memory descriptor when creating pooling forward propagation. The library would derive the appropriate format from the src memory descriptor. However, the src itself must be defined. Similarly, a user can use memory format tag *any* for the `diff_src` memory descriptor when creating pooling backward propagation.

Data Type Support

The pooling primitive supports the following combinations of data types.

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to *f32*.

Propagation	Source / Destination	Accumulation data type (used for average pooling only)
forward / backward	<i>f32</i> , <i>bf16</i>	<i>f32</i>
forward	<i>f16</i>	<i>f16</i>
forward	<i>s8</i> , <i>u8</i> , <i>s32</i>	<i>s32</i>

Data Representation

Source, Destination, and Their Gradients

Like other CNN primitives, the pooling primitive expects data to be an $N \times C \times W$ tensor for the 1D spatial case, an $N \times C \times H \times W$ tensor for the 2D spatial case, and an $N \times C \times D \times H \times W$ tensor for the 3D spatial case.

The pooling primitive is optimized for the following memory formats:

Spatial	Logical tensor	Data type	Implementations optimized for memory formats
1D	NCW	f32	<i>ncw (abc)</i> , <i>nwc (acb)</i> , <i>optimized^</i>
1D	NCW	s32, s8, u8	<i>nwc (acb)</i> , <i>optimized^</i>
2D	NCHW	f32	<i>nchw (abcd)</i> , <i>nhwc (acdb)</i> , <i>optimized^</i>
2D	NCHW	s32, s8, u8	<i>nhwc (acdb)</i> , <i>optimized^</i>
3D	NCDHW	f32	<i>ncdhw (abcde)</i> , <i>ndhwc (acdeb)</i> , <i>optimized^</i>
3D	NCDHW	s32, s8, u8	<i>ndhwc (acdeb)</i> , <i>optimized^</i>

Here *optimized^* means the format that comes out of any preceding compute-intensive primitive.

Post-ops and Attributes

The pooling primitive does not support any post-ops or attributes.

API

```
struct dnnl::pooling_forward : public dnnl::primitive
    Pooling forward propagation primitive.
```

Public Functions

pooling_forward()

Default constructor. Produces an empty object.

pooling_forward(const *primitive_desc* &pd)

Constructs a pooling forward propagation primitive.

Parameters **pd** – Primitive descriptor for a pooling forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
    Primitive descriptor for a pooling forward propagation primitive.
```

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, const *memory::dims* &strides, const *memory::dims* &kernel, const *memory::dims* &dilation, const *memory::dims* &padding_l, const *memory::dims* &padding_r, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for pooling forward propagation primitive.

Arrays **strides**, **kernel**, **dilation**, **padding_l** and **padding_r** contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Parameters

- **aengine** – Engine to use.
- **prop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – Pooling algorithm kind: either *dnnl::algorithm::pooling_max*, *dnnl::algorithm::pooling_avg_include_padding*, or *dnnl::algorithm::pooling_avg_exclude_padding*.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **strides** – Vector of strides for spatial dimension.
- **kernel** – Vector of kernel spatial dimensions.
- **dilation** – Array of dilations for spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).

- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc()** const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc()** const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

algorithm **get_algorithm()** const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

memory::dims **get_strides()** const

Returns strides.

Returns Strides.

Returns An empty *dnnl::memory::dims* if the primitive does not have a strides parameter.

memory::dims **get_kernel()** const

Returns a pooling kernel parameter.

Returns A pooling kernel parameter.

Returns An empty *dnnl::memory::dims* if the primitive does not have a pooling kernel parameter.

memory::dims **get_dilations()** const

Returns dilations.

Returns Dilations.

Returns An empty *dnnl::memory::dims* if the primitive does not have a dilations parameter.

memory::dims **get_padding_l()** const

Returns a left padding.

Returns A left padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a left padding parameter.

memory::dims **get_padding_r()** const

Returns a right padding.

Returns A right padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a right padding parameter.

struct `dnnl::pooling_backward` : public `dnnl::primitive`
 Pooling backward propagation primitive.

Public Functions

`pooling_backward()`

Default constructor. Produces an empty object.

`pooling_backward(const primitive_desc &pd)`

Constructs a pooling backward propagation primitive.

Parameters `pd` – Primitive descriptor for a pooling backward propagation primitive.

struct `primitive_desc` : public `dnnl::primitive_desc`

Primitive descriptor for a pooling backward propagation primitive.

Public Functions

`primitive_desc() = default`

Default constructor. Produces an empty object.

`primitive_desc(const engine &aengine, algorithm aalgorithm, const memory::desc &diff_src_desc, const memory::desc &diff_dst_desc, const memory::dims &strides, const memory::dims &kernel, const memory::dims &dilation, const memory::dims &padding_l, const memory::dims &padding_r, const pooling_forward::primitive_desc &hint_fwd_pd, const primitive_attr &attr = default_attr(), bool allow_empty = false)`

Constructs a primitive descriptor for a pooling backward propagation primitive.

Arrays `strides`, `kernel`, `dilation`, `padding_l` and `padding_r` contain values for spatial dimensions only and hence must have the same number of elements as there are spatial dimensions. The order of values is the same as in the tensor: depth (for 3D tensors), height (for 3D and 2D tensors), and width.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Pooling algorithm kind: either `dnnl::algorithm::pooling_max`, `dnnl::algorithm::pooling_avg_include_padding`, or `dnnl::algorithm::pooling_avg_exclude_padding`.
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **strides** – Vector of strides for spatial dimension.
- **kernel** – Vector of kernel spatial dimensions.
- **dilation** – Array of dilations for spatial dimension.
- **padding_l** – Vector of padding values for low indices for each spatial dimension ([[front,] top,] left).
- **padding_r** – Vector of padding values for high indices for each spatial dimension ([[back,] bottom,] right).
- **hint_fwd_pd** – Primitive descriptor for a pooling forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc diff_src_desc()` const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **diff_dst_desc()** const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

algorithm **get_algorithm()** const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

memory::dims **get_strides()** const

Returns strides.

Returns Strides.

Returns An empty *dnnl::memory::dims* if the primitive does not have a strides parameter.

memory::dims **get_kernel()** const

Returns a pooling kernel parameter.

Returns A pooling kernel parameter.

Returns An empty *dnnl::memory::dims* if the primitive does not have a pooling kernel parameter.

memory::dims **get_dilations()** const

Returns dilations.

Returns Dilations.

Returns An empty *dnnl::memory::dims* if the primitive does not have a dilations parameter.

memory::dims **get_padding_l()** const

Returns a left padding.

Returns A left padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a left padding parameter.

memory::dims **get_padding_r()** const

Returns a right padding.

Returns A right padding.

Returns An empty *dnnl::memory::dims* if the primitive does not have a right padding parameter.

5.5.13 Prelu

The prelu primitive (Leaky ReLU with trainable alpha parameter) performs forward or backward operation on data tensor. Weights (alpha) tensor supports broadcast-semantics.

Broadcast configuration is assumed based on src and weights dimensions.

Forward

The prelu operation is defined by the following formulas. We show formulas only for 2D spatial data which are straightforward to generalize to cases of higher and lower dimensions. Variable names follow the standard *Conventions*.

$$\text{dst}(n, c, h, w) = \begin{cases} \text{src}(n, c, h, w) & \text{if } \text{src}(n, c, h, w) > 0 \\ \text{src}(n, c, h, w) \cdot \text{weights}(n, c, h, w) & \text{if } \text{src}(n, c, h, w) \leq 0 \end{cases}$$

Difference Between Forward Training and Forward Inference

There is no difference between the *forward_training* and *forward_inference* propagation kinds.

Backward

The backward propagation computes diff_src and diff_weights. For no broadcast case, results are calculated using formula:

$$\text{diff_src}(n, c, h, w) = \begin{cases} \text{diff_dst}(n, c, h, w) & \text{if } \text{src}(n, c, h, w) > 0 \\ \text{diff_dst}(n, c, h, w) \cdot \text{weights}(n, c, h, w) & \text{if } \text{src}(n, c, h, w) \leq 0 \end{cases}$$

$$\text{diff_weights}(n, c, h, w) = \min(\text{src}(n, c, h, w), 0) \cdot \text{diff_dst}(n, c, h, w)$$

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_SRC</i>
dst	<i>DNNL_ARG_DST</i>
weights	<i>DNNL_ARG_WEIGHTS</i>
diff_src	<i>DNNL_ARG_DIFF_SRC</i>
diff_dst	<i>DNNL_ARG_DIFF_DST</i>
diff_weights	<i>DNNL_ARG_DIFF_WEIGHTS</i>

Operation Details

1. All input and output tensors must have the same number of dimensions.
2. weights tensor dimensions must follow broadcast semantics. Each dimension can either be equal to the corresponding data dimension or equal to 1 to indicate a broadcasted dimension.

Post-ops and Attributes

The prelu primitive does not have to support any post-ops or attributes.

Data Types Support

The PReLU primitive supports the following combinations of data types:

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Propagation	Source / Destination
forward / backward	<code>f32, s32, bf16, f16, s8, u8</code>

Data Representation

Source, Destination, and Their Gradients

The PReLU primitive works with arbitrary data tensors. There is no special meaning associated with any logical dimensions.

API

```
struct dnnl::prelu_forward : public dnnl::primitive
    PReLU forward propagation primitive.
```

Public Functions

prelu_forward() = default
Default constructor. Produces an empty object.

prelu_forward(const *primitive_desc* &pd)
Constructs a prelu forward propagation primitive.

Parameters **pd** – Primitive descriptor for a prelu forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
    Primitive descriptor for a PReLU forward propagation primitive.
```

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, const *memory::desc* &src_desc, const *memory::desc* &weight_desc, const *memory::desc* &dst_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a PReLU forward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **prop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **src_desc** – Source memory descriptor.
- **weight_desc** – Alpha parameters memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc()** const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc()** const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

struct **dnnl::prelu_backward** : public *dnnl::primitive*
PReLU backward propagation primitive.

Public Functions

prelu_backward() = default

Default constructor. Produces an empty object.

prelu_backward(const *primitive_desc* &pd)

Constructs a prelu backward propagation primitive.

Parameters **pd** – Primitive descriptor for a prelu backward propagation primitive.

struct **primitive_desc** : public *dnnl::primitive_desc*

Primitive descriptor for prelu backward propagation.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, const *memory::desc* &src_desc, const *memory::desc* &weight_desc, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_weights_desc, const *memory::desc* &diff_dst_desc, const *prelu_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a descriptor for a PReLU backward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **src_desc** – Source memory descriptor.
- **weight_desc** – Alpha parameters memory descriptor.
- **diff_src_desc** – Diff source memory descriptor.
- **diff_weights_desc** – Diff alpha parameters memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **hint_fwd_pd** – Primitive descriptor for a PReLU forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc()** const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **diff_src_desc()** const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **diff_dst_desc()** const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

5.5.14 Reduction

The reduction primitive performs a reduction operation on one or multiple arbitrary dimensions, with respect to a specified algorithm. Variable names follow the standard *Conventions*.

$$\text{dst}(f) = \underset{r \in R}{\text{reduce_op}} \text{src}(r),$$

where *reduce_op* can be max, min, sum, mul, mean, Lp-norm and Lp-norm-power-p, *f* is an index in an idle dimension and *r* is an index in a reduction dimension *R*.

The reduction algorithms are specified as follow.

Mean:

$$\text{dst}(f) = \frac{\sum_{r \in R} \text{src}(r)}{\|R\|},$$

where $|R|$ is the size of a reduction dimension.

Lp-norm:

$$\text{dst}(f) = \sqrt[p]{\text{eps_op}\left(\sum_{r \in R} |\text{src}(r)|^p, \text{eps}\right)},$$

where *eps_op* can be max and sum.

Lp-norm-power-p:

$$\text{dst}(f) = \text{eps_op}\left(\sum_r |\text{src}(r)|^p, \text{eps}\right),$$

where *eps_op* can be max and sum.

Note:

- The reduction primitive requires the source and destination tensors to have the same number of dimensions.
 - Dimensions which are reduced are of size 1 in the destination tensor.
 - The reduction primitive does not have a notion of forward or backward propagations.
-

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_SRC</i>
dst	<i>DNNL_ARG_DST</i>

Operation Details

The dst memory format can be either specified explicitly or by using the special format tag *any* (recommended), in which case the primitive will derive the most appropriate memory format based on the format of the source tensor.

Data Types Support

The reduction primitive supports the following combinations of data types:

Propagation	Source / Destination
forward / backward	<i>f32, s32, bf16, f16, s8, u8</i>

Data Representation

The reduction primitive works with arbitrary data tensors. There is no special meaning associated with any of the dimensions of a tensor.

Attributes and Post-ops

Type	Operation	Description	Restrictions
Attribute	<i>Scales</i>	Sets scale(s) for the corresponding tensor(s)	Int8 computations only
Attribute	<i>Zero points</i>	Sets zero point(s) for the corresponding tensors	Int8 computations only
post-op	<i>Eltwise</i>	Applies an elementwise operation to the result	
post-op	<i>Binary</i>	Applies a binary operation to the result	

API

```
struct dnnl::reduction : public dnnl::primitive
    Reduction.
```

Public Functions

reduction() = default
Default constructor. Produces an empty object.

```
struct primitive_desc : public dnnl::primitive_desc
    Primitive descriptor for a reduction primitive.
```

Public Functions

primitive_desc() = default
Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, float p, float eps, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a reduction primitive using algorithm specific parameters, source and destination memory descriptors.

Note: Destination memory descriptor may be initialized with *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – reduction algorithm kind. Possible values: *algorithm::reduction_max*, *algorithm::reduction_min*, *algorithm::reduction_sum*, *algorithm::reduction_mul*, *algorithm::reduction_mean*, *algorithm::reduction_norm_lp_max*, *algorithm::reduction_norm_lp_sum*, *algorithm::reduction_norm_lp_power_p_max*, *algorithm::reduction_norm_lp_power_p_sum*.
- **p** – algorithm specific parameter.
- **eps** – algorithm specific parameter.

- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

float **get_p**() const

Returns a reduction P parameter.

Returns A reduction P parameter.

Returns Zero if the primitive does not have a reduction P parameter.

float **get_epsilon**() const

Returns an epsilon.

Returns An epsilon.

Returns Zero if the primitive does not have an epsilon parameter.

algorithm **get_algorithm**() const

Returns an algorithm kind.

Returns An algorithm kind.

Returns *dnnl::algorithm::undef* if the primitive does not have an algorithm parameter.

5.5.15 Reorder

A primitive to copy data between two memory objects. This primitive is typically used to change the way that the data is laid out in memory.

The reorder primitive copies data between different memory formats but does not change the tensor from mathematical perspective. Variable names follow the standard *Conventions*.

$$\text{dst}(\bar{x}) = \text{src}(\bar{x})$$

for $\bar{x} = (x_0, \dots, x_n)$.

As described in *Introduction* in order to achieve the best performance some primitives (such as convolution) require special memory format which is typically referred to as an *optimized* memory format. The *optimized* memory format may match or may not match memory format that data is currently kept in. In this case a user can use reorder primitive to copy (reorder) the data between the memory formats.

Using the attributes and post-ops users can also use reorder primitive to quantize the data (and if necessary change the memory format simultaneously).

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_FROM</i>
dst	<i>DNNL_ARG_TO</i>

Operation Details

1. The reorder primitive requires the source and destination tensors to have the same shape. Implicit broadcasting is not supported.
2. While in most of the cases the reorder should be able to handle arbitrary source and destination memory formats and data types, it might happen that some combinations are not implemented. For instance:
 - Reorder implementations between weights in non-plain memory formats might be limited (but if encountered in real practice should be treated as a bug and reported to oneDNN team);
 - Weights in one Winograd format cannot be reordered to the weights of the other Winograd format;
 - Quantized weights for convolution with #dnnl_s8 source data type cannot be dequantized back to the #dnnl_f32 data type;
3. To alleviate the problem a user may rely on fact that the reorder from original plain memory format and user's data type to the *optimized* format with chosen data type should be always implemented.

Data Types Support

The reorder primitive supports arbitrary data types for the source and destination.

When converting the data from one data type to a smaller one saturation is used. For instance:

```
reorder(src={1024, data_type=f32}, dst={}, data_type=s8)
// dst == {127}

reorder(src={-124, data_type=f32}, dst={}, data_type=u8)
// dst == {0}
```

Data Representation

The reorder primitive works with arbitrary data tensors. There is no special meaning associated with any logical dimensions.

Post-ops and Attributes

The reorder primitive should support the following attributes and post-ops:

Type	Operation	Description	Restrictions
At-tribute	<i>Scales</i>	Sets scale(s) for the corresponding tensor(s)	Int8 computations only
At-tribute	<i>Zero points</i>	Sets zero point(s) for the corresponding tensors	Int8 computations only
post-op	<i>Sum</i>	Adds the operation result to the destination tensor instead of overwriting it	

For instance, the following pseudo-code

```
reorder(
  src = {dims={N, C, H, W}, data_type=dt_src, memory_format=fmt_src},
  dst = {dims={N, C, H, W}, data_type=dt_dst, memory_format=fmt_dst},
  attr = {
    output_scale=alpha,
    post_ops = { sum={scale=beta} },
  })
```

would lead to the following operation:

$$\text{dst}(\bar{x}) = \alpha \cdot \text{src}(\bar{x}) + \beta \cdot \text{dst}(\bar{x})$$

Note: The intermediate operations are being done using single precision floating point data type.

API

```
struct dnnl::reorder : public dnnl::primitive
  Reorder primitive.
```

Public Functions

reorder()

Default constructor. Produces an empty object.

reorder(const *primitive_desc* &pd)

Constructs a reorder primitive.

Parameters **pd** – Primitive descriptor for reorder primitive.

reorder(const *memory* &src, const *memory* &dst, const *primitive_attr* &attr = *primitive_attr*())

Constructs a reorder primitive that would reorder data between memory objects having the same memory descriptors as memory objects **src** and **dst**.

Parameters

- **src** – Source memory object.
- **dst** – Destination memory object.

- **attr** – Primitive attributes to use (optional).

void **execute**(const *stream* &astream, *memory* &src, *memory* &dst) const
Executes the reorder primitive.

Parameters

- **astream** – Stream object. The stream must belong to the same engine as the primitive.
- **src** – Source memory object.
- **dst** – Destination memory object.

struct **primitive_desc** : public dnnl::*primitive_desc_base*
Primitive descriptor for a reorder primitive.

Public Functions

primitive_desc()

Default constructor. Produces an empty object.

primitive_desc(const *engine* &src_engine, const *memory::desc* &src_md, const *engine* &dst_engine,
const *memory::desc* &dst_md, const *primitive_attr* &attr = *primitive_attr*(), bool
allow_empty = false)

Constructs a primitive descriptor for reorder primitive.

Note: If `allow_empty` is true, the constructor does not throw if a primitive descriptor cannot be created.

Parameters

- **src_engine** – Engine on which the source memory object will be located.
- **src_md** – Source memory descriptor.
- **dst_engine** – Engine on which the destination memory object will be located.
- **dst_md** – Destination memory descriptor.
- **attr** – Primitive attributes to use (optional).
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *memory* &src, const *memory* &dst, const *primitive_attr* &attr = *primitive_attr*(),
bool allow_empty = false)

Constructs a primitive descriptor for reorder primitive.

Parameters

- **src** – Source memory object. It is used to obtain the source memory descriptor and engine.
- **dst** – Destination memory object. It is used to obtain the destination memory descriptor and engine.
- **attr** – Primitive attributes to use (optional).
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

engine **get_src_engine**() const

Returns the engine on which the source memory is allocated.

Returns The engine on which the source memory is allocated.

engine **get_dst_engine()** const

Returns the engine on which the destination memory is allocated.

Returns The engine on which the destination memory is allocated.

memory::desc **src_desc()** const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc()** const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

5.5.16 Resampling

The resampling primitive computes forward or backward resampling operation on 1D, 2D, or 3D spatial data. Resampling performs spatial scaling of original tensor using one of the supported interpolation algorithms:

- Nearest Neighbor
- Linear (or Bilinear for 2D spatial tensor, Trilinear for 3D spatial tensor).

Resampling operation is defined by the source tensor and scaling factors in each spatial dimension. Upsampling and downsampling are the alternative terms for resampling that are used when all scaling factors are greater (upsampling) or less (downsampling) than one.

The resampling operation is defined by the following formulas. We show formulas only for 2D spatial data which are straightforward to generalize to cases of higher and lower dimensions. Variable names follow the standard *Conventions*.

Let src and dst be $N \times C \times IH \times IW$ and $N \times C \times OH \times OW$ tensors respectively. Let $F_h = \frac{OH}{IH}$ and $F_w = \frac{OW}{IW}$ define scaling factors in each spatial dimension.

The following formulas show how oneDNN computes resampling for nearest neighbor and bilinear interpolation methods. To further simplify the formulas, we assume the following:

- $\text{src}(n, ic, ih, iw) = 0$ if $ih < 0$ or $iw < 0$,
- $\text{src}(n, ic, ih, iw) = \text{src}(n, ic, IH - 1, iw)$ if $ih \geq IH$,
- $\text{src}(n, ic, ih, iw) = \text{src}(n, ic, ih, IW - 1)$ if $iw \geq IW$.

Forward

Nearest Neighbor Resampling

$$\text{dst}(n, c, oh, ow) = \text{src}(n, c, ih, iw)$$

where

- $ih = \left[\frac{oh+0.5}{F_h} - 0.5 \right]$,
- $iw = \left[\frac{ow+0.5}{F_w} - 0.5 \right]$.

Bilinear Resampling

$$\begin{aligned} \text{dst}(n, c, oh, ow) = & \text{src}(n, c, ih_0, iw_0) \cdot W_{ih} \cdot W_{iw} + \\ & \text{src}(n, c, ih_1, iw_0) \cdot (1 - W_{ih}) \cdot W_{iw} + \\ & \text{src}(n, c, ih_0, iw_1) \cdot W_{ih} \cdot (1 - W_{iw}) + \\ & \text{src}(n, c, ih_1, iw_1) \cdot (1 - W_{ih}) \cdot (1 - W_{iw}) \end{aligned}$$

where

- $ih_0 = \left\lfloor \frac{oh+0.5}{F_h} - 0.5 \right\rfloor$,
- $ih_1 = \left\lceil \frac{oh+0.5}{F_h} - 0.5 \right\rceil$,
- $iw_0 = \left\lfloor \frac{ow+0.5}{F_w} - 0.5 \right\rfloor$,
- $iw_1 = \left\lceil \frac{ow+0.5}{F_w} - 0.5 \right\rceil$,
- $W_{ih} = \frac{oh+0.5}{F_h} - 0.5 - ih_0$,
- $W_{iw} = \frac{ow+0.5}{F_w} - 0.5 - iw_0$.

Difference Between Forward Training and Forward Inference

There is no difference between the *forward_training* and *forward_inference* propagation kinds.

Backward

The backward propagation computes *diff_src* based on *diff_dst*.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
<i>src</i>	<i>DNNL_ARG_SRC</i>
<i>dst</i>	<i>DNNL_ARG_DST</i>
<i>diff_src</i>	<i>DNNL_ARG_DIFF_SRC</i>
<i>diff_dst</i>	<i>DNNL_ARG_DIFF_DST</i>

Operation Details

1. Resampling implementation supports data with arbitrary data tag (*nchw*, *nhwc*, etc.) but memory tags for *src* and *dst* are expected to be the same. Resampling primitive supports *dst* and *diff_src* memory tag *any* and can define destination format based on source format.
2. Resampling descriptor can be created by specifying the source and destination memory descriptors, only the source descriptor and floating point factors, or the source and destination memory descriptors and factors. In case when user does not provide the destination descriptor, the destination dimensions are deduced using the factors: $output_spatial_size = \left\lfloor \frac{input_spatial_size}{F} \right\rfloor$.

Note: Resampling algorithm uses factors as defined by the relation $F = \frac{output_spatial_size}{input_spatial_size}$ that do not necessarily equal to the ones passed by the user.

Data Types Support

Resampling primitive supports the following combination of data types for source and destination memory objects.

Note: Here we abbreviate data types names for readability. For example, *dnnl::memory::data_type::f32* is abbreviated to *f32*.

Propagation	Source / Destination
forward / backward	<i>f32, bf16</i>
forward	<i>f16, s8, u8</i>

Post-ops and Attributes

The resampling primitive does not support any post-ops or attributes.

API

```
struct dnnl::resampling_forward : public dnnl::primitive
    Resampling forward propagation.
```

Public Functions

resampling_forward()

Default constructor. Produces an empty object.

resampling_forward(const *primitive_desc* &pd)

Constructs a resampling forward propagation primitive.

Parameters **pd** – Primitive descriptor for a resampling forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
```

Primitive descriptor for a resampling forward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a resampling forward propagation primitive using source and destination memory descriptors.

Note: Destination memory descriptor may be initialized with *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – resampling algorithm kind: either *dnnl::algorithm::resampling_nearest*, or *dnnl::algorithm::resampling_linear*
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const std::vector<float> &factors, const *memory::desc* &src_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a resampling forward propagation primitive using source memory descriptor and factors.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – resampling algorithm kind: either *dnnl::algorithm::resampling_nearest*, or *dnnl::algorithm::resampling_linear*
- **factors** – Vector of scaling factors for spatial dimension.
- **src_desc** – Source memory descriptor.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* aalgorithm, const std::vector<float> &factors, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a resampling forward propagation primitive.

Note: The destination memory descriptor may be initialized with *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **aalgorithm** – resampling algorithm kind: either *dnnl::algorithm::resampling_nearest*, or *dnnl::algorithm::resampling_linear*
- **factors** – Vector of scaling factors for spatial dimension.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc**() const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

struct **dnnl::resampling_backward** : public *dnnl::primitive*
Resampling backward propagation primitive.

Public Functions

resampling_backward()

Default constructor. Produces an empty object.

resampling_backward(const *primitive_desc* &pd)

Constructs a resampling backward propagation primitive.

Parameters **pd** – Primitive descriptor for a resampling backward propagation primitive.

struct **primitive_desc** : public *dnnl::primitive_desc*
Primitive descriptor for resampling backward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_dst_desc, const *resampling_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a resampling backward propagation primitive using source and destination memory descriptors.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – resampling algorithm kind: either *dnnl::algorithm::resampling_nearest*, or *dnnl::algorithm::resampling_linear*
- **diff_src_desc** – Diff source memory descriptor.

- **diff_dst_desc** – Diff destination memory descriptor.
- **hint_fwd_pd** – Primitive descriptor for a resampling forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *algorithm* aalgorithm, const std::vector<float> &factors, const *memory::desc* &diff_src_desc, const *memory::desc* &diff_dst_desc, const *resampling_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for resampling backward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – resampling algorithm kind: either *dnnl::algorithm::resampling_nearest*, or *dnnl::algorithm::resampling_linear*
- **factors** – Vector of scaling factors for spatial dimension.
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **hint_fwd_pd** – Primitive descriptor for a resampling forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **diff_src_desc**() const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

memory::desc **diff_dst_desc**() const

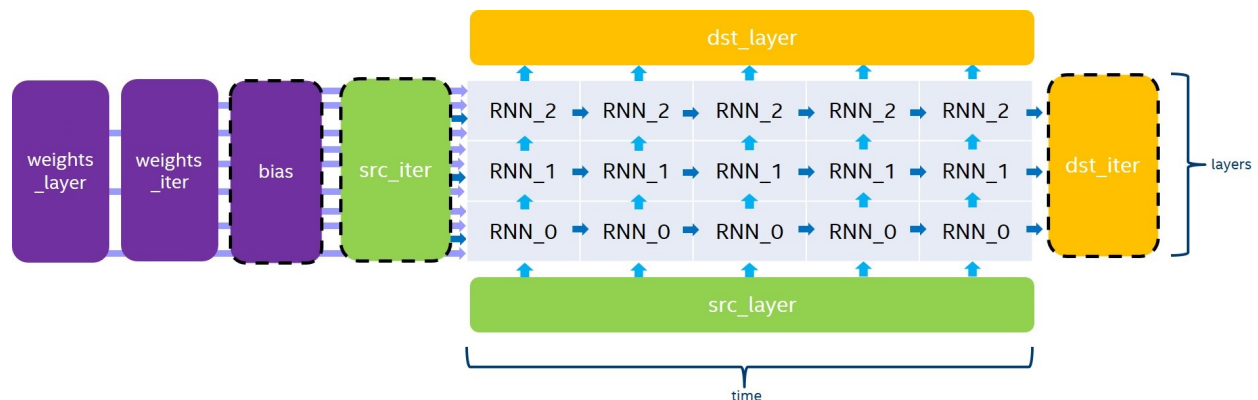

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

5.5.17 RNN

The RNN primitive computes a stack of unrolled recurrent cells, as depicted in Figure 1. *bias*, *src_iter* and *dst_iter* are optional parameters. If not provided, *bias* and *src_iter* default to 0. Variable names follow the standard *Conventions*.

The RNN primitive supports four modes for evaluation direction:

- `left2right` will process the input data timestamps by increasing order,
- `right2left` will process the input data timestamps by decreasing order,
- `bidirectional_concat` will process all the stacked layers from `left2right` and from `right2left` independently, and will concatenate the output in `dst_layer` over the channel dimension,
- `bidirectional_sum` will process all the stacked layers from `left2right` and from `right2left` independently, and will sum the two outputs to `dst_layer`.

Even though the RNN primitive supports passing a different number of channels for `src_layer`, `src_iter`, `dst_layer`, and `dst_iter`, we always require the following conditions in order for the dimension to be consistent:

- $channels(dst_layer) = channels(dst_iter)$,
- when $T > 1$, $channels(src_iter) = channels(dst_iter)$,
- when $L > 1$, $channels(src_layer) = channels(dst_layer)$,
- when using the `bidirectional_concat` direction, $channels(dst_layer) = 2 * channels(dst_iter)$.

The general formula for the execution of a stack of unrolled recurrent cells depends on the current iteration of the previous layer ($h_{t,l-1}$ and $c_{t,l-1}$) and the previous iteration of the current layer ($h_{t-1,l}$). Here is the exact equation for non-LSTM cells:

$$h_{t,l} = Cell(h_{t,l-1}, h_{t-1,l})$$

where t, l are the indices of the timestamp and the layer of the cell being executed.

And here is the equation for LSTM cells:

$$(h_{t,l}, c_{t,l}) = Cell(h_{t,l-1}, h_{t-1,l}, c_{t-1,l})$$

where t, l are the indices of the timestamp and the layer of the cell being executed.

Cell Functions

The RNN API provides six cell functions:

- *Vanilla RNN*, a single-gate recurrent cell,
- *LSTM*, a four-gate long short-term memory cell,
- *GRU*, a three-gate gated recurrent unit cell,
- *Linear-before-reset GRU*, a three-gate recurrent unit cell with the linear layer before the reset gate.
- *AUGRU*, a three-gate gated recurrent unit cell with the attention update gate,
- *Linear-before-reset AUGRU*, a three-gate recurrent unit cell with the linear layer before the reset gate and the attention update gate.

Vanilla RNN

A single-gate recurrent cell initialized with `dnnl::vanilla_rnn_forward::primitive_desc` or `dnnl::vanilla_rnn_backward::primitive_desc` as in the following example.

```
auto vanilla_rnn_pd =
    dnnl::vanilla_rnn_forward::primitive_desc(engine, aprop,
        activation, direction, src_layer_desc, src_iter_desc,
        weights_layer_desc, weights_iter_desc, bias_desc,
        dst_layer_desc, dst_iter_desc, attr);
```

The Vanilla RNN cell should support the ReLU, Tanh and Sigmoid activation functions. The following equations defines the mathematical operation performed by the Vanilla RNN cell for the forward pass:

$$a_t = W \cdot h_{t,l-1} + U \cdot h_{t-1,l} + B$$

$$h_t = \text{activation}(a_t)$$

LSTM

LSTM (or Vanilla LSTM)

A four-gate long short-term memory recurrent cell initialized with `dnnl::lstm_forward::primitive_desc` or `dnnl::lstm_backward::primitive_desc` as in the following example.

```
auto lstm_pd = dnnl::lstm_forward::primitive_desc(engine, aprop,
    direction, src_layer_desc, src_iter_h_desc, src_iter_c_desc,
    weights_layer_desc, weights_iter_desc, bias_desc,
    dst_layer_desc, dst_iter_h_desc, dst_iter_c_desc, attr);
```

Note that for all tensors with a dimension depending on the gates number, we implicitly require the order of these gates to be i , f , \tilde{c} , and o . The following equation gives the mathematical description of these gates and output for the forward pass:

$$i_t = \sigma(W_i \cdot h_{t,l-1} + U_i \cdot h_{t-1,l} + B_i)$$

$$f_t = \sigma(W_f \cdot h_{t,l-1} + U_f \cdot h_{t-1,l} + B_f)$$

$$\tilde{c}_t = \tanh(W_{\tilde{c}} \cdot h_{t,l-1} + U_{\tilde{c}} \cdot h_{t-1,l} + B_{\tilde{c}})$$

$$c_t = f_t * c_{t-1} + i_t * \tilde{c}_t$$

$$o_t = \sigma(W_o \cdot h_{t,l-1} + U_o \cdot h_{t-1,l} + B_o)$$

$$h_t = \tanh(c_t) * o_t$$

where W_* are stored in `weights_layer`, U_* are stored in `weights_iter` and B_* are stored in `bias`.

Note: In order for the dimensions to be consistent, we require `channels(src_iter_c) = channels(dst_iter_c) = channels(dst_iter)`.

LSTM with Peephole

A four-gate long short-term memory recurrent cell with peephole initialized with `dnnl::lstm_forward::primitive_desc` or `dnnl::lstm_backward::primitive_desc` as in the following example.

```
auto lstm_pd = dnnl::lstm_forward::primitive_desc(engine, aprop,
    direction, src_layer_desc, src_iter_h_desc, src_iter_c_desc,
    weights_layer_desc, weights_iter_desc, weights_peephole_desc,
    bias_desc, dst_layer_desc, dst_iter_h_desc, dst_iter_c_desc,
    attr);
```

Similarly to vanilla LSTM, we implicitly require the order of these gates to be i , f , \tilde{c} , and o . For peephole weights, the gates order is: i , f , o . The following equation gives the mathematical description of these gates and output for the forward pass:

$$\begin{aligned} i_t &= \sigma(W_i \cdot h_{t,l-1} + U_i \cdot h_{t-1,l} + P_i \cdot c_{t-1} + B_i) \\ f_t &= \sigma(W_f \cdot h_{t,l-1} + U_f \cdot h_{t-1,l} + P_f \cdot c_{t-1} + B_f) \\ \tilde{c}_t &= \tanh(W_{\tilde{c}} \cdot h_{t,l-1} + U_{\tilde{c}} \cdot h_{t-1,l} + B_{\tilde{c}}) \\ c_t &= f_t * c_{t-1} + i_t * \tilde{c}_t \\ o_t &= \sigma(W_o \cdot h_{t,l-1} + U_o \cdot h_{t-1,l} + P_o \cdot c_t + B_o) \\ h_t &= \tanh(c_t) * o_t \end{aligned}$$

where P_* are stored in `weights_peephole`, and the other parameters are the same as in vanilla LSTM.

Note: If the `weights_peephole_desc` passed to the primitive descriptor constructor is a zero memory descriptor, the primitive will behave the same as in LSTM primitive without peephole.

LSTM with Projection

A four-gate long short-term memory recurrent cell with projection initialized with `dnnl::lstm_forward::primitive_desc` or `dnnl::lstm_backward::primitive_desc` as in the following example.

```
auto lstm_pd = dnnl::lstm_forward::primitive_desc(engine, aprop,
    direction, src_layer_desc, src_iter_h_desc, src_iter_c_desc,
    weights_layer_desc, weights_iter_desc, weights_peephole_desc,
    weights_projection_desc, bias_desc, dst_layer_desc,
    dst_iter_h_desc, dst_iter_c_desc, attr);
```

Similarly to vanilla LSTM, we implicitly require the order of the gates to be i , f , \tilde{c} , and o for all tensors with a dimension depending on the gates. The following equation gives the mathematical description of these gates and output for the

forward pass (for simplicity, LSTM without peephole is shown):

$$\begin{aligned}i_t &= \sigma(W_i \cdot h_{t,l-1} + U_i \cdot h_{t-1,l} + B_i) \\f_t &= \sigma(W_f \cdot h_{t,l-1} + U_f \cdot h_{t-1,l} + B_f) \\ \tilde{c}_t &= \tanh(W_{\tilde{c}} \cdot h_{t,l-1} + U_{\tilde{c}} \cdot h_{t-1,l} + B_{\tilde{c}}) \\c_t &= f_t * c_{t-1} + i_t * \tilde{c}_t \\ \\o_t &= \sigma(W_o \cdot h_{t,l-1} + U_o \cdot h_{t-1,l} + B_o) \\h_t &= R \cdot (\tanh(c_t) * o_t)\end{aligned}$$

where R is stored in `weights_projection`, and the other parameters are the same as in vanilla LSTM.

Note: If the `weights_projection_desc` passed to the primitive descriptor constructor is a zero memory descriptor, the primitive will behave the same as in LSTM primitive without projection.

GRU

A three-gate gated recurrent unit cell, initialized with `dnnl::gru_forward::primitive_desc` or `dnnl::gru_backward::primitive_desc` as in the following example.

```
auto gru_pd = dnnl::gru_forward::primitive_desc(engine, aprop,
direction, src_layer_desc, src_iter_desc, weights_layer_desc,
weights_iter_desc, bias_desc, dst_layer_desc, dst_iter_desc,
attr);
```

Note that for all tensors with a dimension depending on the gates number, we implicitly require the order of these gates to be: u , r , and o . The following equation gives the mathematical definition of these gates.

$$\begin{aligned}u_t &= \sigma(W_u \cdot h_{t,l-1} + U_u \cdot h_{t-1,l} + B_u) \\r_t &= \sigma(W_r \cdot h_{t,l-1} + U_r \cdot h_{t-1,l} + B_r) \\o_t &= \tanh(W_o \cdot h_{t,l-1} + U_o \cdot (r_t * h_{t-1,l}) + B_o) \\h_t &= u_t * h_{t-1,l} + (1 - u_t) * o_t\end{aligned}$$

where W_* are in `weights_layer`, U_* are in `weights_iter`, and B_* are stored in `bias`.

Note: If you need to replace u_t by $(1 - u_t)$ when computing h_t , you can achieve this by multiplying W_u , U_u and B_u by -1 . This is possible as $u_t = \sigma(W_u \cdot h_{t,l-1} + U_u \cdot h_{t-1,l} + B_u)$, and $1 \checkmark \sigma(a) = \sigma(-a)$.

Linear-Before-Reset GRU

A three-gate gated recurrent unit cell with linear layer applied before the reset gate, initialized with `dnnl::lbr_gru_forward::primitive_desc` or `dnnl::lbr_gru_backward::primitive_desc` as in the following example.

```
auto lbr_gru_pd = dnnl::lbr_gru_forward::primitive_desc(engine,
aprop, direction, src_layer_desc, src_iter_desc,
weights_layer_desc, weights_iter_desc, bias_desc,
dst_layer_desc, dst_iter_desc, attr);
```

The following equation describes the mathematical behavior of the Linear-Before-Reset GRU cell.

$$\begin{aligned} u_t &= \sigma(W_u \cdot h_{t,l-1} + U_u \cdot h_{t-1,l} + B_u) \\ r_t &= \sigma(W_r \cdot h_{t,l-1} + U_r \cdot h_{t-1,l} + B_r) \\ o_t &= \tanh(W_o \cdot h_{t,l-1} + r_t * (U_o \cdot h_{t-1,l} + B_o) + B_o) \\ h_t &= u_t * h_{t-1,l} + (1 - u_t) * o_t \end{aligned}$$

Note that for all tensors with a dimension depending on the gates number, except the bias, we implicitly require the order of these gates to be u , r , and o . For the bias tensor, we implicitly require the order of the gates to be u , r , o , and u' .

Note: If you need to replace u_t by $(1 - u_t)$ when computing h_t , you can achieve this by multiplying W_u , U_u and B_u by -1 . This is possible as $u_t = \sigma(W_u \cdot h_{t,l-1} + U_u \cdot h_{t-1,l} + B_u)$, and $1 - \sigma(a) = \sigma(-a)$.

AUGRU

A three-gate gated recurrent unit cell, initialized with `dnnl::augru_forward::primitive_desc` or `dnnl::augru_backward::primitive_desc` as in the following example.

```
auto augru_pd = dnnl::augru_forward::primitive_desc(engine, apropr,
    direction, src_layer_desc, src_iter_desc, attention_desc,
    weights_layer_desc, weights_iter_desc, bias_desc,
    dst_layer_desc, dst_iter_desc, attr);
```

Note that for all tensors with a dimension depending on the gate number, we implicitly require the order of these gates to be u , r , and o . The following equation gives the mathematical definition of these gates.

$$\begin{aligned} u_t &= \sigma(W_u \cdot h_{t,l-1} + U_u \cdot h_{t-1,l} + B_u) \\ r_t &= \sigma(W_r \cdot h_{t,l-1} + U_r \cdot h_{t-1,l} + B_r) \\ o_t &= \tanh(W_o \cdot h_{t,l-1} + U_o \cdot (r_t * h_{t-1,l}) + B_o) \\ \tilde{u}_t &= (1 - a_t) * u_t \\ h_t &= \tilde{u}_t * h_{t-1,l} + (1 - \tilde{u}_t) * o_t \end{aligned}$$

where W_* are in `weightslayer`, U_* are in `weightsiter`, and B_* are stored in `bias`.

Linear-Before-Reset AUGRU

A three-gate gated recurrent unit cell with linear layer applied before the reset gate, initialized with `dnnl::lbr_augru_forward::primitive_desc` or `dnnl::lbr_augru_backward::primitive_desc` as in the following example.

```
auto lbr_augru_pd =
    dnnl::lbr_augru_forward::primitive_desc(engine, apropr,
    direction, src_layer_desc, src_iter_desc, attention_desc,
    weights_layer_desc, weights_iter_desc, bias_desc,
    dst_layer_desc, dst_iter_desc, attr);
```

The following equation describes the mathematical behavior of the Linear-Before-Reset AUGRU cell.

$$\begin{aligned}
 u_t &= \sigma(W_u \cdot h_{t,l-1} + U_u \cdot h_{t-1,l} + B_u) \\
 r_t &= \sigma(W_r \cdot h_{t,l-1} + U_r \cdot h_{t-1,l} + B_r) \\
 o_t &= \tanh(W_o \cdot h_{t,l-1} + r_t * (U_o \cdot h_{t-1,l} + B_{u'}) + B_o) \\
 \tilde{u}_t &= (1 - a_t) * u_t \\
 h_t &= \tilde{u}_t * h_{t-1,l} + (1 - \tilde{u}_t) * o_t
 \end{aligned}$$

Note that for all tensors with a dimension depending on the gate number, except the bias, we implicitly require the order of these gates to be u , r , and o . For the bias tensor, we implicitly require the order of the gates to be u , r , o , and u' .

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src_layer	<i>DNNL_ARG_SRC_LAYER</i>
src_iter	<i>DNNL_ARG_SRC_ITER</i>
src_iter_c	<i>DNNL_ARG_SRC_ITER_C</i>
weights_layer	<i>DNNL_ARG_WEIGHTS_LAYER</i>
weights_iter	<i>DNNL_ARG_WEIGHTS_ITER</i>
weights_peephole	<i>DNNL_ARG_WEIGHTS_PEEPHOLE</i>
weights_projection	<i>DNNL_ARG_WEIGHTS_PROJECTION</i>
bias	<i>DNNL_ARG_BIAS</i>
dst_layer	<i>DNNL_ARG_DST_LAYER</i>
dst_iter	<i>DNNL_ARG_DST_ITER</i>
dst_iter_c	<i>DNNL_ARG_DST_ITER_C</i>
workspace	<i>DNNL_ARG_WORKSPACE</i>
diff_src_layer	<i>DNNL_ARG_DIFF_SRC_LAYER</i>
diff_src_iter	<i>DNNL_ARG_DIFF_SRC_ITER</i>
diff_src_iter_c	<i>DNNL_ARG_DIFF_SRC_ITER_C</i>
diff_weights_layer	<i>DNNL_ARG_DIFF_WEIGHTS_LAYER</i>
diff_weights_iter	<i>DNNL_ARG_DIFF_WEIGHTS_ITER</i>
diff_weights_peephole	<i>DNNL_ARG_DIFF_WEIGHTS_PEEPHOLE</i>
diff_weights_projection	<i>DNNL_ARG_DIFF_WEIGHTS_PROJECTION</i>
diff_bias	<i>DNNL_ARG_DIFF_BIAS</i>
diff_dst_layer	<i>DNNL_ARG_DIFF_DST_LAYER</i>
diff_dst_iter	<i>DNNL_ARG_DIFF_DST_ITER</i>
diff_dst_iter_c	<i>DNNL_ARG_DIFF_DST_ITER_C</i>

Operation Details

N/A

Data Types Support

The following table lists the combination of data types that should be supported by the RNN primitive for each input and output memory object.

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Propagation	Cell Function	Input Data	Recurrent Data (1)	Weights	Bias	Output Data
Forward / Backward	All	<i>f32</i>	<i>f32</i>	<i>f32</i>	<i>f32</i>	<i>f32</i>
Forward / Backward (2)	All (3)	<i>bf16</i>	<i>bf16</i>	<i>bf16</i>	<i>f32</i>	<i>bf16</i>
Forward	All (3)	<i>f16</i>	<i>f16</i>	<i>f16</i>	<i>f16</i>	<i>f16</i>
Forward inference	Vanilla LSTM	<i>u8</i>	<i>u8</i>	<i>s8</i>	<i>f32</i>	<i>u8, f32</i>

(1) With LSTM and Peephole LSTM cells, the cell state data type is always `f32`.

(2) In backward propagation, all `diff_*` tensors are in `f32`.

(3) Projection LSTM is not defined yet.

Data Representation

In the oneDNN programming model, the RNN primitive is one of a few that support the placeholder memory format `#dnnl::memory::format_tag::any` (shortened to `any` from now on) and can define data and weight memory objects format based on the primitive parameters.

The following table summarizes the data layouts supported by the RNN primitive.

Input/Output Data	Recurrent Data	Layer and Iteration Weights	Peephole and Bias Weights	Projection Weights	LSTM Weights
<i>any</i>	<i>any</i>	<i>any</i>	<i>ldgo</i>	<i>any, ldio</i> (Forward propagation)	
<i>ntc, tnc</i>	<i>ldnc</i>	<i>ldigo, ldgoi</i>	<i>ldgo</i>	<i>any, ldio</i> (Forward propagation)	

While an RNN primitive can be created with memory formats specified explicitly, the performance is likely to be sub-optimal. When using `any` it is necessary to first create an RNN primitive descriptor and then query it for the actual data and weight memory objects formats.

Note: The RNN primitive should support padded tensors and views. So even if two memory descriptors share the same data layout, they might still be different.

Post-ops and Attributes

Currently post-ops and attributes are only used by the int8 variant of LSTM.

API

enum class `dnnl::rnn_flags` : unsigned
RNN cell flags.

Values:

enumerator `undef`
Undefined RNN flags.

enum class `dnnl::rnn_direction`
A direction of RNN primitive execution.

Values:

enumerator `undef`
Undefined RNN direction.

enumerator `unidirectional_left2right`
Unidirectional execution of RNN primitive from left to right.

enumerator `unidirectional_right2left`
Unidirectional execution of RNN primitive from right to left.

enumerator `bidirectional_concat`
Bidirectional execution of RNN primitive with concatenation of the results.

enumerator `bidirectional_sum`
Bidirectional execution of RNN primitive with summation of the results.

enumerator `unidirectional`
Alias for `dnnl::rnn_direction::unidirectional_left2right`.

struct `dnnl::vanilla_rnn_forward` : public `dnnl::primitive`
Vanilla RNN forward propagation primitive.

Public Functions

`vanilla_rnn_forward()`
Default constructor. Produces an empty object.

`vanilla_rnn_forward(const primitive_desc &pd)`
Constructs a vanilla RNN forward propagation primitive.

Parameters `pd` – Primitive descriptor for a vanilla RNN forward propagation primitive.

struct `primitive_desc` : public `dnnl::rnn_primitive_desc_base`
Primitive descriptor for a vanilla RNN forward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* activation, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a vanilla RNN forward propagation primitive.

The following arguments may point to a zero memory descriptor:

- src_iter_desc,
- bias_desc,
- dst_iter_desc.

This would then indicate that the RNN forward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors except `src_iter_desc` can be initialized with an `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **activation** – Activation kind. Possible values are `dnnl::algorithm::eltwise_relu`, `dnnl::algorithm::eltwise_tanh`, or `dnnl::algorithm::eltwise_logistic`.
- **direction** – RNN direction. See `dnnl::rnn_direction` for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* activation, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, float alpha, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a vanilla RNN forward propagation primitive with alpha parameter.

The following arguments may point to a zero memory descriptor:

- src_iter_desc,
- bias_desc,

- `dst_iter_desc`.

This would then indicate that the RNN forward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors except `src_iter_desc` can be initialized with an `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **engine** – Engine to use.
- **prop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **activation** – Activation kind. Possible values are `dnnl::algorithm::eltwise_relu`, `dnnl::algorithm::eltwise_tanh`, or `dnnl::algorithm::eltwise_logistic`.
- **direction** – RNN direction. See `dnnl::rnn_direction` for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **alpha** – Negative slope if activation is `dnnl::algorithm::eltwise_relu`.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc src_layer_desc()` const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

`memory::desc src_iter_desc()` const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

`memory::desc weights_layer_desc()` const

Returns weights layer memory descriptor.

Returns Weights layer memory descriptor.

`memory::desc weights_iter_desc()` const

Returns weights iteration memory descriptor.

Returns Weights iteration memory descriptor.

`memory::desc bias_desc()` const

Returns bias memory descriptor.

Returns Bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

`memory::desc dst_layer_desc()` const

Returns destination layer memory descriptor.

Returns Destination layer memory descriptor.

`memory::desc dst_iter_desc()` const

Returns destination iteration memory descriptor.

Returns Destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

algorithm **get_cell_kind()** const

Returns an RNN cell kind parameter.

Returns An RNN cell kind parameter.

Returns *dnnl::algorithm::undef* if the primitive does not have an RNN cell kind parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

algorithm **get_activation_kind()** const

Returns an RNN activation kind parameter.

Returns An RNN activation kind parameter.

Returns *dnnl::algorithm::undef* if the primitive does not have an RNN activation kind parameter.

rnn_direction **get_direction()** const

Returns an RNN direction parameter.

Returns An RNN direction parameter.

Returns *dnnl::rnn_direction::undef* if the primitive does not have an RNN direction parameter.

float **get_alpha()** const

Returns an alpha.

Returns An alpha.

Returns Zero if the primitive does not have an alpha parameter.

float **get_beta()** const

Returns a beta.

Returns A beta.

Returns Zero if the primitive does not have a beta parameter.

struct *dnnl::vanilla_rnn_backward* : public *dnnl::primitive*

Vanilla RNN backward propagation primitive.

Public Functions

vanilla_rnn_backward()

Default constructor. Produces an empty object.

vanilla_rnn_backward(const *primitive_desc* &pd)

Constructs a vanilla RNN backward propagation primitive.

Parameters **pd** – Primitive descriptor for a vanilla RNN backward propagation primitive.

struct **primitive_desc** : public *dnnl::rnn_primitive_desc_base*

Primitive descriptor for an RNN backward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* activation, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *memory::desc* &diff_src_layer_desc, const *memory::desc* &diff_src_iter_desc, const *memory::desc* &diff_weights_layer_desc, const *memory::desc* &diff_weights_iter_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_layer_desc, const *memory::desc* &diff_dst_iter_desc, const *vanilla_rnn_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a vanilla RNN backward propagation primitive.

The following arguments may point to a zero memory descriptor:

- *src_iter_desc* together with *diff_src_iter_desc*,
- *bias_desc* together with *diff_bias_desc*,
- *dst_iter_desc* together with *diff_dst_iter_desc*.

This would then indicate that the RNN backward propagation primitive should not use the respective data and should use zero values instead.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Must be *dnnl::prop_kind::backward*.
- **activation** – Activation kind. Possible values are *dnnl::algorithm::eltwise_relu*, *dnnl::algorithm::eltwise_tanh*, or *dnnl::algorithm::eltwise_logistic*.
- **direction** – RNN direction. See *dnnl::rnn_direction* for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **diff_src_layer_desc** – Memory descriptor for the diff of input vector.
- **diff_src_iter_desc** – Memory descriptor for the diff of input recurrent hidden state vector.
- **diff_weights_layer_desc** – Memory descriptor for the diff of weights applied to the layer input.
- **diff_weights_iter_desc** – Memory descriptor for the diff of weights applied to the recurrent input.
- **diff_bias_desc** – Diff bias memory descriptor.
- **diff_dst_layer_desc** – Memory descriptor for the diff of output vector.
- **diff_dst_iter_desc** – Memory descriptor for the diff of output recurrent hidden state vector.
- **hint_fwd_pd** – Primitive descriptor for a vanilla RNN forward propagation primitive. It is used as a hint for deciding which memory format to use.

- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *algorithm* activation, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *memory::desc* &diff_src_layer_desc, const *memory::desc* &diff_src_iter_desc, const *memory::desc* &diff_weights_layer_desc, const *memory::desc* &diff_weights_iter_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_layer_desc, const *memory::desc* &diff_dst_iter_desc, float alpha, const *vanilla_rnn_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a vanilla RNN backward propagation primitive with an alpha parameter.

The following arguments may point to a zero memory descriptor:

- **src_iter_desc** together with **diff_src_iter_desc**,
- **bias_desc** together with **diff_bias_desc**,
- **dst_iter_desc** together with **diff_dst_iter_desc**.

This would then indicate that the RNN backward propagation primitive should not use the respective data and should use zero values instead.

Note: All the memory descriptors may be initialized with the *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Must be *dnnl::prop_kind::backward*.
- **activation** – Activation kind. Possible values are *dnnl::algorithm::eltwise_relu*, *dnnl::algorithm::eltwise_tanh*, or *dnnl::algorithm::eltwise_logistic*.
- **direction** – RNN direction. See *dnnl::rnn_direction* for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **diff_src_layer_desc** – Memory descriptor for the diff of input vector.
- **diff_src_iter_desc** – Memory descriptor for the diff of input recurrent hidden state vector.
- **diff_weights_layer_desc** – Memory descriptor for the diff of weights applied to the layer input.
- **diff_weights_iter_desc** – Memory descriptor for the diff of weights applied to the recurrent input.
- **diff_bias_desc** – Diff bias memory descriptor.
- **diff_dst_layer_desc** – Memory descriptor for the diff of output vector.
- **diff_dst_iter_desc** – Memory descriptor for the diff of output recurrent hidden state vector.
- **alpha** – Negative slope if activation is *dnnl::algorithm::eltwise_relu*.

- **hint_fwd_pd** – Primitive descriptor for a vanilla RNN forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_layer_desc()** const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

memory::desc **src_iter_desc()** const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **weights_layer_desc()** const

Returns weights layer memory descriptor.

Returns Weights layer memory descriptor.

memory::desc **weights_iter_desc()** const

Returns weights iteration memory descriptor.

Returns Weights iteration memory descriptor.

memory::desc **bias_desc()** const

Returns bias memory descriptor.

Returns Bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

memory::desc **dst_layer_desc()** const

Returns destination layer memory descriptor.

Returns Destination layer memory descriptor.

memory::desc **dst_iter_desc()** const

Returns destination iteration memory descriptor.

Returns Destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

memory::desc **diff_src_layer_desc()** const

Returns diff source layer memory descriptor.

Returns Diff source layer memory descriptor.

memory::desc **diff_src_iter_desc()** const

Returns diff source iteration memory descriptor.

Returns Diff source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source iteration parameter.

memory::desc **diff_weights_layer_desc()** const

Returns diff weights layer memory descriptor.

Returns Diff weights layer memory descriptor.

memory::desc **diff_weights_iter_desc()** const

Returns diff weights iteration memory descriptor.

Returns Diff weights iteration memory descriptor.

memory::desc **diff_bias_desc()** const

Returns diff bias memory descriptor.

Returns Diff bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff bias parameter.

memory::desc **diff_dst_layer_desc()** const

Returns diff destination layer memory descriptor.

Returns Diff destination layer memory descriptor.

memory::desc **diff_dst_iter_desc()** const

Returns diff destination iteration memory descriptor.

Returns Diff destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination iteration parameter.

algorithm **get_cell_kind()** const

Returns an RNN cell kind parameter.

Returns An RNN cell kind parameter.

Returns *dnnl::algorithm::undef* if the primitive does not have an RNN cell kind parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

algorithm **get_activation_kind()** const

Returns an RNN activation kind parameter.

Returns An RNN activation kind parameter.

Returns *dnnl::algorithm::undef* if the primitive does not have an RNN activation kind parameter.

rnn_direction **get_direction()** const

Returns an RNN direction parameter.

Returns An RNN direction parameter.

Returns *dnnl::rnn_direction::undef* if the primitive does not have an RNN direction parameter.

float **get_alpha()** const

Returns an alpha.

Returns An alpha.

Returns Zero if the primitive does not have an alpha parameter.

float **get_beta()** const

Returns a beta.

Returns A beta.

Returns Zero if the primitive does not have a beta parameter.

```
struct dnnl::lstm_forward : public dnnl::primitive
    LSTM forward propagation primitive.
```

Public Functions

`lstm_forward()`

Default constructor. Produces an empty object.

`lstm_forward(const primitive_desc &pd)`

Constructs an LSTM forward propagation primitive.

Parameters `pd` – Primitive descriptor for an LSTM forward propagation primitive.

struct **primitive_desc** : public `dnnl::rnn_primitive_desc_base`

Primitive descriptor for an LSTM forward propagation primitive.

Public Functions

`primitive_desc() = default`

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &src_iter_c_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &weights_peephole_desc, const *memory::desc* &weights_projection_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *memory::desc* &dst_iter_c_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an LSTM (with or without peephole and with or without projection) forward propagation primitive.

The following arguments may point to a zero memory descriptor:

- `src_iter_desc` together with `src_iter_c_desc`,
- `weights_peephole_desc`,
- `bias_desc`,
- `dst_iter_desc` together with `dst_iter_c_desc`.

This would then indicate that the LSTM forward propagation primitive should not use them and should default to zero values instead.

The `weights_projection_desc` may point to a zero memory descriptor. This would then indicate that the LSTM doesn't have recurrent projection layer.

Note: All memory descriptors can be initialized with an `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **prop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **direction** – RNN direction. See `dnnl::rnn_direction` for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **src_iter_c_desc** – Memory descriptor for the input recurrent cell state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.

- **weights_peephole_desc** – Memory descriptor for the weights applied to the cell states (according to the Peephole LSTM formula).
- **weights_projection_desc** – Memory descriptor for the weights applied to the hidden states to get the recurrent projection (according to the Projection LSTM formula).
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **dst_iter_c_desc** – Memory descriptor for the output recurrent cell state vector.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &engine, *prop_kind* aprop_kind, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &src_iter_c_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &weights_peephole_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *memory::desc* &dst_iter_c_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an LSTM (with or without peephole) forward propagation primitive.

The following arguments may point to a zero memory descriptor:

- **src_iter_desc** together with **src_iter_c_desc**,
- **weights_peephole_desc**,
- **bias_desc**,
- **dst_iter_desc** together with **dst_iter_c_desc**.

This would then indicate that the LSTM forward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors can be initialized with an *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **engine** – Engine to use.
- **prop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **direction** – RNN direction. See *dnnl::rnn_direction* for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **src_iter_c_desc** – Memory descriptor for the input recurrent cell state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **weights_peephole_desc** – Memory descriptor for the weights applied to the cell states (according to the Peephole LSTM formula).
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **dst_iter_c_desc** – Memory descriptor for the output recurrent cell state vector.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and

defaults to false.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &src_iter_c_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *memory::desc* &dst_iter_c_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for an LSTM forward propagation primitive.

The following arguments may point to a zero memory descriptor:

- *src_iter_desc* together with *src_iter_c_desc*,
- *bias_desc*,
- *dst_iter_desc* together with *dst_iter_c_desc*.

This would then indicate that the LSTM forward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors can be initialized with an *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **direction** – RNN direction. See *dnnl::rnn_direction* for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **src_iter_c_desc** – Memory descriptor for the input recurrent cell state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **dst_iter_c_desc** – Memory descriptor for the output recurrent cell state vector.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_layer_desc**() const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

memory::desc **src_iter_desc**() const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **src_iter_c_desc**() const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **weights_layer_desc**() const
Returns weights layer memory descriptor.
Returns Weights layer memory descriptor.

memory::desc **weights_iter_desc**() const
Returns weights iteration memory descriptor.
Returns Weights iteration memory descriptor.

memory::desc **weights_peephole_desc**() const
Returns weights peephole memory descriptor.
Returns Weights peephole memory descriptor.

memory::desc **weights_projection_desc**() const
Returns weights projection memory descriptor.
Returns Weights projection memory descriptor.

memory::desc **bias_desc**() const
Returns bias memory descriptor.
Returns Bias memory descriptor.
Returns A zero memory descriptor if the primitive does not have a bias parameter.

memory::desc **dst_layer_desc**() const
Returns destination layer memory descriptor.
Returns Destination layer memory descriptor.

memory::desc **dst_iter_desc**() const
Returns destination iteration memory descriptor.
Returns Destination iteration memory descriptor.
Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

memory::desc **dst_iter_c_desc**() const
Returns source iteration memory descriptor.
Returns Source iteration memory descriptor.
Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **workspace_desc**() const
Returns the workspace memory descriptor.
Returns Workspace memory descriptor.
Returns A zero memory descriptor if the primitive does not require workspace parameter.

algorithm **get_cell_kind**() const
Returns an RNN cell kind parameter.
Returns An RNN cell kind parameter.
Returns *dnnl::algorithm::undef* if the primitive does not have an RNN cell kind parameter.

prop_kind **get_prop_kind**() const
Returns a propagation kind.
Returns A propagation kind.
Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

rnn_direction **get_direction**() const
Returns an RNN direction parameter.
Returns An RNN direction parameter.
Returns *dnnl::rnn_direction::undef* if the primitive does not have an RNN direction parameter.

```
struct dnnl::lstm_backward : public dnnl::primitive
    LSTM backward propagation primitive.
```

Public Functions

`lstm_backward()`

Default constructor. Produces an empty object.

`lstm_backward(const primitive_desc &pd)`

Constructs an LSTM backward propagation primitive.

Parameters `pd` – Primitive descriptor for an LSTM backward propagation primitive.

```
struct primitive_desc : public dnnl::rnn_primitive_desc_base
    Primitive descriptor for an LSTM backward propagation primitive.
```

Public Functions

`primitive_desc() = default`

Default constructor. Produces an empty object.

```
primitive_desc(const engine &aengine, prop_kind aprop_kind, rnn_direction direction, const
    memory::desc &src_layer_desc, const memory::desc &src_iter_desc, const
    memory::desc &src_iter_c_desc, const memory::desc &weights_layer_desc, const
    memory::desc &weights_iter_desc, const memory::desc &weights_peephole_desc,
    const memory::desc &weights_projection_desc, const memory::desc &bias_desc,
    const memory::desc &dst_layer_desc, const memory::desc &dst_iter_desc, const
    memory::desc &dst_iter_c_desc, const memory::desc &diff_src_layer_desc, const
    memory::desc &diff_src_iter_desc, const memory::desc &diff_src_iter_c_desc, const
    memory::desc &diff_weights_layer_desc, const memory::desc
    &diff_weights_iter_desc, const memory::desc &diff_weights_peephole_desc, const
    memory::desc &diff_weights_projection_desc, const memory::desc &diff_bias_desc,
    const memory::desc &diff_dst_layer_desc, const memory::desc &diff_dst_iter_desc,
    const memory::desc &diff_dst_iter_c_desc, const lstm_forward::primitive_desc
    &hint_fwd_pd, const primitive_attr &attr = default_attr(), bool allow_empty = false)
```

Constructs an LSTM (with or without peephole and with or without projection) primitive descriptor for backward propagation using `prop_kind`, `direction`, and memory descriptors.

The following arguments may point to a zero memory descriptor:

- `src_iter_desc` together with `src_iter_c_desc`, `diff_src_iter_desc`, and `diff_src_iter_c_desc`,
- `weights_peephole_desc` together with `diff_weights_peephole_desc`
- `bias_desc` together with `diff_bias_desc`,
- `dst_iter_desc` together with `dst_iter_c_desc`, `diff_dst_iter_desc`, and `diff_dst_iter_c_desc`.

This would then indicate that the LSTM backward propagation primitive should not use them and should default to zero values instead.

The `weights_projection_desc` together with `diff_weights_projection_desc` may point to a zero memory descriptor. This would then indicate that the LSTM doesn't have recurrent projection layer.

Note: All memory descriptors can be initialized with `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- `aengine` – Engine to use.
- `prop_kind` – Propagation kind. Must be `dnnl::prop_kind::backward`.

- **direction** – RNN direction. See *dnnl::rnn_direction* for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **src_iter_c_desc** – Memory descriptor for the input recurrent cell state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **weights_peephole_desc** – Memory descriptor for the weights applied to the cell states (according to the Peephole LSTM formula).
- **weights_projection_desc** – Memory descriptor for the weights applied to the hidden states to get the recurrent projection (according to the Projection LSTM formula).
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **dst_iter_c_desc** – Memory descriptor for the output recurrent cell state vector.
- **diff_src_layer_desc** – Memory descriptor for the diff of input vector.
- **diff_src_iter_desc** – Memory descriptor for the diff of input recurrent hidden state vector.
- **diff_src_iter_c_desc** – Memory descriptor for the diff of input recurrent cell state vector.
- **diff_weights_layer_desc** – Memory descriptor for the diff of weights applied to the layer input.
- **diff_weights_iter_desc** – Memory descriptor for the diff of weights applied to the recurrent input.
- **diff_weights_peephole_desc** – Memory descriptor for the diff of weights applied to the cell states (according to the Peephole LSTM formula).
- **diff_weights_projection_desc** – Memory descriptor for the diff of weights applied to the hidden states to get the recurrent projection (according to the Projection LSTM formula).
- **diff_bias_desc** – Diff bias memory descriptor.
- **diff_dst_layer_desc** – Memory descriptor for the diff of output vector.
- **diff_dst_iter_desc** – Memory descriptor for the diff of output recurrent hidden state vector.
- **diff_dst_iter_c_desc** – Memory descriptor for the diff of output recurrent cell state vector.
- **hint_fwd_pd** – Primitive descriptor for an LSTM forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

```
primitive_desc(const engine &aengine, prop_kind aprop_kind, rnn_direction direction, const
memory::desc &src_layer_desc, const memory::desc &src_iter_desc, const

memory::desc &diff_dst_iter_c_desc, const lstm_forward::primitive_desc
&hint_fwd_pd, const primitive_attr &attr = default_attr(), bool allow_empty = false)
```

Constructs an LSTM (with or without peephole) primitive descriptor for backward propagation using `prop_kind`, `direction`, and memory descriptors.

The following arguments may point to a zero memory descriptor:

- `src_iter_desc` together with `src_iter_c_desc`, `diff_src_iter_desc`, and `diff_src_iter_c_desc`,
- `weights_peephole_desc` together with `diff_weights_peephole_desc`
- `bias_desc` together with `diff_bias_desc`,
- `dst_iter_desc` together with `dst_iter_c_desc`, `diff_dst_iter_desc`, and `diff_dst_iter_c_desc`.

This would then indicate that the LSTM backward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors may be initialized with `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **aengine** – Engine to use.
- **prop_kind** – Propagation kind. Must be `dnnl::prop_kind::backward`.
- **direction** – RNN direction. See `dnnl::rnn_direction` for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **src_iter_c_desc** – Memory descriptor for the input recurrent cell state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **weights_peephole_desc** – Memory descriptor for the weights applied to the cell states (according to the Peephole LSTM formula).
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **dst_iter_c_desc** – Memory descriptor for the output recurrent cell state vector.
- **diff_src_layer_desc** – Memory descriptor for the diff of input vector.
- **diff_src_iter_desc** – Memory descriptor for the diff of input recurrent hidden state vector.
- **diff_src_iter_c_desc** – Memory descriptor for the diff of input recurrent cell state vector.
- **diff_weights_layer_desc** – Memory descriptor for the diff of weights applied to the layer input.
- **diff_weights_iter_desc** – Memory descriptor for the diff of weights applied to the

recurrent input.

- **diff_weights_peephole_desc** – Memory descriptor for the diff of weights applied to the cell states (according to the Peephole LSTM formula).
- **diff_bias_desc** – Diff bias memory descriptor.
- **diff_dst_layer_desc** – Memory descriptor for the diff of output vector.
- **diff_dst_iter_desc** – Memory descriptor for the diff of output recurrent hidden state vector.
- **diff_dst_iter_c_desc** – Memory descriptor for the diff of output recurrent cell state vector.
- **hint_fwd_pd** – Primitive descriptor for an LSTM forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

primitive_desc(const *engine* &engine, *prop_kind* aprop_kind, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &src_iter_c_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *memory::desc* &dst_iter_c_desc, const *memory::desc* &diff_src_layer_desc, const *memory::desc* &diff_src_iter_desc, const *memory::desc* &diff_src_iter_c_desc, const *memory::desc* &diff_weights_layer_desc, const *memory::desc* &diff_weights_iter_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_layer_desc, const *memory::desc* &diff_dst_iter_desc, const *memory::desc* &diff_dst_iter_c_desc, const *lstm_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs an LSTM primitive descriptor for backward propagation using *prop_kind*, *direction*, and memory descriptors.

The following arguments may point to a zero memory descriptor:

- *src_iter_desc* together with *src_iter_c_desc*, *diff_src_iter_desc*, and *diff_src_iter_c_desc*,
- *bias_desc* together with *diff_bias_desc*,
- *dst_iter_desc* together with *dst_iter_c_desc*, *diff_dst_iter_desc*, and *diff_dst_iter_c_desc*.

This would then indicate that the LSTM backward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors may be initialized with *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **engine** – Engine to use.
- **aprop_kind** – Propagation kind. Must be *dnnl::prop_kind::backward*.
- **direction** – RNN direction. See *dnnl::rnn_direction* for more info.
- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **src_iter_c_desc** – Memory descriptor for the input recurrent cell state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **bias_desc** – Bias memory descriptor.

- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **dst_iter_c_desc** – Memory descriptor for the output recurrent cell state vector.
- **diff_src_layer_desc** – Memory descriptor for the diff of input vector.
- **diff_src_iter_desc** – Memory descriptor for the diff of input recurrent hidden state vector.
- **diff_src_iter_c_desc** – Memory descriptor for the diff of input recurrent cell state vector.
- **diff_weights_layer_desc** – Memory descriptor for the diff of weights applied to the layer input.
- **diff_weights_iter_desc** – Memory descriptor for the diff of weights applied to the recurrent input.
- **diff_bias_desc** – Diff bias memory descriptor.
- **diff_dst_layer_desc** – Memory descriptor for the diff of output vector.
- **diff_dst_iter_desc** – Memory descriptor for the diff of output recurrent hidden state vector.
- **diff_dst_iter_c_desc** – Memory descriptor for the diff of output recurrent cell state vector.
- **hint_fwd_pd** – Primitive descriptor for a convolution forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_layer_desc**() const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

memory::desc **src_iter_desc**() const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **src_iter_c_desc**() const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **weights_layer_desc**() const

Returns weights layer memory descriptor.

Returns Weights layer memory descriptor.

memory::desc **weights_iter_desc**() const

Returns weights iteration memory descriptor.

Returns Weights iteration memory descriptor.

memory::desc **weights_peephole_desc**() const

Returns weights peephole memory descriptor.

Returns Weights peephole memory descriptor.

memory::desc **weights_projection_desc**() const

Returns weights projection memory descriptor.

Returns Weights projection memory descriptor.

memory::desc **bias_desc**() const

Returns bias memory descriptor.

Returns Bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

memory::desc **dst_layer_desc**() const

Returns destination layer memory descriptor.

Returns Destination layer memory descriptor.

memory::desc **dst_iter_desc**() const

Returns destination iteration memory descriptor.

Returns Destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

memory::desc **dst_iter_c_desc**() const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **workspace_desc**() const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

memory::desc **diff_src_layer_desc**() const

Returns diff source layer memory descriptor.

Returns Diff source layer memory descriptor.

memory::desc **diff_src_iter_desc**() const

Returns diff source iteration memory descriptor.

Returns Diff source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source iteration parameter.

memory::desc **diff_src_iter_c_desc**() const

Returns diff source recurrent cell state memory descriptor.

Returns Diff source recurrent cell state memory descriptor.

memory::desc **diff_weights_layer_desc**() const

Returns diff weights layer memory descriptor.

Returns Diff weights layer memory descriptor.

memory::desc **diff_weights_iter_desc**() const

Returns diff weights iteration memory descriptor.

Returns Diff weights iteration memory descriptor.

memory::desc **diff_weights_peephole_desc**() const

Returns diff weights peephole memory descriptor.

Returns Diff weights peephole memory descriptor.

memory::desc **diff_weights_projection_desc**() const

Returns diff weights projection memory descriptor.

Returns Diff weights projection memory descriptor.

memory::desc **diff_bias_desc**() const

Returns diff bias memory descriptor.

Returns Diff bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff bias parameter.

memory::desc **diff_dst_layer_desc**() const

Returns diff destination layer memory descriptor.

Returns Diff destination layer memory descriptor.

memory::desc **diff_dst_iter_desc()** const
Returns diff destination iteration memory descriptor.
Returns Diff destination iteration memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff destination iteration parameter.

memory::desc **diff_dst_iter_c_desc()** const
Returns diff destination recurrent cell state memory descriptor.
Returns Diff destination recurrent cell state memory descriptor.

algorithm **get_cell_kind()** const
Returns an RNN cell kind parameter.
Returns An RNN cell kind parameter.
Returns *dnnl::algorithm::undef* if the primitive does not have an RNN cell kind parameter.

prop_kind **get_prop_kind()** const
Returns a propagation kind.
Returns A propagation kind.
Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

rnn_direction **get_direction()** const
Returns an RNN direction parameter.
Returns An RNN direction parameter.
Returns *dnnl::rnn_direction::undef* if the primitive does not have an RNN direction parameter.

struct **dnnl::gru_forward** : public *dnnl::primitive*
GRU forward propagation primitive.

Public Functions

gru_forward()
Default constructor. Produces an empty object.

gru_forward(const *primitive_desc* &pd)
Constructs a GRU forward propagation primitive.

Parameters **pd** – Primitive descriptor for a GRU forward propagation primitive.

struct **primitive_desc** : public *dnnl::rnn_primitive_desc_base*
Primitive descriptor for a GRU forward propagation primitive.

Public Functions

primitive_desc() = default
Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)
Constructs a primitive descriptor for a GRU forward propagation primitive.

The following arguments may point to a zero memory descriptor:

- *src_iter_desc*,

- `bias_desc`,
- `dst_iter_desc`.

This would then indicate that the GRU forward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors except `src_iter_desc` may be initialized with an `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **`aengine`** – Engine to use.
- **`aprop_kind`** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **`direction`** – RNN direction. See `dnnl::rnn_direction` for more info.
- **`src_layer_desc`** – Memory descriptor for the input vector.
- **`src_iter_desc`** – Memory descriptor for the input recurrent hidden state vector.
- **`weights_layer_desc`** – Memory descriptor for the weights applied to the layer input.
- **`weights_iter_desc`** – Memory descriptor for the weights applied to the recurrent input.
- **`bias_desc`** – Bias memory descriptor.
- **`dst_layer_desc`** – Memory descriptor for the output vector.
- **`dst_iter_desc`** – Memory descriptor for the output recurrent hidden state vector.
- **`attr`** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **`allow_empty`** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc src_layer_desc()` const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

`memory::desc src_iter_desc()` const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

`memory::desc weights_layer_desc()` const

Returns weights layer memory descriptor.

Returns Weights layer memory descriptor.

`memory::desc weights_iter_desc()` const

Returns weights iteration memory descriptor.

Returns Weights iteration memory descriptor.

`memory::desc bias_desc()` const

Returns bias memory descriptor.

Returns Bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

`memory::desc dst_layer_desc()` const

Returns destination layer memory descriptor.

Returns Destination layer memory descriptor.

`memory::desc dst_iter_desc()` const

Returns destination iteration memory descriptor.

Returns Destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

algorithm **get_cell_kind()** const

Returns an RNN cell kind parameter.

Returns An RNN cell kind parameter.

Returns *dnnl::algorithm::undef* if the primitive does not have an RNN cell kind parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

rnn_direction **get_direction()** const

Returns an RNN direction parameter.

Returns An RNN direction parameter.

Returns *dnnl::rnn_direction::undef* if the primitive does not have an RNN direction parameter.

struct **dnnl::gru_backward** : public *dnnl::primitive*
GRU backward propagation primitive.

Public Functions

gru_backward()

Default constructor. Produces an empty object.

gru_backward(const *primitive_desc* &pd)

Constructs a GRU backward propagation primitive.

Parameters **pd** – Primitive descriptor for a GRU backward propagation primitive.

struct **primitive_desc** : public *dnnl::rnn_primitive_desc_base*
Primitive descriptor for a GRU backward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *memory::desc* &diff_src_layer_desc, const *memory::desc* &diff_src_iter_desc, const *memory::desc* &diff_weights_layer_desc, const *memory::desc* &diff_weights_iter_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_layer_desc, const *memory::desc* &diff_dst_iter_desc, const *gru_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a GRU backward propagation primitive.

The following arguments may point to a zero memory descriptor:

- `src_iter_desc` together with `diff_src_iter_desc`,
- `bias_desc` together with `diff_bias_desc`,
- `dst_iter_desc` together with `diff_dst_iter_desc`.

This would then indicate that the GRU backward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors may be initialized with `dnnl::memory::format_tag::any` value of `format_tag`.

Parameters

- **`aengine`** – Engine to use.
- **`aprop_kind`** – Propagation kind. Must be `dnnl::prop_kind::backward`.
- **`direction`** – RNN direction. See `dnnl::rnn_direction` for more info.
- **`src_layer_desc`** – Memory descriptor for the input vector.
- **`src_iter_desc`** – Memory descriptor for the input recurrent hidden state vector.
- **`weights_layer_desc`** – Memory descriptor for the weights applied to the layer input.
- **`weights_iter_desc`** – Memory descriptor for the weights applied to the recurrent input.
- **`bias_desc`** – Bias memory descriptor.
- **`dst_layer_desc`** – Memory descriptor for the output vector.
- **`dst_iter_desc`** – Memory descriptor for the output recurrent hidden state vector.
- **`diff_src_layer_desc`** – Memory descriptor for the diff of input vector.
- **`diff_src_iter_desc`** – Memory descriptor for the diff of input recurrent hidden state vector.
- **`diff_weights_layer_desc`** – Memory descriptor for the diff of weights applied to the layer input.
- **`diff_weights_iter_desc`** – Memory descriptor for the diff of weights applied to the recurrent input.
- **`diff_bias_desc`** – Diff bias memory descriptor.
- **`diff_dst_layer_desc`** – Memory descriptor for the diff of output vector.
- **`diff_dst_iter_desc`** – Memory descriptor for the diff of output recurrent hidden state vector.
- **`hint_fwd_pd`** – Primitive descriptor for a GRU forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **`attr`** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **`allow_empty`** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc src_layer_desc()` const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

`memory::desc src_iter_desc()` const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

`memory::desc weights_layer_desc()` const

Returns weights layer memory descriptor.

Returns Weights layer memory descriptor.

`memory::desc weights_iter_desc()` const

Returns weights iteration memory descriptor.

Returns Weights iteration memory descriptor.

memory::desc **bias_desc**() const

Returns bias memory descriptor.

Returns Bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

memory::desc **dst_layer_desc**() const

Returns destination layer memory descriptor.

Returns Destination layer memory descriptor.

memory::desc **dst_iter_desc**() const

Returns destination iteration memory descriptor.

Returns Destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

memory::desc **workspace_desc**() const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

memory::desc **diff_src_layer_desc**() const

Returns diff source layer memory descriptor.

Returns Diff source layer memory descriptor.

memory::desc **diff_src_iter_desc**() const

Returns diff source iteration memory descriptor.

Returns Diff source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source iteration parameter.

memory::desc **diff_weights_layer_desc**() const

Returns diff weights layer memory descriptor.

Returns Diff weights layer memory descriptor.

memory::desc **diff_weights_iter_desc**() const

Returns diff weights iteration memory descriptor.

Returns Diff weights iteration memory descriptor.

memory::desc **diff_bias_desc**() const

Returns diff bias memory descriptor.

Returns Diff bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff bias parameter.

memory::desc **diff_dst_layer_desc**() const

Returns diff destination layer memory descriptor.

Returns Diff destination layer memory descriptor.

memory::desc **diff_dst_iter_desc**() const

Returns diff destination iteration memory descriptor.

Returns Diff destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination iteration parameter.

algorithm **get_cell_kind**() const

Returns an RNN cell kind parameter.

Returns An RNN cell kind parameter.

Returns *dnnl::algorithm::undef* if the primitive does not have an RNN cell kind parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

rnn_direction **get_direction()** const

Returns an RNN direction parameter.

Returns An RNN direction parameter.

Returns *dnnl::rnn_direction::undef* if the primitive does not have an RNN direction parameter.

struct *dnnl::lbr_gru_forward* : public *dnnl::primitive*
LBR GRU forward propagation primitive.

Public Functions

lbr_gru_forward()

Default constructor. Produces an empty object.

lbr_gru_forward(const *primitive_desc* &pd)

Constructs an LBR GRU forward propagation primitive.

Parameters **pd** – Primitive descriptor for an LBR GRU forward propagation primitive.

struct **primitive_desc** : public *dnnl::rnn_primitive_desc_base*
Primitive descriptor for an LBR GRU forward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for LBR GRU forward propagation primitive.

The following arguments may point to a zero memory descriptor:

- *src_iter_desc*,
- *bias_desc*,
- *dst_iter_desc*.

This would then indicate that the LBR GRU forward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors except *src_iter_desc* may be initialized with an *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **direction** – RNN direction. See *dnnl::rnn_direction* for more info.

- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_layer_desc()** const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

memory::desc **src_iter_desc()** const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **weights_layer_desc()** const

Returns weights layer memory descriptor.

Returns Weights layer memory descriptor.

memory::desc **weights_iter_desc()** const

Returns weights iteration memory descriptor.

Returns Weights iteration memory descriptor.

memory::desc **bias_desc()** const

Returns bias memory descriptor.

Returns Bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

memory::desc **dst_layer_desc()** const

Returns destination layer memory descriptor.

Returns Destination layer memory descriptor.

memory::desc **dst_iter_desc()** const

Returns destination iteration memory descriptor.

Returns Destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

memory::desc **workspace_desc()** const

Returns the workspace memory descriptor.

Returns Workspace memory descriptor.

Returns A zero memory descriptor if the primitive does not require workspace parameter.

algorithm **get_cell_kind()** const

Returns an RNN cell kind parameter.

Returns An RNN cell kind parameter.

Returns *dnml::algorithm::undef* if the primitive does not have an RNN cell kind parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnml::prop_kind::undef* if the primitive does not have a propagation parameter.

rnn_direction **get_direction()** const
 Returns an RNN direction parameter.
Returns An RNN direction parameter.
Returns *dnnl::rnn_direction::undef* if the primitive does not have an RNN direction parameter.

struct *dnnl::lbr_gru_backward* : public *dnnl::primitive*
 LBR GRU backward propagation primitive.

Public Functions

lbr_gru_backward()
 Default constructor. Produces an empty object.

lbr_gru_backward(const *primitive_desc* &pd)
 Constructs an LBR GRU backward propagation primitive.

Parameters **pd** – Primitive descriptor for an LBR GRU backward propagation primitive.

struct **primitive_desc** : public *dnnl::rnn_primitive_desc_base*
 Primitive descriptor for an LBR GRU backward propagation primitive.

Public Functions

primitive_desc() = default
 Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, *rnn_direction* direction, const *memory::desc* &src_layer_desc, const *memory::desc* &src_iter_desc, const *memory::desc* &weights_layer_desc, const *memory::desc* &weights_iter_desc, const *memory::desc* &bias_desc, const *memory::desc* &dst_layer_desc, const *memory::desc* &dst_iter_desc, const *memory::desc* &diff_src_layer_desc, const *memory::desc* &diff_src_iter_desc, const *memory::desc* &diff_weights_layer_desc, const *memory::desc* &diff_weights_iter_desc, const *memory::desc* &diff_bias_desc, const *memory::desc* &diff_dst_layer_desc, const *memory::desc* &diff_dst_iter_desc, const *gru_forward::primitive_desc* &hint_fwd_pd, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for LBR GRU backward propagation primitive.

The following arguments may point to a zero memory descriptor:

- *src_iter_desc* together with *diff_src_iter_desc*,
- *bias_desc* together with *diff_bias_desc*,
- *dst_iter_desc* together with *diff_dst_iter_desc*.

This would then indicate that the LBR GRU backward propagation primitive should not use them and should default to zero values instead.

Note: All memory descriptors may be initialized with *dnnl::memory::format_tag::any* value of *format_tag*.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Must be *dnnl::prop_kind::backward*.
- **direction** – RNN direction. See *dnnl::rnn_direction* for more info.

- **src_layer_desc** – Memory descriptor for the input vector.
- **src_iter_desc** – Memory descriptor for the input recurrent hidden state vector.
- **weights_layer_desc** – Memory descriptor for the weights applied to the layer input.
- **weights_iter_desc** – Memory descriptor for the weights applied to the recurrent input.
- **bias_desc** – Bias memory descriptor.
- **dst_layer_desc** – Memory descriptor for the output vector.
- **dst_iter_desc** – Memory descriptor for the output recurrent hidden state vector.
- **diff_src_layer_desc** – Memory descriptor for the diff of input vector.
- **diff_src_iter_desc** – Memory descriptor for the diff of input recurrent hidden state vector.
- **diff_weights_layer_desc** – Memory descriptor for the diff of weights applied to the layer input.
- **diff_weights_iter_desc** – Memory descriptor for the diff of weights applied to the recurrent input.
- **diff_bias_desc** – Diff bias memory descriptor.
- **diff_dst_layer_desc** – Memory descriptor for the diff of output vector.
- **diff_dst_iter_desc** – Memory descriptor for the diff of output recurrent hidden state vector.
- **hint_fwd_pd** – Primitive descriptor for an LBR GRU forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_layer_desc**() const

Returns source layer memory descriptor.

Returns Source layer memory descriptor.

memory::desc **src_iter_desc**() const

Returns source iteration memory descriptor.

Returns Source iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source iteration parameter.

memory::desc **weights_layer_desc**() const

Returns weights layer memory descriptor.

Returns Weights layer memory descriptor.

memory::desc **weights_iter_desc**() const

Returns weights iteration memory descriptor.

Returns Weights iteration memory descriptor.

memory::desc **bias_desc**() const

Returns bias memory descriptor.

Returns Bias memory descriptor.

Returns A zero memory descriptor if the primitive does not have a bias parameter.

memory::desc **dst_layer_desc**() const

Returns destination layer memory descriptor.

Returns Destination layer memory descriptor.

memory::desc **dst_iter_desc**() const

Returns destination iteration memory descriptor.

Returns Destination iteration memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination iteration parameter.

memory::desc **workspace_desc()** const
Returns the workspace memory descriptor.
Returns Workspace memory descriptor.
Returns A zero memory descriptor if the primitive does not require workspace parameter.

memory::desc **diff_src_layer_desc()** const
Returns diff source layer memory descriptor.
Returns Diff source layer memory descriptor.

memory::desc **diff_src_iter_desc()** const
Returns diff source iteration memory descriptor.
Returns Diff source iteration memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff source iteration parameter.

memory::desc **diff_weights_layer_desc()** const
Returns diff weights layer memory descriptor.
Returns Diff weights layer memory descriptor.

memory::desc **diff_weights_iter_desc()** const
Returns diff weights iteration memory descriptor.
Returns Diff weights iteration memory descriptor.

memory::desc **diff_bias_desc()** const
Returns diff bias memory descriptor.
Returns Diff bias memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff bias parameter.

memory::desc **diff_dst_layer_desc()** const
Returns diff destination layer memory descriptor.
Returns Diff destination layer memory descriptor.

memory::desc **diff_dst_iter_desc()** const
Returns diff destination iteration memory descriptor.
Returns Diff destination iteration memory descriptor.
Returns A zero memory descriptor if the primitive does not have a diff destination iteration parameter.

algorithm **get_cell_kind()** const
Returns an RNN cell kind parameter.
Returns An RNN cell kind parameter.
Returns *dnnl::algorithm::undef* if the primitive does not have an RNN cell kind parameter.

prop_kind **get_prop_kind()** const
Returns a propagation kind.
Returns A propagation kind.
Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

rnn_direction **get_direction()** const
Returns an RNN direction parameter.
Returns An RNN direction parameter.
Returns *dnnl::rnn_direction::undef* if the primitive does not have an RNN direction parameter.

5.5.18 Shuffle

The shuffle primitive shuffles data along the shuffle axis (here is designated as C) with the group parameter G . Namely, the shuffle axis is thought to be a 2D tensor of size $(\frac{C}{G} \times G)$ and it is being transposed to $(G \times \frac{C}{G})$. Variable names follow the standard *Conventions*.

The formal definition is shown below:

Forward

$$\text{dst}(\overline{ou}, c, \overline{in}) = \text{src}(\overline{ou}, c', \overline{in})$$

where

- c dimension is called a shuffle axis,
- G is a `group_size`,
- \overline{ou} is the outermost indices (to the left from shuffle axis),
- \overline{in} is the innermost indices (to the right from shuffle axis), and
- c' and c relate to each other as define by the system:

$$\begin{cases} c &= u + v \cdot \frac{C}{G}, \\ c' &= u \cdot G + v, \end{cases}$$

Here, $0 \leq u < \frac{C}{G}$ and $0 \leq v < G$.

Difference Between Forward Training and Forward Inference

There is no difference between the *forward_training* and *forward_inference* propagation kinds.

Backward

The backward propagation computes $\text{diff_src}(ou, c, in)$, based on $\text{diff_dst}(ou, c, in)$.

Essentially, backward propagation is the same as forward propagation with g replaced by C/g .

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_SRC</i>
dst	<i>DNNL_ARG_DST</i>
diff_src	<i>DNNL_ARG_DIFF_SRC</i>
diff_dst	<i>DNNL_ARG_DIFF_DST</i>

Operation Details

Data Types Support

The shuffle primitive supports the following combinations of data types:

Note: Here we abbreviate data types names for readability. For example, `dnnl::memory::data_type::f32` is abbreviated to `f32`.

Propagation	Source / Destination
forward / backward	<code>f32, bf16</code>
forward	<code>s32, s8, u8</code>

Data Layouts

The shuffle primitive works with arbitrary data tensors. There is no special meaning associated with any logical dimensions. However, the shuffle axis is typically referred to as channels (hence in formulas we use `c`).

Shuffle operation typically appear in CNN topologies. Hence, in the library the shuffle primitive is optimized for the corresponding memory formats:

Spatial	Logical tensor	Shuffle Axis	Implementations optimized for memory formats
2D	NCHW	1 (C)	<code>nchw (abcd), nhwc (acdb), optimized^</code>
3D	NCDHW	1 (C)	<code>ncdhw (abcde), ndhwc (acdeb), optimized^</code>

Here `optimized^` means the format that comes out of any preceding compute-intensive primitive.

Post-ops and Attributes

The shuffle primitive does not have to support any post-ops or attributes.

API

```
struct dnnl::shuffle_forward : public dnnl::primitive
    Shuffle forward propagation primitive.
```

Public Functions

```
shuffle_forward()
```

Default constructor. Produces an empty object.

```
shuffle_forward(const primitive_desc &pd)
```

Constructs a shuffle forward propagation primitive.

Parameters `pd` – Primitive descriptor for a shuffle forward propagation primitive.

```
struct primitive_desc : public dnnl::primitive_desc
```

Primitive descriptor for a shuffle forward propagation primitive.

Public Functions

primitive_desc() = default

Default constructor. Produces an empty object.

primitive_desc(const *engine* &aengine, *prop_kind* aprop_kind, const *memory::desc* &src_desc, const *memory::desc* &dst_desc, int axis, int group_size, const *primitive_attr* &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a shuffle forward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprof_kind** – Propagation kind. Possible values are *dnnl::prop_kind::forward_training*, and *dnnl::prop_kind::forward_inference*.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **axis** – The axis along which the data is shuffled.
- **group_size** – Shuffle group size.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

memory::desc **src_desc()** const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

memory::desc **dst_desc()** const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

prop_kind **get_prop_kind()** const

Returns a propagation kind.

Returns A propagation kind.

Returns *dnnl::prop_kind::undef* if the primitive does not have a propagation parameter.

int **get_axis()** const

Returns an axis.

Returns An axis.

Returns A negative number if the primitive does not have an axis parameter.

memory::dim **get_group_size()** const

Returns a shuffle group size parameter.

Returns A shuffle group size parameter.

Returns Zero if the primitive does not have a shuffle group size parameter.

struct *dnnl::shuffle_backward* : public *dnnl::primitive*

Shuffle backward propagation primitive.

Public Functions

`shuffle_backward()`

Default constructor. Produces an empty object.

`shuffle_backward(const primitive_desc &pd)`

Constructs a shuffle backward propagation primitive.

Parameters `pd` – Primitive descriptor for a shuffle backward propagation primitive.

struct `primitive_desc` : public `dnnl::primitive_desc`

Primitive descriptor for a shuffle backward propagation primitive.

Public Functions

`primitive_desc()` = default

Default constructor. Produces an empty object.

`primitive_desc`(const `engine` &engine, const `memory::desc` &diff_src_desc, const `memory::desc` &diff_dst_desc, int axis, int group_size, const `shuffle_forward::primitive_desc` &hint_fwd_pd, const `primitive_attr` &attr = default_attr(), bool allow_empty = false)

Constructs a primitive descriptor for a shuffle backward propagation primitive.

Parameters

- `aengine` – Engine to use.
- `diff_src_desc` – Diff source memory descriptor.
- `diff_dst_desc` – Diff destination memory descriptor.
- `axis` – The axis along which the data is shuffled.
- `group_size` – Shuffle group size.
- `hint_fwd_pd` – Primitive descriptor for a shuffle forward propagation primitive. It is used as a hint for deciding which memory format to use.
- `attr` – Primitive attributes to use. Attributes are optional and default to empty attributes.
- `allow_empty` – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc diff_src_desc()` const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

`memory::desc diff_dst_desc()` const

Returns a diff destination memory descriptor.

Returns Diff destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff destination parameter.

`prop_kind get_prop_kind()` const

Returns a propagation kind.

Returns A propagation kind.

Returns `dnnl::prop_kind::undef` if the primitive does not have a propagation parameter.

int `get_axis()` const

Returns an axis.

Returns An axis.

Returns A negative number if the primitive does not have an axis parameter.

`memory::dim get_group_size()` const

Returns a shuffle group size parameter.

Returns A shuffle group size parameter.

Returns Zero if the primitive does not have a shuffle group size parameter.

5.5.19 Softmax

The softmax primitive performs softmax along a particular axis on data with arbitrary dimensions. All other axes are treated as independent (batch).

In general form, the operation is defined by the following formulas. The variable names follow the standard *Conventions*.

Forward

When the specified algorithm is softmax:

$$\text{dst}(\overline{ou}, c, \overline{in}) = \frac{e^{\text{src}(\overline{ou}, c, \overline{in}) - \nu(\overline{ou}, \overline{in})}}{\sum_{ic} e^{\text{src}(\overline{ou}, ic, \overline{in}) - \nu(\overline{ou}, \overline{in})}}.$$

When the specified algorithm is logsoftmax, the following numerically stable formula is used:

$$\text{dst}(\overline{ou}, c, \overline{in}) = \ln \left(\frac{e^{\text{src}(\overline{ou}, c, \overline{in}) - \nu(\overline{ou}, \overline{in})}}{\sum_{ic} e^{\text{src}(\overline{ou}, ic, \overline{in}) - \nu(\overline{ou}, \overline{in})}} \right) = (\text{src}(\overline{ou}, c, \overline{in}) - \nu(\overline{ou}, \overline{in})) - \ln \left(\sum_{ic} e^{\text{src}(\overline{ou}, ic, \overline{in}) - \nu(\overline{ou}, \overline{in})} \right)$$

where

- c axis over which the softmax computation is computed on,
- \overline{ou} is the outermost index (to the left of softmax axis),
- \overline{in} is the innermost index (to the right of softmax axis), and
- ν is used to produce more accurate results and defined as:

$$\nu(\overline{ou}, \overline{in}) = \max_{ic} \text{src}(\overline{ou}, ic, \overline{in})$$

Difference Between Forward Training and Forward Inference

There is no difference between the *forward_training* and *forward_inference* propagation kinds.

Backward

The backward propagation computes $\text{diff_src}(ou, c, in)$, based on $\text{diff_dst}(ou, c, in)$ and $\text{dst}(ou, c, in)$.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

Primitive input/output	Execution argument index
src	<i>DNNL_ARG_SRC</i>
dst	<i>DNNL_ARG_DST</i>
diff_src	<i>DNNL_ARG_DIFF_SRC</i>
diff_dst	<i>DNNL_ARG_DIFF_DST</i>

Operation Details

- Both forward and backward propagation support in-place operations, meaning that `src` can be used as input and output for forward propagation, and `diff_dst` can be used as input and output for backward propagation. In case of in-place operation, the original data will be overwritten.

Post-ops and Attributes

The softmax primitive does not have to support any post-ops or attributes.

Data Types Support

The softmax primitive supports the following combinations of data types.

Note: Here we abbreviate data types names for readability. For example, *dnnl::memory::data_type::f32* is abbreviated to *f32*.

Propagation	Source / Destination
forward / backward	<i>bf16, f32</i>
forward	<i>f16</i>

Data Representation

Source, Destination, and Their Gradients

The softmax primitive works with arbitrary data tensors. There is no special meaning associated with any logical dimensions. However, the softmax axis is typically referred to as channels (hence in formulas we use c).

API

struct `dnnl::softmax_forward` : public `dnnl::primitive`
 Softmax forward propagation primitive.

Public Functions

`softmax_forward()`

Default constructor. Produces an empty object.

`softmax_forward(const primitive_desc &pd)`

Constructs a softmax forward propagation primitive.

Parameters `pd` – Primitive descriptor for a softmax forward propagation primitive.

struct `primitive_desc` : public `dnnl::primitive_desc`
 Primitive descriptor for a softmax forward propagation primitive.

Public Functions

`primitive_desc()` = default

Default constructor. Produces an empty object.

`primitive_desc(const engine &aengine, prop_kind aprop_kind, algorithm aalgorithm, const memory::desc &src_desc, const memory::desc &dst_desc, int axis, const primitive_attr &attr = default_attr(), bool allow_empty = false)`

Constructs a primitive descriptor for a softmax forward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aprop_kind** – Propagation kind. Possible values are `dnnl::prop_kind::forward_training`, and `dnnl::prop_kind::forward_inference`.
- **aalgorithm** – Softmax algorithm kind: either `dnnl::algorithm::softmax_accurate`, or `dnnl::algorithm::softmax_log`.
- **src_desc** – Source memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **axis** – Axis over which softmax is computed.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc src_desc()` const

Returns a source memory descriptor.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter.

`memory::desc dst_desc()` const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

`dnnl::algorithm get_algorithm()` const

Returns an algorithm kind.

Returns An algorithm kind.

Returns `dnnl::algorithm::undef` if the primitive does not have an algorithm parameter.

`dnnl::prop_kind get_prop_kind()` const

Returns a propagation kind.

Returns A propagation kind.

Returns `dnnl::prop_kind::undef` if the primitive does not have a propagation parameter.

`int get_axis()` const

Returns an axis.

Returns An axis.

Returns A negative number if the primitive does not have an axis parameter.

struct `dnnl::softmax_backward` : public `dnnl::primitive`

Softmax backward propagation primitive.

Public Functions

`softmax_backward()`

Default constructor. Produces an empty object.

`softmax_backward(const primitive_desc &pd)`

Constructs a softmax backward propagation primitive.

Parameters `pd` – Primitive descriptor for a softmax backward propagation primitive.

struct `primitive_desc` : public `dnnl::primitive_desc`

Primitive descriptor for a softmax backward propagation primitive.

Public Functions

`primitive_desc()` = default

Default constructor. Produces an empty object.

`primitive_desc(const engine &aengine, algorithm aalgorithm, const memory::desc &diff_src_desc, const memory::desc &diff_dst_desc, const memory::desc &dst_desc, int axis, const softmax_forward::primitive_desc &hint_fwd_pd, const primitive_attr &attr = default_attr(), bool allow_empty = false)`

Constructs a primitive descriptor for a softmax backward propagation primitive.

Parameters

- **aengine** – Engine to use.
- **aalgorithm** – Softmax algorithm kind: either `dnnl::algorithm::softmax_accurate`, or `dnnl::algorithm::softmax_log`.
- **diff_src_desc** – Diff source memory descriptor.
- **diff_dst_desc** – Diff destination memory descriptor.
- **dst_desc** – Destination memory descriptor.
- **axis** – Axis over which softmax is computed.
- **hint_fwd_pd** – Primitive descriptor for a softmax forward propagation primitive. It is used as a hint for deciding which memory format to use.
- **attr** – Primitive attributes to use. Attributes are optional and default to empty attributes.
- **allow_empty** – A flag signifying whether construction is allowed to fail without throwing an exception. In this case an empty object will be produced. This flag is optional and defaults to false.

`memory::desc dst_desc()` const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

`memory::desc diff_src_desc()` const

Returns a diff source memory descriptor.

Returns Diff source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a diff source memory with.

`memory::desc diff_dst_desc()` const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

`dnnl::algorithm get_algorithm()` const

Returns an algorithm kind.

Returns An algorithm kind.

Returns `dnnl::algorithm::undef` if the primitive does not have an algorithm parameter.

`dnnl::prop_kind get_prop_kind()` const

Returns a propagation kind.

Returns A propagation kind.

Returns `dnnl::prop_kind::undef` if the primitive does not have a propagation parameter.

`int get_axis()` const

Returns an axis.

Returns An axis.

Returns A negative number if the primitive does not have an axis parameter.

5.5.20 Sum

The sum primitive sums N tensors. The variable names follow the standard *Conventions*.

$$\text{dst}(\bar{x}) = \sum_{i=1}^N \text{scales}(i) \cdot \text{src}_i(\bar{x})$$

The sum primitive does not have a notion of forward or backward propagations. The backward propagation for the sum operation is simply an identity operation.

Execution Arguments

When executed, the inputs and outputs should be mapped to an execution argument index as specified by the following table.

primitive input/output	execution argument index
src	<code>DNNL_ARG_MULTIPLE_SRC</code>
dst	<code>DNNL_ARG_DST</code>

Operation Details

- The dst memory format can be either specified by a user or derived the most appropriate one by the primitive. The recommended way is to allow the primitive to choose the appropriate format.
- The sum primitive requires all source and destination tensors to have the same shape. Implicit broadcasting is not supported.

Post-ops and Attributes

The sum primitive does not support any post-ops or attributes.

Data Types Support

The sum primitive supports arbitrary data types for source and destination tensors.

Data Representation

Sources, Destination

The sum primitive works with arbitrary data tensors. There is no special meaning associated with any logical dimensions.

API

```
struct dnnl::sum : public dnnl::primitive
    Out-of-place summation (sum) primitive.
```

Public Functions

```
sum()
    Default constructor. Produces an empty object.
```

```
sum(const primitive_desc &pd)
    Constructs a sum primitive.
```

Parameters **pd** – Primitive descriptor for sum primitive.

```
struct primitive_desc : public dnnl::primitive_desc_base
    Primitive descriptor for a sum primitive.
```

Public Functions

```
primitive_desc()
    Default constructor. Produces an empty object.
```

```
primitive_desc(const memory::desc &dst, const std::vector<float> &scales, const
               std::vector<memory::desc> &srcs, const engine &aengine, const primitive_attr &attr
               = primitive_attr())
```

Constructs a primitive descriptor for a sum primitive.

Parameters

- **dst** – Destination memory descriptor.
- **scales** – Vector of scales to multiply data in each source memory by.
- **srcs** – Vector of source memory descriptors.
- **aengine** – Engine to perform the operation on.
- **attr** – Primitive attributes to use (optional).

primitive_desc(const std::vector<float> &scales, const std::vector<memory::desc> &srcs, const engine &aengine, const primitive_attr &attr = primitive_attr())

Constructs a primitive descriptor for a sum primitive.

This version derives the destination memory descriptor automatically.

Parameters

- **scales** – Vector of scales by which to multiply data in each source memory object.
- **srcs** – Vector of source memory descriptors.
- **aengine** – Engine on which to perform the operation.
- **attr** – Primitive attributes to use (optional).

memory::desc **src_desc**(int idx = 0) const

Returns a source memory descriptor.

Parameters **idx** – Source index.

Returns Source memory descriptor.

Returns A zero memory descriptor if the primitive does not have a source parameter with index idx.

memory::desc **dst_desc**() const

Returns a destination memory descriptor.

Returns Destination memory descriptor.

Returns A zero memory descriptor if the primitive does not have a destination parameter.

5.6 Graph extension

oneDNN Graph extension is a flexible graph interface to maximize operation fusions in a scalable way. oneDNN Graph API accepts a full computational graph as input and performs an engine-aware graph partitioning, where sub-graphs of operations that are candidate for fusion are grouped together. Those partitions are then compiled and executed as fused operations.

5.6.1 Common Definitions

This section lists common types and definitions used by all or multiple graph operations.

Logical tensor enums and type

```
struct dnnl::graph::logical_tensor
```

Logical tensor object.

Public Types

```
enum class data_type
```

Data Type.

Values:

```
enumerator undef
```

```
enumerator f16
```

16-bit/half-precision floating point.

enumerator **bf16**
non-standard 16-bit (bfloat16 w/ 7 bit mantissa) floating point.

enumerator **f32**
32-bit/single-precision floating point.

enumerator **s32**
32-bit signed integer.

enumerator **s8**
8-bit signed integer.

enumerator **u8**
8-bit unsigned integer.

enum class **layout_type**
Layout type.

Values:

enumerator **undef**
Undefined layout type.

enumerator **any**
Any means to let the library to decide the layout for a tensor during partition compilation.

enumerator **strided**
Strided means that the layout of a tensor is determined by the strides field in the logical tensor.

enumerator **opaque**
Opaque means that the layout of a tensor is the library specific. Usually, an opaque layout is generated by a partition which is compiled with layout type any.

enum class **property_type**
Tensor property.

Values:

enumerator **undef**
Undefined tensor property.

enumerator **variable**
Variable means the tensor may be changed during computation or between different iterations.

enumerator **constant**
Constant means the tensor will keep unchanged during computation and between different iterations. It's useful for the library to apply optimizations for constant tensors or cache constant tensors inside the library. For example, constant weight tensors in inference scenarios.

Public Functions

logical_tensor() = default

Default constructor Construct an empty object

logical_tensor(const *logical_tensor* &other) = default

Copy constructor.

logical_tensor &**operator**=(const *logical_tensor* &other) = default

Assignment operator.

logical_tensor(size_t tid, *data_type* dtype, int32_t ndims, *layout_type* ltype, *property_type* ptype = *property_type::undef*)

Constructs a logical tensor object with ID, data type, ndims, layout type, and property type.

Parameters

- **tid** – Logical tensor ID.
- **dtype** – Elements data type.
- **ndims** – Number of dimensions. *DNNL_GRAPH_UNKNOWN_NDIMS* for an unknown number of dimensions, 0 for a scalar tensor.
- **ltype** – Layout type.
- **ptype** – Property type.

inline **logical_tensor**(size_t tid, *data_type* dtype, *layout_type* ltype = *layout_type::undef*)

Delegated constructor.

Parameters

- **tid** – Logical tensor ID.
- **dtype** – Elements data type.
- **ltype** – Layout type.

logical_tensor(size_t tid, *data_type* dtype, const dims &adims, *layout_type* ltype, *property_type* ptype = *property_type::undef*)

Constructs a logical tensor object with basic information and detailed dims.

Parameters

- **tid** – Logical tensor ID.
- **dtype** – Elements data type.
- **adims** – Logical tensor dimensions. *DNNL_GRAPH_UNKNOWN_DIM* for dimensions of unknown size, 0 for zero-dimension tensor.
- **ltype** – Layout type. If strided, the strides field in the output logical tensor will be deduced accordingly.
- **ptype** – Property type.

logical_tensor(size_t tid, *data_type* dtype, const dims &adims, const dims &strides, *property_type* ptype = *property_type::undef*)

Constructs a logical tensor object with detailed dims and strides. The *layout_type* of the output logical tensor object will always be strided.

Parameters

- **tid** – Logical tensor ID.

- **dtype** – Elements data type.
- **adims** – Logical tensor dimensions. *DNNL_GRAPH_UNKNOWN_DIM* for dimensions of unknown size, 0 for zero-dimension tensor.
- **strides** – Logical tensor strides. *DNNL_GRAPH_UNKNOWN_DIM* for unknown stride. No negative stride is supported.
- **pctype** – Property type.

logical_tensor(size_t tid, *data_type* dtype, const dims &adims, size_t lid, *property_type* pctype = *property_type::undef*)

Constructs a logical tensor object with detailed dims and an opaque layout ID. layout_type of the output logical tensor object will always be opaque.

Parameters

- **tid** – Logical tensor ID.
- **dtype** – Elements data type.
- **adims** – Logical tensor dimensions. *DNNL_GRAPH_UNKNOWN_DIM* for dimensions of unknown size, 0 for zero-dimension tensor.
- **lid** – Opaque layout id.
- **pctype** – Property type

dims **get_dims**() const

Returns the dimensions of a logical tensor.

Returns A vector describing the size of each dimension.

size_t **get_id**() const

Returns the unique id of a logical tensor.

Returns An integer value describing the ID.

data_type **get_data_type**()

Returns the data type of a logical tensor.

Returns The data type.

property_type **get_property_type**() const

Returns the property type of a logical tensor.

Returns The property type.

layout_type **get_layout_type**() const

Returns the layout type of a logical tensor.

Returns The layout type.

size_t **get_layout_id**() const

Returns the layout ID of a logical tensor. The API should be called on a logical tensor with opaque layout type. Otherwise, an exception will be raised.

Returns Layout ID.

dims **get_strides**() const

Returns the strides of a logical tensor. The API should be called on a logical tensor with strided layout type. Otherwise, an exception will be raised.

Returns A vector describing the stride size of each dimension.

`size_t get_mem_size()` const

Returns memory size in bytes required by this logical tensor.

Returns The memory size in bytes.

bool `is_equal`(const *logical_tensor* <)

Compares if two logical tensors are equal. Users can decide accordingly if layout reordering is needed for two logical tensors. The method will return true for below two circumstances:

- i. the two logical tensors are equal regarding each field in the struct, eg. `id`, `ndims`, `dims`, layout type, property, etc.
- ii. If all other fields are equal but the layout types in two logical tensors are different, the method will return true when the underlying memory layout is the same. For example, one logical tensor has strided layout type while the other one has opaque layout type, but underneath, both layouts are NHWC, the method will still return true for this case.

Parameters `lt` – The input logical tensor to be compared.

Returns `true` if the two logical tensors are equal. `false` otherwise

Operation attributes and kinds

struct `dnnl::graph::op`

An op object.

Public Types

enum class `kind`

Kinds of operations.

Values:

enumerator `Abs`

enumerator `AbsBackward`

enumerator `Add`

enumerator `AvgPool`

enumerator `AvgPoolBackward`

enumerator `BatchNormForwardTraining`

enumerator `BatchNormInference`

enumerator `BatchNormTrainingBackward`

enumerator `BiasAdd`

enumerator `BiasAddBackward`

enumerator `Clamp`

enumerator `ClampBackward`

enumerator `Concat`

enumerator **Convolution**
enumerator **ConvolutionBackwardData**
enumerator **ConvolutionBackwardWeights**
enumerator **ConvTranspose**
enumerator **ConvTransposeBackwardData**
enumerator **ConvTransposeBackwardWeights**
enumerator **Dequantize**
enumerator **Divide**
enumerator **DynamicDequantize**
enumerator **DynamicQuantize**
enumerator **Elu**
enumerator **EluBackward**
enumerator **End**
enumerator **Exp**
enumerator **GELU**
enumerator **GELUBackward**
enumerator **HardSwish**
enumerator **HardSwishBackward**
enumerator **Interpolate**
enumerator **InterpolateBackward**
enumerator **LayerNorm**
enumerator **LayerNormBackward**
enumerator **LeakyReLU**
enumerator **Log**
enumerator **LogSoftmax**
enumerator **LogSoftmaxBackward**
enumerator **MatMul**
enumerator **Maximum**
enumerator **MaxPool**
enumerator **MaxPoolBackward**
enumerator **Minimum**
enumerator **Mish**
enumerator **MishBackward**
enumerator **Multiply**
enumerator **PReLU**
enumerator **PReLUBackward**

enumerator **Quantize**
enumerator **Reciprocal**
enumerator **ReduceL1**
enumerator **ReduceL2**
enumerator **ReduceMax**
enumerator **ReduceMean**
enumerator **ReduceMin**
enumerator **ReduceProd**
enumerator **ReduceSum**
enumerator **ReLU**
enumerator **ReLUBackward**
enumerator **Reorder**
enumerator **Round**
enumerator **Sigmoid**
enumerator **SigmoidBackward**
enumerator **SoftMax**
enumerator **SoftMaxBackward**
enumerator **SoftPlus**
enumerator **SoftPlusBackward**
enumerator **Sqrt**
enumerator **SqrtBackward**
enumerator **Square**
enumerator **SquaredDifference**
enumerator **StaticReshape**
enumerator **StaticTranspose**
enumerator **Subtract**
enumerator **Tanh**
enumerator **TanhBackward**
enumerator **TypeCast**
enumerator **Wildcard**
enumerator **LastSymbol**

enum class **attr**

Attributes of operations. Different operations support different attributes. Check the document of each operation for what attributes are supported and what are the potential values for them. Missing required attribute or illegal attribute value may lead to failure when adding the operation to a graph.

Values:

- enumerator **undef**
Undefined op attribute.
- enumerator **alpha**
Specifies an alpha attribute to an op.
- enumerator **beta**
Specifies an beta attribute to an op.
- enumerator **epsilon**
Specifies an epsilon attribute to an op.
- enumerator **max**
Specifies a max attribute to an op.
- enumerator **min**
Specifies a min attribute to an op.
- enumerator **momentum**
Specifies a momentum attribute to an op.
- enumerator **scales**
Specifies a scales attribute to an op.
- enumerator **axis**
Specifies an axis attribute to an op.
- enumerator **begin_norm_axis**
Specifies a begin_norm_axis attribute to an op.
- enumerator **groups**
Specifies a groups attribute to an op.
- enumerator **axes**
Specifies an axes attribute to an op.
- enumerator **dilations**
Specifies a dilations attribute to an op.
- enumerator **dst_shape**
Specifies an dst_shape attribute to an op.
- enumerator **kernel**
Specifies a kernel attribute to an op.
- enumerator **order**
Specifies an order attribute to an op.
- enumerator **output_padding**
Specifies an output_padding attribute to an op.

- enumerator **pads_begin**
Specifies a pads_begin attribute to an op.
- enumerator **pads_end**
Specifies a pads_end attribute to an op.
- enumerator **shape**
Specifies a shape attribute to an op.
- enumerator **sizes**
Specifies a sizes attribute to an op.
- enumerator **src_shape**
Specifies an src_shape attribute to an op.
- enumerator **strides**
Specifies a strides attribute to an op.
- enumerator **weights_shape**
Specifies a weight_shape attribute to an op.
- enumerator **zps**
Specifies a zps attribute to an op.
- enumerator **exclude_pad**
Specifies an exclude_pad attribute to an op.
- enumerator **keep_dims**
Specifies a keep_dims attribute to an op.
- enumerator **keep_stats**
Specifies a keep_stats attribute to an op.
- enumerator **per_channel_broadcast**
Specifies a per_channel_broadcast attribute to an op.
- enumerator **special_zero**
Specifies a special_zero attribute to an op.
- enumerator **transpose_a**
Specifies a transpose_a attribute to an op.
- enumerator **transpose_b**
Specifies a transpose_b attribute to an op.
- enumerator **use_affine**
Specifies an use_affine attribute to an op.
- enumerator **use_dst**
Specifies an use_dst attribute to an op.

enumerator **auto_broadcast**

Specifies an `auto_broadcast` attribute to an op. The value can be “none” or “numpy”.

enumerator **auto_pad**

Specifies an `auto_pad` attribute to an op. The value can be “none”, “same_upper”, “same_lower”, or “valid”.

enumerator **coordinate_transformation_mode**

Specifies an `coordinate_transformation_mode` attribute to an op. The value can be “half_pixel” or “align_corners”. The attribute is defined for Interpolate operations.

enumerator **data_format**

Specifies a `data_format` of an op. The value can be “NCX” or “NXC”.

enumerator **mode**

Specifies a `mode` attribute of an op. The value can be “nearest”, “linear”, “bilinear”, or “trilinear”. The attribute is defined for Interpolate operations.

enumerator **qtype**

Specifies a `qtype` attribute to an op. The value can be “per_channel” or “per_tensor”. The attribute is defined for quantization operations.

enumerator **rounding_type**

Specifies a `rounding_type` attribute to an op. The value can be “ceil” or “floor”.

enumerator **weights_format**

Specifies a `weights_format` of an op. The value can be “OIX”, “XIO”, “IOX”, or “XOI”. Different operations may support different values.

Public Functions

op(size_t id, *kind* akind, const std::string &name = "")

Constructs an op object with a unique ID, an operation kind, and a name string.

Parameters

- **id** – The unique ID of the op.
- **akind** – The op kind specifies which computation is represented by the op, such as Convolution or ReLU.
- **name** – The string added as the op name.

op(size_t id, *kind* akind, const std::vector<*logical_tensor*> &inputs, const std::vector<*logical_tensor*> &outputs, const std::string &name = "")

Constructs an op object with a unique ID, an operation kind, and input/output logical tensors.

Parameters

- **id** – The unique ID of this op.
- **akind** – The op kind specifies which computation is represented by this op, such as Convolution or ReLU.
- **inputs** – Input logical tensor to be bound to this op.
- **outputs** – Output logical tensor to be bound to this op.

- **name** – The string added as the op name.

void **add_input**(const *logical_tensor* &t)
Adds an input logical tensor to the op.

Parameters **t** – Input logical tensor.

void **add_inputs**(const std::vector<*logical_tensor*> &ts)
Adds a vector of input logical tensors to the op.

Parameters **ts** – The list of input logical tensors.

void **add_output**(const *logical_tensor* &t)
Adds an output logical tensor to the op.

Parameters **t** – Output logical tensor.

void **add_outputs**(const std::vector<*logical_tensor*> &ts)
Adds a vector of output logical tensors to the op.

Parameters **ts** – The list of output logical tensors.

template<typename **Type**>
op &**set_attr**(*attr* name, const *Type* &value)
Sets the attribute according to the name and type.

Template Parameters **Type** – Attribute's type.

Parameters

- **name** – Attribute's name.
- **value** – The attribute's value.

Returns The Op self. Raises an exception if Type is incompatible with name.

Graph objects member functions

struct dnnl::graph::**graph**
A graph object.

Public Functions

graph(dnnl::engine::kind engine_kind)
Constructs a graph with an engine kind.

Parameters **engine_kind** – Engine kind.

graph(dnnl::engine::kind engine_kind, dnnl::fpmath_mode mode)
Creates a new empty graph with an engine kind and a floating-point math mode. All partitions returned from the graph will inherit the engine kind and floating-point math mode.

Parameters

- **engine_kind** – Engine kind.
- **mode** – Floating-point math mode.

status **add_op**(const *op* &op, bool allow_exception = true)
Adds an op into the graph to construct a computational DAG. The API will return failure if the operator has already been added to the graph or the operation cannot pass the schema check in the library (eg. input and output numbers and data types, the attributes of the operation, etc.).

Parameters

- **op** – An operation to be added.
- **allow_exception** – A flag indicating whether the method is allowed to throw an exception if it fails to add the op to the graph.

Returns status::success or a status describing the error otherwise.

void **finalize()**

Finalizes a graph. It means users have finished adding operations into the graph and the graph is ready for partitioning. Adding a new operation into a finalized graph will return failures. Similarly, partitioning on a un-finalized graph will also return failures.

bool **is_finalized()** const

Checks if a graph is finalized.

Returns True if the graph is finalized or false if the graph is not finalized.

std::vector<partition> **get_partitions**(partition::policy policy = partition::policy::fusion)

Gets filtered partitions from a graph. Partitions will be claimed internally according to the capability of the library, the engine kind of the graph, and the policy.

Parameters **policy** – Partition policy, defaults to policy dnnl::graph::partition::policy::fusion.

Returns A vector storing the partitions.

Macros to specify unknown shapes**DNNL_GRAPH_UNKNOWN_NDIMS**

A wildcard value for number of dimensions which is unknown at a tensor or operation creation time.

DNNL_GRAPH_UNKNOWN_DIM

A wildcard value for dimensions that are unknown at a tensor or operation creation time.

5.6.2 Programming Model

oneDNN Graph programming model allows users to pass a computation graph and get partitions. Users then compile partitions, bind tensor data, and execute compiled partitions. Partitions are decided by the oneDNN Graph implementation, which allows a scalable (no change in user code to benefit from new fusion patterns) and platform aware partitioning.

The programming model assumes that the main usage is to support deep learning (DL) frameworks or inference engines. DL frameworks have their own representation for the computation graph. oneDNN Graph API is used to offload or accelerate graph partitions from a framework graph. In the description below, “graph” refers to the graph built by oneDNN Graph implementation, and “framework graph” refers to the graph built by the DL framework.

A deep learning computation graph consists of deep neural network (DNN) operations. A DNN operation is a function that takes input data and returns output data. The input and output data are multidimensional arrays called tensors. A DNN operation may consume multiple tensors and produce multiple tensors. A tensor must be produced by a single operation and may be consumed by multiple operations.

oneDNN Graph API uses logical tensor, OP, and graph to represent a computation graph. Logical tensor represents tensor’s metadata, like element data type, shape, and layout. OP represents an operation on a computation graph. OP has kind, attribute, and input and output logical tensors. OPs are added to a graph. Both OP and logical tensor contains a unique ID, so that the graph knows how to connect a producer OP to a consumer OP through a logical tensor. The graph constructed is immutable. The purpose of creating the graph object is to get partitions. After partitions are created, the graph object is not useful anymore. Once users get partitions, users should not add OP to the graph.

oneDNN Graph defines operation set. Users should convert their DNN operation definition to oneDNN Graph operation for graph construction. For operation outside oneDNN Graph operation set, users may use wild-card OP. The wild-card OP represents any OP. With its input and output logical tensors, it enables the oneDNN Graph implementation to receive a full graph and conduct a complete analysis. User needs to use a special “End” op to indicate output tensors of the graph. For any tensors needs to be alive after a graph being executed, it needs to be connected to a “End” op which consumes the tensor. Users may have multiple “End” ops for one graph. For each OP users add to the graph, users must describe its input and output logical tensors. Users must describe data type for each logical tensor. If tensor’s shape and layout are known, users must describe them along with the logical tensor.

A partition is a connected subgraph in a graph. oneDNN Graph implementation analyzes a graph and returns a number of partitions. The returned partitions completely cover all the OPs of the graph and follow topological order. A partition typically contains multiple Ops. Sometimes a partition may contain just one OP, like a Wildcard OP or unsupported OP. A partition contains a flag to indicate whether the partition is supported and thus can be compiled and executed. User needs to check the flag before using the partition.

Partition’s input and output is also called as port. The ports record the logical tensor information which was passed during graph construction. With the logical tensor ID, users can track the producer and consumer relationship between partitions. The ports also record the data type of corresponding logical tensors.

The returned partitions to users must not form a dependence cycle. For example, a graph contains 3 OPs: A, B, and C. If C consumes A’s output and produces B’s input, oneDNN Graph implementation must not put A and B into one partition. However, if C is not added to the graph, the returned partition may include A and B, since C is not visible to oneDNN Graph implementation. In this case, it is the user’s responsibility to detect the dependence cycle. Once users pass a complete graph, users don’t need to check the dependence cycle among the partitions returned by oneDNN Graph.

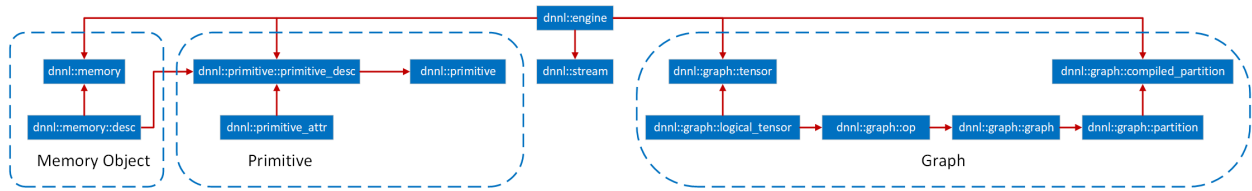

A partition needs to be compiled before execution. The compilation lowers down the compute logic to hardware ISA level and generates binary code. The generated code is specialized for the input and output tensor’s metadata. Users must create new logical tensors to pass complete metadata with the compilation API. The logical tensors should fully specify id, data type, shape (can be incomplete for outputs), and layout, the compilation should succeed. The logical tensors passed during compilation time must match IDs with partition’s ports. The logical tensors must have same data types with the ports with the port of the same ID.

For the output logical tensors, users must either specify a public layout using size and stride for each tensor dimension or request oneDNN Graph implementation to decide a target-specific layout. For the input logical tensors, users must either specify a public layout or using a target-specific layout produced by predecessor partition compilation. For the logical tensor with target-specific layout, it must be produced by a partition and used only by partitions.

A compiled partition represents the generated code specialized for target hardware and tensor metadata passed with compilation API. Users may cache the compiled partition to amortize the compilation cost among many iterations. If tensor metadata is identical, a compiled partition generated in previous iterations may be reused. Alternatively, implementations may reduce the partition compilation cost by caching the compiled partition internally. This optimization falls outside of the scope of this specification.

To execute a compiled partition, users must pass input and output tensors. Input tensors must bind input data buffers to logical tensors. Users may query the compiled partition for output data buffer sizes. If the sizes are known, users may allocate the output data buffers and bind to output tensors. If the sizes are unknown, users must provide an allocator for oneDNN Graph implementation to allocate the output tensor buffer. The execution API takes a compiled partition, input tensors, and return output tensors with the data buffer updated.

An engine represents a target device and context in the system. It needs to be passed as a parameter for partition compilation. A stream abstracts hardware execution resources of a target device. It is required to execute a compiled partition.

The diagram above summarizes the key programming concepts, and how they interact with each other. The arrow indicates the destination object contains or uses the source object. For example, OP contains logical tensor, and compiled partition uses partition.

Logical Tensor

Logical tensor describes the metadata of the input or output tensor, like element data type, number of dimensions, size for each dimension, layout.

Besides helping oneDNN Graph implementation to build the graph, Logical tensor plays a critical role to exchange tensor metadata information between users and oneDNN Graph implementation. Users pass input tensor shape information and get the inferred shape for output tensors from a partition. Users pass logical tensors to compilation API for specifying shape and layout information. Users also use a special logical tensor to allow oneDNN Graph implementation to decide the layout for output tensors. After compilation, users can query the compiled partition for output tensors' shape, layout, and sizes.

Each logical tensor has an ID. The tensor metadata may include new shape information in the framework graph as it progresses toward execution. As a logical tensor is not mutable, users must create a new logical tensor with the same ID to pass any new additional information to oneDNN Graph implementation. Users should guarantee that the logical tensor ID is unique within the graph which the logical tensor belongs to.

Operations

An operation (or *OP*) describes a deep neural network operation. OP contains kind, attribute, and input and output logical tensor shapes and properties. In particular, activation and weights tensor formats are specified as attributes to the operation.

Each operation has a unique ID and users should guarantee that uniqueness within the graph which the OP is added to.

Graph

Graph contains a set of OPs. `dnnl::graph::graph::add_op()` adds an OP and its logical tensors to a graph. oneDNN Graph implementation accumulates the OPs and logical tensors and constructs and validates the graph as internal state. During `dnnl::graph::graph::add_op()`, the target OP will be validated against its schema. Once the validation fails, an exception will be thrown out from the API. When `allow_exception=false` is specified, `dnnl::graph::graph::add_op()` call returns a status. It is the user's responsibility to handle the error either by checking the return value of the API or handling the exception.

A same logical tensor may appear more than twice in `dnnl::graph::graph::add_op()` call, since it is passed with the producer OP and consumer OPs. oneDNN Graph validates logical tensors with the same id should be identical at the graph construction time.

Once the graph is fully described, `dnnl::graph::graph::finalize()` should be called. This prevents any other operation from being added, and allows to call `dnnl::graph::graph::get_partitions()` in order to get the set of partitions for that graph. The graph doesn't hold any meaning to the user after partitioning and should be freed by the user.

All the OPs added to the graph will be contained in one of the returned partitions. If an OP is not supported by the oneDNN Graph API implementation, the corresponding partition will be marked as "not supported". Users can check

the supporting status of a partition via the `dnnl::graph::partition::is_supported`. Partitions should not form cyclic dependence within the graph. If user doesn't pass a complete graph, it is the user's responsibility to detect any dependence cycle between the partitions and operations not passing to oneDNN Graph implementation.

The logical tensor passed at the graph construction stage might contain incomplete information, for example, dimension and shape information are spatially known. Complete information is not required but helps the oneDNN Graph to form better partition decisions. Adding op to a graph is not thread-safe. Users must create a graph, add op, and get partition in the same thread.

Partition

Partition represents a collection of OPs identified by oneDNN Graph implementation as the basic unit for compilation and execution. It contains a list of OP, input ports, output ports, and a flag indicating whether the partition is supported. When a partition is created, it's assigned with an ID. oneDNN Graph implementation should guarantee the partition ID is globally unique.

Users can pass the output logical tensors with incomplete shape information (containing `DNNL_GRAPH_UNKNOWN_NDIMS` or `DNNL_GRAPH_UNKNOWN_DIM`) to partition compilation API. oneDNN Graph implementation needs calculate the output shapes according to the given input shapes and schema of the OP. After compilation finished, a compiled partition will be generated with full shape information for the input and output logical tensors. Users can query the compiled partition for the output logical tensors and get the shapes.

Partition can be compiled to generate a `compiled_partition`: an executable object to run the computation for that partition. Users must create an input logical tensor list and an output logical tensor list to pass the additional tensor metadata as parameters to the compilation API. The input and output logical tensors must match the id of partitions' ports, which captures the logical tensors information during graph partitioning. Typically, the more information is given before the partition step (e.g. number of dimensions and tensor dimensions), the most performant the code under the compiled partition will be.

Users must specify `strided`, `any`, or `opaque` as the `layout_type` for the parameter logical tensors. When users specify `any` for a logical tensor, the tensor must be an output tensor, and oneDNN Graph implementation decides the best performant layout for the compiled partition. If it is `strided`, it must use the public data layout described by the logical tensor. For `opaque`, the parameter logical tensor contains a target-specific layout, which must be determined by the compilation of preceding partitions producing the tensor. If the layout is row-major contiguous, the compilation must succeed. If the layout has a stride, it is implementation dependent whether the compilation succeed. If certain dimension of shape or the rank is unknown, it is implementation dependent whether the compilation succeed. If the compilation succeeds for unknown dimension or rank, the compiled partition should be able to handle any value for that dimension or any rank at the execution time.

Tensor

Tensor is an abstraction for multidimensional input and output data needed in the execution of a compiled partition. A tensor contains a logical tensor, an engine and a data handle.

Users are responsible for managing the tensor's lifecycle, e.g. free the resource allocated, when it is not used anymore.

Compiled Partition

A *compiled partition* represents the generated code specialized for target hardware and meta data described by parameter logical tensors. Compiled partition contains a partition and a handle representing the target specific compiled object.

After the compilation API is invoked, users must query the logical output tensor of the compiled partition to know the output tensor's layout id and size. The layout id is an opaque identifier for the target-specific layout. Users may pass the layout id for the next partition compilation so that it can be optimized to expect a specific input layout. Users may use the size to allocate the memory buffer of the output tensors for execution.

Framework passes the tensors and compiled partition as parameters to execution API. The parameter logical tensors must be in the same order when they are passed in the compilation API, and their IDs must match with the compiled partition's internal logical tensors. The layout type of each tensor must be `strided` or `opaque`.

The compiled partition may support in-place optimization, which reuses the input tensor data buffer for the output tensor for lower memory footprint and better data locality. For each compiled partition, users can get pairs of input and output ports. For the pair of input and output ports, user can use a same memory buffer when passing input and output tensors along with execution API. The in-place optimization is optional, when users use another memory buffer for the output tensor, oneDNN Graph must update the output tensor.

If users place a tensor with data buffer pointer in outputs, the backend shall use the data buffer provided by users.

Users may convert the parameter tensor with public layout to the target specific layout expected by the compiled partition. A common optimization in deep learning inference is that users may prepack the weight in the target-specific layout required by the compiled partition and cache the reordered weight for late use.

Engine

Engine (`dnnl::engine`) are an abstraction of a computational device. The graph extension additionally allows to create an engine with specific host/device allocators to conveniently manage memory inside the Graph API calls.

Stream

Stream (`dnnl::stream`) encapsulate execution context tied to a particular engine.

General API notes

There are certain assumptions on how oneDNN Graph objects behave:

- Logical tensor behave similarly to trivial types.
- All other objects behave like shared pointers. Copying is always shallow.

Error Handling

The C++ API throws exceptions for error handling.

5.6.3 Data Model

oneDNN Graph uses logical tensor to describe data type, shape, and layout. Besides 32-bit IEEE single-precision floating-point data type, oneDNN Graph can also support other data types. The shape contains multiple dimensions, and the total dimension and the size of the dimension could be set as unknown.

oneDNN Graph uses the following enumeration to refer to data types it supports. Different operation may support inputs and outputs with different data types, so it's suggested to refer to the definition page of each operation.

enum `dnnl::graph::logical_tensor::data_type`

undef Undefined data type (used for empty logical tensor).

f16 16-bit/half-precision floating point.

bf16 non-standard 16-bit floating point with 7-bit mantissa.

f32 32-bit/single-precision floating point.

s32 32-bit signed integer.

s8 8-bit signed integer.

u8 8-bit unsigned integer.

oneDNN Graph supports both public layout and *opaque* layout. When the *layout_type* of logical tensor is *strided*, it means that the tensor layout is public which the user can identify each tensor element in the physical memory.

For example, for $dims[] = x, y, z$, $strides[] = s_0, s_1, s_2$, the physical memory location should be in $s_0 * x + s_1 * y + s_2 * z$.

When the *layout_type* of logical tensor is *opaque*, users are not supposed to interpret the memory buffer directly. An *opaque* tensor can only be output from oneDNN Graph's compiled partition and can only be fed to another compile partition as an input tensor.

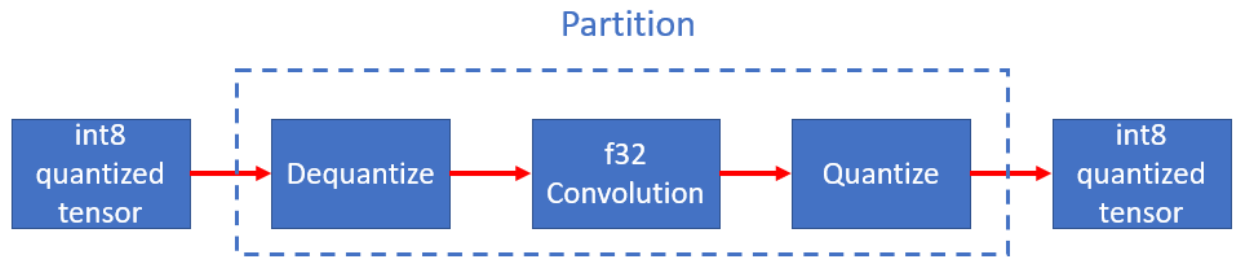

Low Precision Support

oneDNN Graph extension provides the same low precision support as the oneDNN primitives, including *u8*, *s8*, *bf16* and *f16*. For int8, oneDNN Graph API supports quantized model with static quantization. For bf16 or f16, oneDNN Graph supports deep learning framework's auto mixed precision mechanism. In both cases, oneDNN Graph API expects users to convert the computation graph to low precision representation and specify the data's precision and quantization parameters. oneDNN Graph API implementation should strictly respect the numeric precision of the computation.

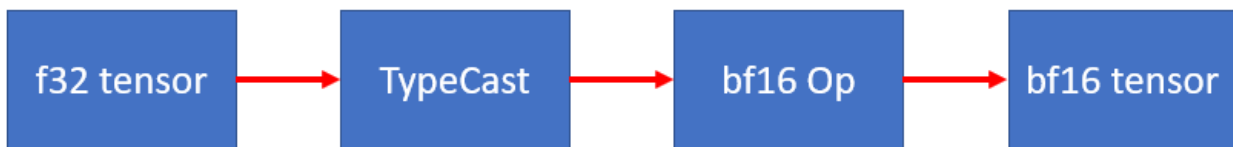

For int8, oneDNN Graph API provides two operations *dequantize* and *quantize*. Dequantize takes integer tensor with its associated scale and zero point and returns f32 tensor. Quantize takes an f32 tensor, scale, zero point, and returns an integer tensor. The scale and zero point are single dimension tensors, which could contain one value for the per-tensor quantization case or multiple values for the per-channel quantization case. The integer tensor could be represented in both unsigned int8 or signed int8. Zero point could be zero for symmetric quantization scheme, and a non-zero value for asymmetric quantization scheme.

Users should insert Dequantize and Quantize in the graph as part of quantization process before passing to oneDNN Graph. oneDNN Graph honors the data type passed from user and faithfully follows the data type semantics. For example, if the graph has a Quantize followed by Dequantize with exact same scale and zero point, oneDNN Graph implementation should not eliminate them since that implicitly changes the numerical precision.

oneDNN Graph partitioning API may return a partition containing the Dequantize, Quantize, and Convolution operations in between. Users don't need to recognize the subgraph pattern explicitly and convert to fused op. Depending on oneDNN Graph implementation capability, the partition may include more or fewer operations.

For bf16, oneDNN Graph provides the *typecast* operation, which can convert an f32 tensor to bf16 or f16, and vice versa. All oneDNN Graph operations support bf16 and f16. It is the user's responsibility to insert TypeCast to clearly indicate the numerical precision. oneDNN Graph implementation fully honors the user-specified numerical precision. If users first typecast from f32 to bf16 and convert back, oneDNN Graph implementation does the exact data type conversions underneath.

5.6.4 Operation Set

oneDNN Graph defines an operation set. oneDNN Graph implementation may support a subset of the operation set.

Abs

Abs operation performs element-wise the absolute value with given tensor, it applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$dst = \begin{cases} src & \text{if } src \geq 0 \\ -src & \text{if } src < 0 \end{cases}$$

Operation Attributes

Abs operation does not support any attribute.

Execution Arguments

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Abs operation supports the following data type combinations.

Src	Dst
f32	f32
f16	f16
bf16	bf16

AbsBackward

AbsBackward operation computes gradient for Abs operation.

$$\text{dst} = \begin{cases} \text{diff_dst} & \text{if } \text{src} > 0 \\ -\text{diff_dst} & \text{if } \text{src} < 0 \\ 0 & \text{if } \text{src} = 0 \end{cases}$$

Operation Attributes

AbsBackward operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

AbsBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

Add

Add operation performs element-wise addition operation with two given tensors applying multi-directional broadcast rules.

$$\text{dst}(\bar{x}) = \text{src}_0(\bar{x}) + \text{src}_1(\bar{x}).$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>auto_broadcast</i>	Specifies rules used for auto-broadcasting of src tensors	string	none, numpy, (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src_0	Required
1	src_1	Required

@note Both src shapes should match and no auto-broadcasting is allowed if *auto_broadcast* attributes is none. src_0 and src_1 shapes can be different and auto-broadcasting is allowed if *auto_broadcast* attributes is numpy.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Add operation supports the following data type combinations.

Source0/1	Destination
f32	f32
bf16	bf16
f16	f16

AvgPool

AvgPool operation performs the computation following the below formulas. Variable names follow the standard *Conventions*.

$$\text{dst}(n, c, oh, ow) = \frac{1}{DENOM} \sum_{kh, kw} \text{src}(n, c, oh \cdot SH + kh - PH_L, ow \cdot SW + kw - PW_L)$$

where,

- when attribute `exclude_pad` is set to false, in which case $DENOM = KH \cdot KW$,
- when attribute `exclude_pad` is set to true, in which case $DENOM$ equals to the size of overlap between an averaging window and images.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the window is moved	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>kernel</i>	Size of pooling window	s64	A s64 list containing positive values	Required
<i>exclude_pad</i>	Controls whether the padded values are counted	bool	True, False	required
<i>rounding_type</i>	Controls how to do rounding	string	floor (default), ceil	Optional
<i>auto_pad</i>	Controls how the paddings are calculated	string	none (default), same_upper, same_lower, valid	Optional
<i>data_format</i>	Controls how to interpret the shape of src and dst.	string	NCX, NXC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

AvgPool operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

AvgPoolBackward

AvgPoolBackward operation accepts diffdst tensor and srshape tensor (optional), and calculates diffsrc tensor.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the window is moved	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing n on-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing n on-negative values	Required
<i>kernel</i>	Size of pooling window	s64	A s64 list containing positive values	Required
<i>exclude_pad</i>	Controls whether the padded values are counted	bool	True, False	Required
<i>auto_pad</i>	Controls how the paddings are calculated	string	none (default), <i>same_upper</i> , <i>same_lower</i> , <i>valid</i>	Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX, NXC (default)	Optional
<i>src_shape</i>	Denotes the shape of input of forward op	string	NCX, NXC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	diff_dst	Required
1	src_shape	Optional

@note Either `src_shape` input or `src_shape` attribute should be provided. If both provided, `src_shape` input will precede over `src_shape` attribute.

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

AvgPoolBackward operation supports the following data type combinations.

Diff_dst	Diff_src	Src_shape
f32	f32	s64
bf16	bf16	s64
f16	f16	s64

BatchNormForwardTraining

BatchNormForwardTraining operation performs batch normalization at training mode.

Mean and variance are computed at runtime, the following formulas are used:

- $\mu(c) = \frac{1}{NHW} \sum_{nhw} \text{src}(n, c, h, w),$
- $\sigma^2(c) = \frac{1}{NHW} \sum_{nhw} (\text{src}(n, c, h, w) - \mu(c))^2.$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>epsilon</i>	A number to be added to the variance to avoid division by zero	f32	A positive f32 value	Required
<i>momentum</i>	A number to be used to calculate running mean and running variance	f32	A positive f32 value	Optional
<i>data_format</i>	Controls how to interpret the shape of src and dst.	string	NCX, NYC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	mean	Required
2	variance	Required
3	gamma	Optional
4	beta (σ^2)	Optional

@note gamma and beta should be either both provided or neither provided.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required
1	running_mean	Required
2	running_variance	Required
3	batch_mean	Required
4	batch_variance	Required

Supported Data Types

BatchNormInference operation supports the following data type combinations.

Src / Dst	Gamma / Beta / Mean / Variance / Batch_mean / Batch_variance / Running_mean / Running_variance
f32	f32
bf16	f32, bf16
f16	f32

BatchNormInference

The formula is the same as *Batch Normalization primitive* :ref: `batch_normalization-label` like below.

$$\text{dst}(n, c, h, w) = \gamma(c) \cdot \frac{\text{src}(n, c, h, w) - \mu(c)}{\sqrt{\sigma^2(c) + \varepsilon}} + \beta(c),$$

where

- $\gamma(c), \beta(c)$ are required scale and shift for a channel,
- $\mu(c), \sigma^2(c)$ are mean and variance for a channel, and
- ε is a constant to improve numerical stability.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>epsilon</i>	A number to be added to the variance to avoid division by zero	f32	A positive float value	Required
<i>data_format</i>	Controls how to interpret the shape of src and dst.	string	NCX, NXC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	gamma	Required
2	beta	Required
3	mean	Required
4	variance (σ^2)	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

BatchNormInference operation supports the following data type combinations.

Src / Dst	Gamma / Beta / Mean / Variance
f32	f32
bf16	f32, bf16
f16	f32

BatchNormTrainingBackward

BatchNormTrainingBackward operation calculated the gradients of input tensors.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>epsilon</i>	A number to be added to the variance to avoid division by zero	f32	A positive f32 value	Required
<i>data_format</i>	Controls how to interpret the shape of src and dst.	string	NCX, NXC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required
2	mean	Required
3	variance	Required
4	gamma (σ^2)	Optional

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required
1	diff_gamma	Optional
2	diff_beta	Optional

@note `diff_gamma` and `diff_beta` should be either both provided or neither provided. If neither provided, the input `gamma` will be ignored.

Supported Data Types

BatchNormTrainingBackward operation supports the following data type combinations.

Src / Diff_dst / Dst	Mean / Variance / Gamma / Diff_gamma / Diff_beta
f32	f32
bf16	f32, bf16
f16	f32

BiasAdd

Add bias to channel dimension of input. This is a special Add with bias restricted to be 1-D. Broadcasting is supported.

$$\text{dst}(n, c, h, w) = \text{src}(n, c, h, w) + \text{bias}(c)$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX , NXC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	<i>src</i>	Required
1	<i>bias</i>	Required

@note *bias* is a 1D tensor to be added to *src* tensor. The size should be the same as size of channel dimension of *src* tensor.

Outputs

Index	Argument Name	Required or Optional
0	<i>dst</i>	Required

Supported Data Types

BiasAdd operation supports the following data type combinations.

Src	Bias	Dst
f32	f32	f32
bf16	bf16	bf16
f16	f16	f16

BiasAddBackward

BiasAddBackward operation computes the gradients on the bias tensor for BiasAdd operator. This op accumulates all the values from `diff_dst` into the channel dimension, the axis depends on the layout of `src` tensor.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<code>data_format</code>	Controls how to interpret the shape of <code>diff_dst</code> and <code>diff_bias</code> .	string	NCX , NXC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	<code>diff_dst</code>	Required

Outputs

Index	Argument Name	Required or Optional
0	<code>diff_bias</code>	Required

Supported Data Types

BiasAddBackward operation supports the following data type combinations.

<code>diff_dst</code>	<code>diff_bias</code>
f32	f32
bf16	bf16
f16	f16

Clamp

Clamp operation represents clipping activation function, it applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{clamp}(src_i) = \min(\max(src_i, \text{min_value}), \text{max_value})$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>min</i>	The lower bound of values in the output. Any value in the input that is smaller than the bound, is replaced with the <i>min</i> value.	f32	Arbitrary valid f32 value	Required
<i>max</i>	The upper bound of values in the output. Any value in the input that is greater than the bound, is replaced with the <i>max</i> value.	f32	Arbitrary valid f32 value	Required

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Clamp operation supports the following data type combinations.

Src	Dst
f32	f32
f16	f16
bf16	bf16

ClampBackward

ClampBackward operation computes gradient for Clamp.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>min</i>	The lower bound of values in the output. Any value in the input that is smaller than the bound, is replaced with the <i>min</i> value.	f32	Arbitrary valid f32 value	Required
<i>max</i>	The upper bound of values in the output. Any value in the input that is greater than the bound, is replaced with the <i>max</i> value.	f32	Arbitrary valid f32 value	Required
<i>use_dst</i>	If true, use <i>dst</i> of Clamp operation to calculate the gradient. Otherwise, use <i>src</i> .	bool	true (default), false	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src / dst	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

ClampBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

Concat

Concat operation concatenates N tensors over **axis** (here designated C) and is defined as (the variable names follow the standard *Conventions*):

$$\text{dst}(\overline{ou}, c, \overline{in}) = \text{src}_i(\overline{ou}, c', \overline{in}),$$

where $c = C_1 + .. + C_{i-1} + c'$.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axis</i>	Specifies dimension along which concatenation happens	s64	A s64 value in the range of [-r, r-1] where r = rank(src)	Required

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src_i	Required

@note At least one input tensor is required. Data types and ranks of all input tensors should match. The dimensions of all input tensors should be the same except for the dimension specified by axis attribute.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Concat operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

ConvTranspose

ConvTranspose operation performs the same computation as in ConvolutionBackwardData, except the source and destination are swapped.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the weights tensor is moved when computing convolution	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions	s64	A s64 list containing non-negative values	Required
<i>dilations</i>	Controls the amount of stretching the kernel before convolution	s64	A s64 list containing positive values (>1 means dilated convolution)	Required
<i>auto_pad</i>	Controls how the padding is calculated	string	none (default), same_upper, same_lower, valid	Optional
<i>output_padding</i>	Adds additional amount of padding per each spatial axis in <i>dst</i>	s64	A s64 list containing non-negative values, all zeros by default	Optional
<i>groups</i>	Controls how input channels and output channels are divided into	s64	A positive s64 value, 1 by default	Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX, NXC (default)	Optional
<i>weights_format</i>	Controls how to interpret the shape of <i>weights</i>	string	IOX, XOI (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	weights	Required
2	bias	Optional

@note The shape of weights is $(in_channels/groups, out_channels, spatial_shape)$ for IOX format or $(spatial_shape, out_channels, in_channels/groups)$ for XOI format. Both $in_channels$ and $out_channels$ must be divisible by $groups$ attribute.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

ConvTranspose operation supports the following data type combinations.

Src	Weights	Bias	Dst
f32	f32	f32	f32
bf16	bf16	bf16	bf16
f16	f16	f16	f16

ConvTransposeBackwardData

ConvTransposeBackwardData operation takes $diffdst$ and $weights$ and computes $diffsrc$.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the weights tensor is moved when computing convolution	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions	s64	A s64 list containing non-negative values	Required
<i>dilations</i>	Controls the amount of stretching the kernel before convolution	s64	A s64 list containing positive values (>1 means dilated convolution)	Required
<i>auto_pad</i>	Controls how the padding is calculated	string	none (default), same_upper, same_lower, valid	Optional
<i>output_padding</i>	Adds additional amount of padding per each spatial axis in <i>dst</i>	s64	A s64 list containing non-negative values, all zeros by default	Optional
<i>groups</i>	Controls how input channels and output channels are divided into	s64	A positive s64 value, 1 by default	Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX, NXC (default)	Optional
<i>weights_format</i>	Controls how to interpret the shape of <i>weights</i>	string	IOX, XOI (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	diff_dst	Required
1	weights	Required

@note The shape of weights is $(in_channels/groups, out_channels, spatial_shape)$ for IOX format or $(spatial_shape, out_channels, in_channels/groups)$ for XOI format. Both *in_channels* and *out_channels* must be divisible by *groups* attribute.

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

ConvTransposeBackwardData operation supports the following data type combinations.

Diff_dst	Weights	Diff_src
f32	f32	f32
bf16	bf16	bf16
f16	f16	f16

ConvTransposeBackwardWeights

ConvTransposeBackwardWeights operation takes diff_dst, src and optional *weights_shape* computes diff_weights.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the weights tensor is moved when computing convolution	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions	s64	A s64 list containing non-negative values	Required
<i>dilations</i>	Controls the amount of stretching the kernel before convolution	s64	A s64 list containing positive values (>1 means dilated convolution)	Required
<i>auto_pad</i>	Controls how the padding is calculated	string	none (default), same_upper, same_lower, valid	Optional
<i>output_padding</i>	Adds additional amount of padding per each spatial axis in <i>dst</i>	s64	A s64 list containing non-negative values, all zeros by default	Optional
<i>groups</i>	Controls how input channels and output channels are divided into	s64	A positive s64 value, 1 by default	Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX, NXC (default)	Optional
<i>weights_format</i>	Controls how to interpret the shape of <i>weights</i>	string	IOX, XOI (default)	Optional
<i>weights_shape</i>	Denotes the shape of the <i>weights</i> tensor	s64	A s64 list containing positive values	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required
2	weights_shape	Optional

@note The shape of weights is $(in_channels/groups, out_channels, spatial_shape)$ for IOX format or $(spatial_shape, out_channels, in_channels/groups)$ for XOI format. Both $in_channels$ and $out_channels$ must be divisible by $groups$ attribute.

@note Either $weights_shape$ input or $weights_shape$ attribute should be provided. If both provided, $weights_shape$ input will precede over the $weights_shape$ attribute.

Outputs

Index	Argument Name	Required or Optional
0	diff_weights	Required

Supported Data Types

ConvTransposeBackwardWeights operation supports the following data type combinations.

Src	Diff_dst	Diff_weights	Weights_shape
f32	f32	f32	s32
bf16	bf16	bf16	s32
f16	f16	f16	s32

Convolution

Convolution operation performs the convolution between src tensor and weight tensor, which is defined as by the following formulas. Variable names follow the standard *Conventions*.

Let src, weights and dst tensors have shape $N \times IC \times IH \times IW$, $OC \times IC \times KH \times KW$, and $N \times OC \times OH \times OW$ respectively.

Furthermore, let the remaining convolution parameters be:

Parameter	Depth	Height	Width	Comment
Paddings: Front, top, and left	PD_L	PH_L	PW_L	In the attributes we use <code>pads_begin</code> to indicate the corresponding vector of paddings
Padding: Back, bottom, and right	PD_R	PH_R	PW_R	In the attributes we use <code>pads_end</code> to indicate the corresponding vector of paddings
Stride	SD	SH	SW	In the attributes we use <code>strides</code> to indicate the corresponding vector of strides
Dilation	DD	DH	DW	In the attributes we use <code>dilations</code> to indicate the corresponding vector of dilations

To further simplify the formulas, we assume that the attribute `data_format` and `weights_format` are set to NCX and OIX respectively. NCX means the first axis represents batch dimension, the second axis represents channel dimension and the rest represents spatial dimensions. OIX means the first axis represents output channel dimension, the second axis represents input channel dimension and the rest represents weights spatial dimensions.

Regular Convolution

This is the same as the formula in *Convolution primitive* :ref: `convolution-label`.

$$\begin{aligned} \text{dst}(n, oc, oh, ow) &= \text{bias}(oc) \\ &+ \sum_{ic=0}^{IC-1} \sum_{kh=0}^{KH-1} \sum_{kw=0}^{KW-1} \text{src}(n, ic, oh', ow') \cdot \text{weights}(oc, ic, kh, kw). \end{aligned}$$

Here:

- $OH = \lfloor \frac{IH - KH + PH_L + PH_R}{SH} \rfloor + 1$,
- $OW = \lfloor \frac{IW - KW + PW_L + PW_R}{SW} \rfloor + 1$.

Convolution with Groups

The attribute `groups` is set to > 1 .

$$\begin{aligned} \text{dst}(n, g \cdot OC_G + oc_g, oh, ow) &= \text{bias}(g \cdot OC_G + oc_g) \\ &+ \sum_{ic_g=0}^{IC_G-1} \sum_{kh=0}^{KH-1} \sum_{kw=0}^{KW-1} \text{src}(n, g \cdot IC_G + ic_g, oh', ow') \cdot \text{weights}(g, oc_g, ic_g, kh, kw), \end{aligned}$$

where

- $IC_G = \frac{IC}{G}$,
- $OC_G = \frac{OC}{G}$, and
- $oc_g \in [0, OC_G)$.

Convolution with Dilation

The attribute *dilations* contains the element which is > 1 .

$$\text{dst}(n, oc, oh, ow) = \text{bias}(oc) + \sum_{ic=0}^{IC-1} \sum_{kh=0}^{KH-1} \sum_{kw=0}^{KW-1} \text{src}(n, ic, oh'', ow'') \cdot \text{weights}(oc, ic, kh, kw).$$

Here:

- $OH = \lfloor \frac{IH - DKH + PH_L + PH_R}{SH} \rfloor + 1$, where $DKH = 1 + (KH - 1) \cdot DH$, and
- $OW = \lfloor \frac{IW - DKW + PW_L + PW_R}{SW} \rfloor + 1$, where $DKW = 1 + (KW - 1) \cdot DW$.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the weights tensor is moved when computing convolution	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions	s64	A s64 list containing non-negative values	Required
<i>dilations</i>	Controls the amount of stretching the kernel before convolution	s64	A s64 list containing positive values (>1 means dilated convolution)	Required
<i>auto_pad</i>	Controls how the padding is calculated	string	none (default), same_upper, same_lower, valid	Optional
<i>groups</i>	Controls how input channels and output channels are divided into	s64	A positive s64 value, 1 by default	Optional
<i>data_format</i>	Controls how to interpret the shape of src and dst.	string	NCX, NXC (default)	Optional
<i>weights_format</i>	Controls how to interpret the shape of weights	string	OIX, XIO (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	weights	Required
2	bias	Optional

@note The shape of weights is $(out_channels, in_channels/groups, spatial_shape)$ for OIX format or $(spatial_shape, in_channels/groups, out_channels)$ for XIO format. Both $in_channels$ and $out_channels$ must be divisible by $groups$ attribute.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Convolution operation supports the following data type combinations.

Src	Weights	Bias	Dst
f32	f32	f32	f32
bf16	bf16	bf16	bf16
f16	f16	f16	f16

ConvolutionBackwardData

ConvolutionBackwardData operation accepts `diff_dst`, `weights` and optional `dst` shape as inputs, and compute the `diff_src`.

If `auto_pad` attribute is specified to one of `valid`, `same_upper` and `same_lower`, `pads_begin` and `pads_end` attributes will be ignored. The paddings will be calculated by following the below formula:

Let the parameters be:

Parameter	Depth	Height	Width	Comment
Paddings: Front, top, and left	PD_L	PH_L	PW_L	In the attributes we use <code>pads_begin</code> to indicate the corresponding vector of paddings
Padding: Back, bottom, and right	PD_R	PH_R	PW_R	In the attributes we use <code>pads_end</code> to indicate the corresponding vector of paddings
Stride	SD	SH	SW	In the attributes we use <code>strides</code> to indicate the corresponding vector of strides
Dilation	DD	DH	DW	In the attributes we use <code>dilations</code> to indicate the corresponding vector of dilations

Firstly, $total_padding$ is calculated according to src_shape and dst_shape . Let src_h be height dimension of src_shape and dst_h be height dimension of dst_shape .

$$total_padding_h = SH \times (src_h - 1) + ((KH - 1) \times DH + 1) - dst_h + output_padding_h$$

If `auto_pad` attribute is specified as `valid`:

$$PD_L = 0$$

$$PD_R = 0$$

If `auto_pad` attribute is specified as `same_lower`:

$$PD_L = \text{floor}(total_padding/2)$$

$$PD_R = total_padding - PD_L$$

If `auto_pad` attribute is specified as `same_upper`:

$$PD_L = total_padding - PD_R$$

$$PD_R = \text{floor}(total_padding/2)$$

where:

- dst_shape is either an attribute or an input tensor,
- $output_padding$ is an optional attribute.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the weights tensor is moved when computing convolution	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>dilations</i>	Controls the amount of stretching the kernel before convolution	s64	A s64 list containing positive values (>1 means dilated convolution)	Required
<i>auto_pad</i>	Controls how the padding is calculated	string	<i>none</i> (default), <i>same_upper</i> , <i>same_lower</i> , <i>valid</i>	Optional
<i>output_padding</i>	Adds additional amount of padding per each spatial axis in <i>dst</i>	s64	A s64 list containing non-negative values, all zeros by default	Optional
<i>groups</i>	Controls how input channels and output channels are divided into	s64	A positive s64 value, 1 by default	Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX, NXC (default)	Optional
<i>weights_format</i>	Controls how to interpret the shape of <i>weights</i>	string	OIX, XIO (default)	Optional
<i>dst_shape</i>	Denotes the shape of the <i>dst</i> tensor	s64	A s64 list containing positive values	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	diff_dst	Required
1	weights	Required
2	dst_shape	Optional

@note The shape of weights is $(out_channels, in_channels/groups, spatial_shape)$ for OIX format or $(spatial_shape, in_channels/groups, out_channels)$ for XIO format. Both $in_channels$ and $out_channels$ must be divisible by $groups$ attribute.

@note Either dst_shape input or dst_shape attribute should be provided. If both provided, dst_shape input will precede over dst_shape attribute.

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

ConvolutionBackwardData operation supports the following data type combinations.

Diff_dst	Weights	Diff_src	Dst_shape
f32	f32	f32	s32
bf16	bf16	bf16	s32
f16	f16	f16	s32

ConvolutionBackwardWeights

ConvolutionBackwardWeights operation accepts src , $diff_dst$ and optional weights shape as inputs, and compute the $diff_weights$.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the weights tensor is moved when computing convolution	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>dilations</i>	Controls the amount of stretching the kernel before convolution	s64	A s64 list containing positive values (>1 means dilated convolution)	Required
<i>auto_pad</i>	Controls how the padding is calculated	string	<i>none</i> (default), <i>same_upper</i> , <i>same_lower</i> , <i>valid</i>	Optional
<i>groups</i>	Controls how input channels and output channels are divided into	s64	A positive s64 value, 1 by default	Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX, NXC (default)	Optional
<i>weights_format</i>	Controls how to interpret the shape of <i>weights</i>	string	OIX, XIO (default)	Optional
<i>weights_shape</i>	Denotes the shape of the weights tensor	s64	A s64 list containing positive values	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required
2	weights_shape	Optional

@note The shape of weights is $(out_channels, in_channels/groups, spatial_shape)$ for OIX format or $(spatial_shape, in_channels/groups, out_channels)$ for XIO format. Both $in_channels$ and $out_channels$ must be divisible by $groups$ attribute.

@note Either $weights_shape$ input or $weights_shape$ attribute should be provided. If both provided, $weights_shape$ input will precede over $weights_shape$ attribute.

Outputs

Index	Argument Name	Required or Optional
0	diff_weights	Required

Supported Data Types

ConvolutionBackwardWeights operation supports the following data type combinations.

Src	Diff_dst	Diff_weights	Weights_shape
f32	f32	f32	s32
bf16	bf16	bf16	s32
f16	f16	f16	s32

Dequantize

Dequantize operation converts a quantized (u8 or s8) tensor to a f32 tensor. It supports both per-tensor and per-channel asymmetric linear de-quantization. Rounding mode is library-implementation defined.

For per-tensor de-quantization:

$$dst_{f32} = round((src_i - zps) \times scale)$$

For per-channel de-quantization, taking channel axis = 1 as an example:

$$dst_{\dots, i, \dots, \dots} = (src_{\dots, i, \dots, \dots} - zps_i) \times scale_i, i \in [0, ic - 1]$$

where ic is the number of channels.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>qtype</i>	Specifies which de-quantization type is used	string	<code>per_tensor</code> (default), <code>per_channel</code>	Optional
<i>axis</i>	Specifies dimension on which per-channel de-quantization is applied	s64	A s64 value in the range of $[-r, r-1]$ where $r = \text{rank}(\text{src})$, 1 by default	Optional
<i>scales</i>	Scalings applied on the src data	f32	A f32 list (only contain one element if <i>qtype</i> is <code>per_tensor</code>)	Required
<i>zps</i>	Offset values that maps to float zero	s64	A s64 list (only contain one element if <i>qtype</i> is <code>per_tensor</code>)	Required

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	<code>src</code>	Required

Outputs

Index	Argument Name	Required or Optional
0	<code>dst</code>	Required

Supported Data Types

Dequantize operation supports the following data type combinations.

Src	Dst
s8, u8	f32

@note This operation is to support *int8 quantization* model.

Divide

Divide operation performs element-wise division operation with two given tensors applying multi-directional broadcast rules.

$$\text{dst}(\bar{x}) = \text{src}_0(\bar{x}) / \text{src}_1(\bar{x}),$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>auto_broadcast</i>	Specifies rules used for auto-broadcasting of src tensors	string	none, numpy, (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src_0	Required
1	src_1	Required

@note Both src shapes should match and no auto-broadcasting is allowed if `auto_broadcast` attributes is `none`. `src_0` and `src_1` shapes can be different and auto-broadcasting is allowed if `auto_broadcast` attributes is `numpy`. Broadcasting is performed according to `auto_broadcast` value.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Divide operation supports the following data type combinations.

Diff_dst	Diff_bias
f32	f32
bf16	bf16
f16	f16

DynamicDequantize

DynamicDequantize operation converts a quantized (s8 or u8) tensor to a f32 tensor. It supports both per-tensor and per-channel asymmetric linear de-quantization. Rounding mode is library-implementation defined. Unlike the *Dequantize*, DynamicDequantize takes scales and zero-points as operator src tensors.

For per-tensor de-quantization

$$dst = (src - zps) * scales$$

For per-channel de-quantization, taking channel axis = 1 as an example:

$$dst_{\dots, i, \dots, \dots} = (src_{\dots, i, \dots, \dots} - zps_i) * scales_i, i \in [0, channelNum - 1]$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>qtype</i>	Specifies which de-quantization type is used	string	per_tensor (default), per_channel	Optional
<i>axis</i>	Specifies dimension on which per-channel de-quantization is applied	s64	A s64 value in the range of [-r, r-1] where r = rank(src), 1 by default	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	scales	Required
2	zps	Optional

@note scales is a f32 1D tensor to be applied to the de-quantization formula. For qtype = per-tensor, there should be only one element in the scales tensor. For qtype = per-channel, the element number should be equal to the element number of src tensor along the dimension axis.

@note zps is a 1D tensor with offset values that map to zero. For qtype = per-tensor, there should be only one element in the zps tensor. For qtype = per-channel, the element number should be equal to the element number of input tensor along the dimension axis. If not specified, the library can assume the operator is symmetric de-quantization and perform kernel optimization accordingly.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

DynamicDequantize operation supports the following data type combinations.

Src	Dst	Scales	Zps
s8	f32	f32	s8, u8, s32
u8	f32	f32	s8, u8, s32

DynamicQuantize

DynamicQuantize operation converts a f32 tensor to a quantized (s8 or u8) tensor. It supports both per-tensor and per-channel asymmetric linear quantization. The target quantized data type is specified via the data type of dst logical tensor. Rounding mode is library-implementation defined.

For per-tensor quantization:

$$dst_i = round(src_i / scale + zp)$$

For per-channel quantization, taking channel axis = 1 as an example:

$$dst_{\dots, i, \dots, \dots} = round(src_{\dots, i, \dots, \dots} / scale_i + zp_i), i \in [0, ic - 1]$$

where ic is the number of channels.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>qtype</i>	Specifies which de-quantization type is used	string	per_tensor (default), per_channel	Optional
<i>axis</i>	Specifies dimension on which per-channel de-quantization is applied	s64	A s64 value in the range of [-r, r-1] where r = rank(src), 1 by default	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	scales	Required
2	zps	Optional

@note `scales` is a f32 1D tensor to be applied to the quantization formula. For `qtype = per-tensor`, there should be only one element in the `scales` tensor. For `qtype = per-channel`, the element number should be equal to the element number of `src` tensor along the dimension axis.

@note `zps` is a 1D tensor with offset values that map to zero. For `qtype = per-tensor`, there should be only one element in the `zps` tensor. For `qtype = per-channel`, the element number should be equal to the element number of input tensor along the dimension axis. If not specified, the library can assume the operator is symmetric quantization and perform kernel optimization accordingly.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

DynamicQuantize operation supports the following data type combinations.

Src	Scales	Zps	Dst
f32	f32	s8, u8, s32	s8
f32	f32	s8, u8, s32	u8

Elu

Elu operation applies following formula on every element of `src` tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = \begin{cases} \alpha(e^{\text{src}} - 1) & \text{if } \text{src} < 0 \\ \text{src} & \text{if } \text{src} \geq 0 \end{cases}$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>alpha</i>	Scale for the negative factor.	f32	Arbitrary non-negative f32 value	Required

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Elu operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

EluBackward

EluBackward operation computes gradient for Elu operation.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>alpha</i>	Scale for the negative factor.	f32	Arbitrary non-negative f32 value	Required
<i>use_dst</i>	If true, use diffsrc of Elu operation to calculate the gradient. Otherwise, use src.	bool	true (default), false	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

EluBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

End

End operation is used to help construct graph, for example tracking the uses of a tensor.

Operation Attributes

End operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

End operation does not support output tensor.

Supported Data Types

End operation supports the following data type combinations.

Src	Destination
f32	f32
bf16	bf16
f16	f16

Exp

Exp operation is an exponential element-wise activation function, it applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$dst = e^{src}$$

Operation Attributes

Exp operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Exp operation supports the following data type combinations.

Src	Dst
f32	f32
f16	f16
bf16	bf16

GELU

GELU operation applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = 0.5 \text{src} \cdot (1.0 + \text{erf}(\text{src})/\sqrt{2})$$

Operation Attributes

GELU operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

GELU operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

GELUBackward

GELUBackward operation computes gradient for GELU.

Operation Attributes

GELUBackward operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

GELUBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

HardSwish

HardSwish operation applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = \text{src} * \frac{\min(\max(\text{src} + 3, 0), 6)}{6}$$

Operation Attributes

HardSwish operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

HardSwish operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

HardSwishBackward

HardSwishBackward operation computes gradient for HardSwish.

Operation Attributes

HardSwishBackward operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

HardSwishBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

Interpolate

Interpolate layer performs interpolation on src tensor at spatial dimensions.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>mode</i>	Specifies type of interpolation	string	nearest, linear, bilinear, trilinear	Required
<i>coordinate_transformation_mode</i>	Specifies how to transform the coordinate in the resized tensor to the coordinate in the original tensor	string	half_pixel (default), align_corners	Optional
<i>sizes</i>	Specifies dst shape for spatial axes.	s64	A s64 list containing positive values, none is default	Optional
<i>scales</i>	Specifies scales for spatial axes.	f32	A f32 list, none is default	Optional
<i>data_format</i>	Controls how to interpret the shape of src and dst	string	NCX, NXC (default)	Optional

@note Either sizes or scales should be provided. When sizes is used, scales will be ignored.

@note The attribute *coordinate_transformation_mode* is the name of transformation mode in string format. Here $scale[x]$ is $dst_shape[x]/src_shape[x]$ and $x_resized$ is a coordinate in axis x , for any axis x from the src axis. n
 For *half_pixel*: the coordinate in the original tensor axis x is calculated as $((x_resized + 0.5) / scale[x]) - 0.5$. n
 For *align_corners*: the coordinate in the original tensor axis x is calculated as 0 if $dst_shape[x] == 1$ else $x_resized * (src_shape[x] - 1) / (dst_shape[x] - 1)$.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	sizes	Optional

@note `sizes` is a 1D tensor describing output shape for spatial axes. It is a non-differentiable tensor.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

@note The shape of the `dst` matches `src` shape except spatial dimensions. For spatial dimensions, they should match sizes from `sizes` or calculated from `scales` attribute.

Supported Data Types

Interpolate operation supports the following data type combinations.

Src/Dst	Sizes
f32	s32
bf16	s32
f16	s3

InterpolateBackward

InterpolateBackward computes the gradients of Interpolate operation.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>mode</i>	Specifies type of interpolation	string	nearest, linear, bilinear, trilinear	Required
<i>coordinate_transformation_mode</i>	Specifies <i>mode</i> to transform the coordinate in the resized tensor to the coordinate in the original tensor	string	half_pixel (default), align_corners	Optional
<i>sizes</i>	Specifies dst shape for spatial axes.	s64	A s64 list containing positive values, none is default	Optional
<i>scales</i>	Specifies scales for spatial axes.	f32	A f32 list, none is default	Optional
<i>data_format</i>	Controls how to interpret the shape of src and dst	string	NCX, NXC (default)	Optional

@note Either sizes or scales should be provided. When sizes is used, scales will be ignored.

@note The attribute *coordinate_transformation_mode* is the name of transformation mode in string format.
 Here $scale[x]$ is $dst_shape[x]/src_shape[x]$ and $x_resized$ is a coordinate in axis x , for any axis x from the src axis.
 For *half_pixel*: the coordinate in the original tensor axis x is calculated as $((x_resized + 0.5) / scale[x]) - 0.5$.
 For *align_corners*: the coordinate in the original tensor axis x is calculated as 0 if $dst_shape[x] == 1$ else $x_resized * (src_shape[x] - 1) / (dst_shape[x] - 1)$.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required
2	sizes	Optional

@note src is original input tensor of Interpolate op.
 diff_dst is the gradient tensor with respect to the dst.
 sizes is a 1D tensor describing output shape for spatial axes.

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

@note diff_src is the gradient tensor with respect to the src of Interpolate.

Supported Data Types

InterpolateBackward operation supports the following data type combinations.

Src/Diff_dst/Diff_src	Sizes
f32	s32
bf16	s32
f16	s32

LayerNorm

LayerNorm performs a layer normalization operation on src tensor.

The layerNorm operation performs normalization from `begin_norm_axis` to last dimension of the data tensor. It is defined by the following formulas which is the same as *Layer normalization*.

$$\text{dst}(t, n, c) = \gamma(c) \cdot \frac{\text{src}(t, n, c) - \mu(t, n)}{\sqrt{\sigma^2(t, n) + \epsilon}} + \beta(c),$$

where

- $\gamma(c), \beta(c)$ are optional scale and shift for a channel
- $\mu(t, n), \sigma^2(t, n)$ are mean and variance (see
- ϵ is a constant to improve numerical stability.

Mean and variance are computed at runtime or provided by a user. When mean and variance are computed at runtime, the following formulas are used:

- $\mu(t, n) = \frac{1}{C} \sum_c \text{src}(t, n, c),$
- $\sigma^2(t, n) = \frac{1}{C} \sum_c (\text{src}(t, n, c) - \mu(t, n))^2.$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>keep_stats</i>	Indicate whether to output mean and variance which can be later passed to backward op	bool	false, true (default)	Optional
<i>begin_norm_axis</i>	<i>begin_norm_axis</i> is used to indicate which axis to start layer normalization. The normalization is from <i>begin_norm_axis</i> to last dimension. Negative values means indexing from right to left. This op normalizes over the last dimension by default, e.g. C in TNC for 3D and LDNC for 4D.	s64	[-r,r-1],where r=rank(src). -1 is default	Optional
<i>use_affine</i>	When set to True, this module has learnable per-element affine parameters.	bool	false, true (default)	Optional
<i>epsilon</i>	The constant to improve numerical stability	f32	Arbitrary positive f32 value, 1e-5 (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	gamma	Optional
2	beta	Optional

@note *gamma* is scaling for normalized value. *beta* is the bias added to the scaled normalized value. They are both 1D tensor with the same span as *src*'s channel axis and required if attribute *use_affine* is set to True.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required
1	mean	Optional
2	variance	Optional

@note Both mean and variance are required if attribute keep_stats is set to True.

Supported Data Types

LayerNorm operation supports the following data type combinations.

Src / Dst	Gamma / Beta / Mean / Variance
f32	f32
bf16	f32, bf16
f16	f32

LayerNormBackward

LayerNormBackward performs the backward of LayerNorm operation.

The backward propagation computes $\text{diff_src}(t, n, c)$, $\text{diff_}\gamma(c)^*$, and $\text{diff_}\beta(c)^*$ based on $\text{diff_dst}(t, n, c)$, $\text{src}(t, n, c)$, $\mu(t, n)$, $\sigma^2(t, n)$, $\gamma(c)^*$, and $\beta(c)^*$.

The tensors marked with an asterisk are used only when the operation is configured to use $\gamma(c)$, and $\beta(c)$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>begin_norm_axis</i>	<i>begin_norm_axis</i> is used to indicate which axis to start layer normalization. The normalization is from <i>begin_norm_axis</i> to last dimension. Negative values means indexing from right to left. This op normalizes over the last dimension by default, e.g. C in TNC for 3D and LDNC for 4D.	s64	[-r,r-1],where r=rank(src). -1 is default	Optional
<i>use_affine</i>	When set to True, this module has learnable per-element affine parameters.	bool	false, true (default)	Optional
<i>epsilon</i>	The constant to improve numerical stability	f32	Arbitrary positive f32 value, 1e-5 (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required
2	mean	Required
3	variance	Required
4	gamma	Optional
5	beta	Optional

@note gamma is scaling for normalized value. beta is the bias added to the scaled normalized value. They are both 1D tensor with the same span as src's channel axis and required if attribute *use_affine* is set to True.

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required
1	diff_gamma	Optional
2	diff_beta	Optional

Supported Data Types

LayerNormBackward operation supports the following data type combinations.

Src / Diff_dst / Diff_src	Gamma / Beta / Mean / Variance / Diff_gamma / Diff_beta
f32	f32
bf16	f32, bf16
f16	f32

LeakyReLU

LeakyReLU operation is a type of activation function based on ReLU. It has a small slope for negative values with which LeakyReLU can produce small, non-zero, and constant gradients with respect to the negative values. The slope is also called the coefficient of leakage.

Unlike *PReLU*, the coefficient α is constant and defined before training.

LeakyReLU operation applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = \begin{cases} \text{src} & \text{if } \text{src} \geq 0 \\ \alpha \text{ src} & \text{if } \text{src} < 0 \end{cases}$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>alpha</i>	Alpha is the coefficient of leakage.	f32	Arbitrary f32 value but usually a small positive value.	Required

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

LeakyReLU operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

Log

Log operation performs element-wise natural logarithm operation with given tensor, it applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = \log(\text{src})$$

Operation Attributes

Log operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Log operation supports the following data type combinations.

Src	Dst
f32	f32
f16	f16
bf16	bf16

LogSoftmax

LogSoftmax operation applies the $\log(\text{softmax}(\text{src}))$ function to an n-dimensional input Tensor. The formulation can be simplified as:

$$\text{dst}_i = \log \left(\frac{e^{\text{src}_i}}{\sum_j e^{\text{src}_j}} \right)$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axis</i>	Represents the axis of which the LogSoftmax is calculated.	s64	Arbitrary s64 value (-1 in default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

LogSoftmax operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

LogSoftmaxBackward

LogSoftmaxBackward operation computes gradient for LogSoftmax.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axis</i>	Represents the axis of which the LogSoftmax is calculated.	s64	Arbitrary s64 value (-1 in default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	diff_dst	Required
1	src	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

LogSoftmaxBackward operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

MatMul

MatMul operation computes the product of two tensors with optional bias addition. The variable names follow the standard *Conventions*, typically taking 2D input tensors as an example, the formula is below:

$$\text{dst}(m, n) = \sum_{k=0}^{K-1} (\text{src}(m, k) \cdot \text{weights}(k, n)) + \text{bias}(m, n)$$

In the shape of a tensor, two right-most axes are interpreted as row and column dimensions of a matrix while all left-most axes (if present) are interpreted as batch dimensions. The operation supports broadcasting semantics for those batch dimensions. For example src can be broadcasted to weights if the corresponding dimension in src is 1 (and vice versa). Additionally, if ranks of src and weights are different, the tensor with a smaller rank will be *unsqueezed* from the left side of dimensions (inserting 1) to make sure two ranks matched.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>transpose_a</i>	Controls whether to transpose the last two dimensions of src	bool	True, False (default)	Optional
<i>transpose_b</i>	Controls whether to transpose the last two dimensions of weights	bool	True, False (default)	Optional

The above transpose attributes will not be in effect when rank of an input tensor is less than 2. For example, in library implementation 1D tensor is unsqueezed firstly before compilation. The rule is applied independently.

- For src tensor, the rule is defined like: [d] -> [1, d].
- For weights tensor, the rule is defined like: [d] -> [d, 1].

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	weights	Required
2	bias	Optional

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

MatMul operation supports the following data type combinations.

Src	Weights	Bias	Dst
f32	f32	f32	f32
bf16	bf16	bf16	bf16
f16	f16	f16	f16

MaxPool

MaxPool operation performs the computation following the below formulas. Variable names follow the standard *Conventions*.

$$\text{dst}(n, c, oh, ow) = \max_{kh, kw} (\text{src}(n, c, oh \cdot SH + kh \cdot (DH + 1) - PH_L, ow \cdot SW + kw \cdot (DW + 1) - PW_L))$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the window is moved	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>kernel</i>	Size of pooling window	s64	A s64 list containing positive values	Required
<i>dilations</i>	Denotes the distance in width and height between elements.	s64	A s64 list containing positive values, a list of 1 s (default) means no dilation	Optional
<i>rounding_type</i>	Controls how to do rounding	string	<i>floor</i> (default), <i>ceil</i>	Optional
<i>auto_pad</i>	Controls how the paddings are calculated	string	<i>none</i> (default), <i>same_upper</i> , <i>same_lower</i> , <i>valid</i>	Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX, NXC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

MaxPool operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

MaxPoolBackward

AvgPoolBackward operation accepts src tensor and diff_dst tensor, and calculates diff_src tensor.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>strides</i>	Controls the strides the window is moved	s64	A s64 list containing positive values	Required
<i>pads_begin</i>	Controls number of zeros to be add to the front/top/left of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>pads_end</i>	Controls number of zeros to be add to the back/bottom/right of spatial dimensions, the attribute will be ignored when <i>auto_pad</i> attribute is specified to <i>same_upper</i> , <i>same_lower</i> or <i>valid</i>	s64	A s64 list containing non-negative values	Required
<i>kernel</i>	Size of pooling window	s64	A s64 list containing positive values	Required
<i>dilations</i>	Denotes the distance in width and height between elements.	s64	A s64 list containing positive values, a list of 1 s (default) means no dilation	Optional
<i>auto_pad</i>	Controls how the paddings are calculated	string	<i>none</i> (default), <i>same_upper</i> , <i>same_lower</i> , <i>valid</i>	Optional
<i>data_format</i>	Controls how to interpret the shape of <i>src</i> and <i>dst</i> .	string	NCX, NXC (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

MaxPoolBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
bf16	bf16	bf16
f16	f16	f16

Maximum

Maximum operation performs element-wise maximum operation with two given tensors applying multi-directional broadcast rules.

$$\text{dst}(\bar{x}) = \max(\text{src}_0(\bar{x}), \text{src}_1(\bar{x}))$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>auto_broadcast</i>	Specifies rules used for auto-broadcasting of src tensors	string	none, numpy, (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src_0	Required
1	src_1	Required

@note Both src shapes should match and no auto-broadcasting is allowed if `auto_broadcast` attributes is `none`. `src_0` and `src_1` shapes can be different and auto-broadcasting is allowed if `auto_broadcast` attributes is `numpy`. Broadcasting is performed according to `auto_broadcast` value.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Maximum operation supports the following data type combinations.

Source0/1	Destination
f32	f32
bf16	bf16
f16	f16

Minimum

Minimum operation performs element-wise minimum operation with two given tensors applying multi-directional broadcast rules.

$$\text{dst}(\bar{x}) = \min(\text{src}_0(\bar{x}), \text{src}_1(\bar{x}))$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<code>auto_broadcast</code>	Specifies rules used for auto-broadcasting of src tensors	string	none, numpy, (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src_0	Required
1	src_1	Required

@note Both src shapes should match and no auto-broadcasting is allowed if `auto_broadcast` attributes is `none`. `src_0` and `src_1` shapes can be different and auto-broadcasting is allowed if `auto_broadcast` attributes is `numpy`. Broadcasting is performed according to `auto_broadcast` value.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Minimum operation supports the following data type combinations.

Source0/1	Destination
f32	f32
bf16	bf16
f16	f16

Mish

Mish performs element-wise activation function on a given input tensor, based on the following mathematical formula:

$$\text{dst} = \text{src} * \tanh(\text{SoftPlus}(\text{src})) = \text{src} * \tanh(\ln(1 + e^{\text{src}}))$$

Operation Attributes

Mish operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Mish operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

MishBackward

MishBackward operation computes gradient for Mish.

$$\text{dst} = \text{diff_dst} * \frac{e^{\text{src}} * \omega}{\delta^2}$$

where

$$\begin{aligned} \omega &= e^{3 \text{src}} + 4 * e^{2 \text{src}} + e^{\text{src}} * (4 * \text{src} + 6) + 4 * (\text{src} + 1) \\ \delta &= e^{2 \text{src}} + 2 * e^{\text{src}} + 2 \end{aligned}$$

Operation Attributes

MishBackward operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

MishBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

Multiply

Multiply operation performs element-wise multiply operation with two given tensors applying multi-directional broadcast rules.

$$\text{dst}(\bar{x}) = \text{src}_0(\bar{x}) \times \text{src}_1(\bar{x}),$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>auto_broadcast</i>	Specifies rules used for auto-broadcasting of src tensors	string	none, numpy, (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src_0	Required
1	src_1	Required

@note Both src shapes should match and no auto-broadcasting is allowed if auto_broadcast attributes is none. src_0 and src_1 shapes can be different and auto-broadcasting is allowed if auto_broadcast attributes is numpy. Broadcasting is performed according to auto_broadcast value.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Multiply operation supports the following data type combinations.

Source0/1	Destination
f32	f32
bf16	bf16
f16	f16

PReLU

PReLU operation performs element-wise parametric ReLU operation on a given input tensor, based on the following mathematical formula:

$$\text{dst} = \begin{cases} \text{src} & \text{if } \text{src} \geq 0 \\ \alpha \text{src} & \text{if } \text{src} < 0 \end{cases}$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>data_format</i>	Denotes the data format of the input and output data.	string	NCX, NXC (default)	Optional
<i>per_channel_broadcast</i>	Denotes whether to apply per_channel broadcast when slope is 1D tensor.	bool	false, true (default)	Optional

Broadcasting Rules

Only slope tensor supports broadcasting semantics. Slope tensor is uni-directionally broadcasted to src if one of the following rules is met:

- 1: slope is 1D tensor and `per_channel_broadcast` is set to `true`, the length of slope tensor is equal to the length of src of channel dimension.
- 2: slope is 1D tensor and `per_channel_broadcast` is set to `false`, the length of slope tensor is equal to the length of src of the rightmost dimension.
- 3: slope is nD tensor, starting from the rightmost dimension, $input.shape_i == slope.shape_i$ or $slope.shape_i == 1$ or slope dimension i is empty.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	slope	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

PReLU operation supports the following data type combinations.

Src	Dst	Slope
f32	f32	f32
bf16	bf16	bf16
f16	f16	f16

PReLUBackward

PReLUBackward operation computes gradient for PReLU.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>data_format</i>	Denotes the data format of the input and output data.	string	NCX, NXC (default)	Optional

Broadcasting Rules

Only slope tensor supports broadcasting semantics. Slope tensor is uni-directionally broadcasted to src if one of the following rules is met:

- 1: PyTorch case: slope is 1D tensor and broadcast per channel, length of slope is equal to the length of src in channel dimension.
- 2: PyTorch case: slope is 1D tensor and broadcast per tensor, length of slope is equal to 1.
- 3: Tensorflow case: slope is nD tensor and its dimensions must be equal to the src dimensions starting from the second element: \$ slope_shape = input_forward_shape[1:] \$

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	slope	Required
2	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required
1	diff_slope	Required

Supported Data Types

PReLUBackward operation supports the following data type combinations.

Src	Slope	Diff_dst	Diff_src	Diff_slope
f32	f32	f32	f32	f32
bf16	bf16	bf16	bf16	bf16
f16	f16	f16	f16	f16

Quantize

Quantize operation converts a f32 tensor to a quantized (u8/s8) tensor. It supports both per-tensor and per-channel asymmetric linear quantization. Output data type is specified in output tensor data type. Rounding mode is library-implementation defined.

For per-tensor quantization:

$$dst_i = round(src_i / scale + zp)$$

For per-channel quantization, taking channel axis = 1 as an example:

$$dst_{... , i, ... , ...} = round(src_{... , i, ... , ...} / scale_i + zp_i), i \in [0, ic - 1]$$

where ic is the number of channels.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>qtype</i>	Specifies which de-quantization type is used	string	<code>per_tensor</code> (default), <code>per_channel</code>	Optional
<i>axis</i>	Specifies dimension on which per-channel de-quantization is applied	s64	A s64 value in the range of [-r, r-1] where r = rank(src), 1 by default	Optional
<i>scales</i>	Scalings applied on the src data	f32	A f32 list (only contain one element if qtype is <code>per_tensor</code>)	Required
<i>zps</i>	Offset values that maps to float zero	s64	A s64 list (only contain one element if qtype is <code>per_tensor</code>)	Required

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	<code>src</code>	Required

Outputs

Index	Argument Name	Required or Optional
0	<code>dst</code>	Required

Supported Data Types

Quantize operation supports the following data type combinations.

Src	Dst
f32	s8, u8

@note This operation is to support *int8 quantization* model.

ReLU

ReLU applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = \begin{cases} \text{src} & \text{if } \text{src} > 0 \\ 0 & \text{if } \text{src} \leq 0 \end{cases}$$

Operation Attributes

ReLU operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

ReLU operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

ReLUBackward

ReLUBackward operation computes gradient for ReLU.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>use_dst</i>	If true, use dst of ReLU operation to calculate the gradient. Otherwise, use src.	bool	true (default), false	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src / dst	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

ReLUBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

Reciprocal

Reciprocal operation is element-wise Power operation where exponent(power) equals to -1. Reciprocal of 0 is infinity.

$$\text{dst} = \begin{cases} \text{src}^{-1} & \text{if } \text{src} \neq 0 \\ \infty & \text{if } \text{src} = 0 \end{cases}$$

Operation Attributes

Reciprocal operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Reciprocal operation supports the following data type combinations.

Source	Destination
f32	f32
bf16	bf16
f16	f16

ReduceL1

ReduceL1 operation performs the reduction with finding the L1 norm (sum of absolute values) on a given src data along dimensions specified by axes.

Take channel axis = 0 and keep_dims = True as an example:

$$\text{dst}_{0,\dots,\dots} = \sum_i |\text{src}_{i,\dots,\dots}|, i \in [0, \text{channelNum} - 1]$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axes</i>	Specify indices of src tensor, along which the reduction is performed. If axes is a list, reduce over all of them. If axes is empty, corresponds to the identity operation. If axes contains all dimensions of src tensor, a single reduction value is calculated for the entire src tensor. Exactly one of attribute <i>axes</i> and the second input tensor <i>axes</i> should be available.	s64	A s64 list values which is in the range of $[-r, r-1]$ where $r = \text{rank}(\text{src})$. Empty list(default)	Optional
<i>keep_dims</i>	If set to true it holds axes that are used for reduction. For each such axes, dst dimension is equal to 1.	bool	true, false (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	axes	Optional

@note *axes* is an 1-D tensor specifying the axis along which the reduction is performed. 1D tensor of unique elements. The range of elements is $[-r, r-1]$, where r is the rank of src tensor. Exactly one of attribute *axes* and the second input tensor *axes* should be available.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

@note The result of ReduceL1 function applied to src tensor. $\text{shape}[i] = \text{shapeOf}(\text{data})[i]$ for all i that is not in the list of axes from the second input. For dimensions from axes, $\text{shape}[i] == 1$ if $\text{keep_dims} == \text{True}$, or i -th dimension is removed from the dst otherwise.

Supported Data Types

ReduceL1 operation supports the following data type combinations.

Source/Destination	Axes
f32	s32
bf16	s32
f16	s32

ReduceL2

ReduceL2 operation performs the reduction with finding the L2 norm (square root of sum of squares) on a given src data along dimensions specified by axes.

Take channel axis = 0 and $\text{keep_dims} = \text{True}$ as an example:

$$\text{dst}_{0,\dots,\dots} = \sqrt{\sum_i \text{src}_{i,\dots,\dots}^2}, i \in [0, \text{channelNum} - 1]$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axes</i>	Specify indices of src tensor, along which the reduction is performed. If axes is a list, reduce over all of them. If axes is empty, corresponds to the identity operation. If axes contains all dimensions of src tensor, a single reduction value is calculated for the entire src tensor. Exactly one of attribute <i>axes</i> and the second input tensor <i>axes</i> should be available.	s64	A s64 list values which is in the range of $[-r, r-1]$ where $r = \text{rank}(\text{src})$. Empty list(default)	Optional
<i>keep_dims</i>	If set to true it holds axes that are used for reduction. For each such axes, dst dimension is equal to 1.	bool	true, false (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	axes	Optional

@note *axes* is an 1-D tensor specifying the axis along which the reduction is performed. 1D tensor of unique elements. The range of elements is $[-r, r-1]$, where r is the rank of src tensor. Exactly one of attribute *axes* and the second input tensor *axes* should be available.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

@note The result of ReduceL2 function applied to src tensor. $\text{shape}[i] = \text{shapeOf}(\text{data})[i]$ for all i that is not in the list of axes from the second input. For dimensions from axes, $\text{shape}[i] == 1$ if $\text{keep_dims} == \text{True}$, or i -th dimension is removed from the dst otherwise.

Supported Data Types

ReduceL2 operation supports the following data type combinations.

Source/Destination	Axes
f32	s32
bf16	s32
f16	s32

ReduceMax

ReduceMax operation performs the reduction with finding the maximum value on a given src data along dimensions specified by axes.

Take channel axis = 0 and $\text{keep_dims} = \text{True}$ as an example:

$$\text{dst}_{0,\dots,\dots} = \max \text{src}_{i,\dots,\dots}, i \in [0, \text{channelNum} - 1]$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axes</i>	Specify indices of src tensor, along which the reduction is performed. If axes is a list, reduce over all of them. If axes is empty, corresponds to the identity operation. If axes contains all dimensions of src tensor, a single reduction value is calculated for the entire src tensor. Exactly one of attribute <i>axes</i> and the second input tensor <i>axes</i> should be available.	s64	A s64 list values which is in the range of [-r,r-1] where r = rank(src). Empty list(default)	Optional
<i>keep_dims</i>	If set to true it holds axes that are used for reduction. For each such axes, dst dimension is equal to 1.	bool	true, false (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	axes	Optional

@note *axes* is an 1-D tensor specifying the axis along which the reduction is performed. 1D tensor of unique elements. The range of elements is [-r, r-1], where r is the rank of src tensor. Exactly one of attribute *axes* and the second input tensor *axes* should be available.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

@note The result of ReduceMax function applied to src tensor. $\text{shape}[i] = \text{shapeOf}(\text{data})[i]$ for all i that is not in the list of axes from the second input. For dimensions from axes, $\text{shape}[i] == 1$ if $\text{keep_dims} == \text{True}$, or i -th dimension is removed from the dst otherwise.

Supported Data Types

ReduceMax operation supports the following data type combinations.

Source/Destination	Axes
f32	s32
bf16	s32
f16	s32

ReduceMean

ReduceMean operation performs the reduction with finding the arithmetic mean on a given src data along dimensions specified by axes.

Take channel axis = 0 and $\text{keep_dims} = \text{True}$ as an example:

$$\text{dst}_{0,\dots,\dots} = \frac{1}{\text{channelNum}} \cdot \sum_i \text{src}_{i,\dots,\dots}, i \in [0, \text{channelNum} - 1]$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axes</i>	Specify indices of src tensor, along which the reduction is performed. If axes is a list, reduce over all of them. If axes is empty, corresponds to the identity operation. If axes contains all dimensions of src tensor, a single reduction value is calculated for the entire src tensor. Exactly one of attribute <i>axes</i> and the second input tensor <i>axes</i> should be available.	s64	A s64 list values which is in the range of $[-r, r-1]$ where $r = \text{rank}(\text{src})$. Empty list(default)	Optional
<i>keep_dims</i>	If set to true it holds axes that are used for reduction. For each such axes, dst dimension is equal to 1.	bool	true, false (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	axes	Optional

@note *axes* is an 1-D tensor specifying the axis along which the reduction is performed. 1D tensor of unique elements. The range of elements is $[-r, r-1]$, where r is the rank of src tensor. Exactly one of attribute *axes* and the second input tensor *axes* should be available.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

@note The result of ReduceMean function applied to src tensor. $\text{shape}[i] = \text{shapeOf}(\text{data})[i]$ for all i that is not in the list of axes from the second input. For dimensions from axes, $\text{shape}[i] == 1$ if $\text{keep_dims} == \text{True}$, or i -th dimension is removed from the dst otherwise.

Supported Data Types

ReduceMean operation supports the following data type combinations.

Source/Destination	Axes
f32	s32
bf16	s32
f16	s32

ReduceMin

ReduceMin operation performs the reduction with finding the minimum value on a given src data along dimensions specified by axes.

Take channel axis = 0 and keep_dims = True as an example:

$$\text{dst}_{0,\dots,\dots} = \min \text{src}_{i,\dots,\dots}, i \in [0, \text{channelNum} - 1]$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axes</i>	Specify indices of src tensor, along which the reduction is performed. If axes is a list, reduce over all of them. If axes is empty, corresponds to the identity operation. If axes contains all dimensions of src tensor, a single reduction value is calculated for the entire src tensor. Exactly one of attribute <i>axes</i> and the second input tensor <i>axes</i> should be available.	s64	A s64 list values which is in the range of $[-r, r-1]$ where $r = \text{rank}(\text{src})$. Empty list(default)	Optional
<i>keep_dims</i>	If set to true it holds axes that are used for reduction. For each such axes, dst dimension is equal to 1.	bool	true, false (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	axes	Optional

@note *axes* is an 1-D tensor specifying the axis along which the reduction is performed. 1D tensor of unique elements. The range of elements is $[-r, r-1]$, where r is the rank of src tensor. Exactly one of attribute *axes* and the second input tensor *axes* should be available.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

@note The result of ReduceMin function applied to src tensor. $\text{shape}[i] = \text{shapeOf}(\text{data})[i]$ for all i that is not in the list of axes from the second input. For dimensions from axes, $\text{shape}[i] == 1$ if $\text{keep_dims} == \text{True}$, or i -th dimension is removed from the dst otherwise.

Supported Data Types

ReduceMin operation supports the following data type combinations.

Source/Destination	Axes
f32	s32
bf16	s32
f16	s32

ReduceProd

ReduceProd operation performs the reduction with multiplication on a given src data along dimensions specified by axes.

Take channel axis = 0 and $\text{keep_dims} = \text{True}$ as an example:

$$\text{dst}_{0,\dots} = \prod_i \text{src}_{i,\dots}, i \in [0, \text{channelNum} - 1]$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axes</i>	Specify indices of src tensor, along which the reduction is performed. If axes is a list, reduce over all of them. If axes is empty, corresponds to the identity operation. If axes contains all dimensions of src tensor, a single reduction value is calculated for the entire src tensor. Exactly one of attribute <i>axes</i> and the second input tensor <i>axes</i> should be available.	s64	A s64 list values which is in the range of $[-r, r-1]$ where $r = \text{rank}(\text{src})$. Empty list(default)	Optional
<i>keep_dims</i>	If set to true it holds axes that are used for reduction. For each such axes, dst dimension is equal to 1.	bool	true, false (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	axes	Optional

@note *axes* is an 1-D tensor specifying the axis along which the reduction is performed. 1D tensor of unique elements. The range of elements is $[-r, r-1]$, where r is the rank of src tensor. Exactly one of attribute *axes* and the second input tensor *axes* should be available.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

@note The result of ReduceProd function applied to src tensor. $\text{shape}[i] = \text{shapeOf}(\text{data})[i]$ for all i that is not in the list of axes from the second input. For dimensions from axes, $\text{shape}[i] == 1$ if $\text{keep_dims} == \text{True}$, or i -th dimension is removed from the dst otherwise.

Supported Data Types

ReduceProd operation supports the following data type combinations.

Source/Destination	Axes
f32	s32
bf16	s32
f16	s32

ReduceSum

ReduceSum operation performs the reduction with addition on a given src data along dimensions specified by axes.

Take channel axis = 0 and keep_dims = True as an example:

$$\text{dst}_{0,\dots,\dots} = \sum_i \text{src}_{i,\dots,\dots}, i \in [0, \text{channelNum} - 1]$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axes</i>	Specify indices of src tensor, along which the reduction is performed. If axes is a list, reduce over all of them. If axes is empty, corresponds to the identity operation. If axes contains all dimensions of src tensor, a single reduction value is calculated for the entire src tensor. Exactly one of attribute <i>axes</i> and the second input tensor <i>axes</i> should be available.	s64	A s64 list values which is in the range of [-r,r-1] where r = rank(src). Empty list(default)	Optional
<i>keep_dims</i>	If set to true it holds axes that are used for reduction. For each such axes, dst dimension is equal to 1.	bool	true, false (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	axes	Optional

@note *axes* is an 1-D tensor specifying the axis along which the reduction is performed. 1D tensor of unique elements. The range of elements is [-r, r-1], where r is the rank of src tensor. Exactly one of attribute *axes* and the second input tensor *axes* should be available.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

@note The result of ReduceSum function applied to src tensor. $\text{shape}[i] = \text{shapeOf}(\text{data})[i]$ for all i that is not in the list of axes from the second input. For dimensions from axes, $\text{shape}[i] == 1$ if $\text{keep_dims} == \text{True}$, or i -th dimension is removed from the dst otherwise.

Supported Data Types

ReduceSum operation supports the following data type combinations.

Source/Destination	Axes
f32	s32
bf16	s32
f16	s32

Reorder

Reorder operation converts src tensor to dst tensor with different layout. It supports the conversion between:

- two different opaque layouts
- two different strided layouts
- one strided layout and another opaque layout

Reorder operation does not support layout conversion cross different backends or different engines. Unlike *reorder primitive* :ref: `reorder-label`, Reorder operation cannot be used to cast the data type from src to dst. Please check the usage of *TypeCast* :ref: `op_typecast-label` and *Dequantize* :ref: `op_dequantize-label` operation.

Operation Attributes

Reorder operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Reorder operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

Round

Round operation rounds the values of a tensor to the nearest integer, element-wise.

Operation Attributes

Round operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Round operation supports the following data type combinations.

Src	Dst
f32	f32
f16	f16
bf16	bf16

Sigmoid

Sigmoid operation applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = \frac{1}{1 + e^{-\text{src}}}$$

Operation Attributes

Sigmoid operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Sigmoid operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

SigmoidBackward

SigmoidBackward operation computes gradient for Sigmoid.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>use_dst</i>	If true, use dst of Sigmoid operation to calculate the gradient. Otherwise, use src.	bool	true (default), false	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src / dst	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

SigmoidBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

SoftPlus

SoftPlus operation applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = 1 / \beta \ln(e^{\beta * \text{src}} + 1.0)$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>beta</i>	Value for the Soft-Plus formulation.	s64	Arbitrary s64 value (1 in default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

SoftPlus operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

SoftPlusBackward

SoftPlusBackward operation computes gradient for SoftPlus.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>beta</i>	Value for the Soft-Plus formulation.	s64	Arbitrary s64 value (1 in default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

SoftPlusBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
bf16	bf16	bf16
f16	f16	f16

Softmax

Softmax operation applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$dst_i = \frac{e^{(src_i)}}{\sum_{j=1}^C e^{src_j}}$$

where \$ C \$ is a size of tensor along axis dimension.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axis</i>	Represents the axis of which the Softmax is calculated.	s64	Arbitrary s64 value (1 in default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Softmax operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

SoftmaxBackward

SoftmaxBackward operation computes gradient for Softmax.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>axis</i>	Represents the axis of which the Softmax is calculated.	s64	Arbitrary s64 value (1 in default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	<code>diff_dst</code>	Required
1	<code>src</code>	Required

Outputs

Index	Argument Name	Required or Optional
0	<code>diff_src</code>	Required

Supported Data Types

SoftmaxBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
bf16	bf16	bf16
f16	f16	f16

Sqrt

Sqrt operation performs element-wise square root operation with given tensor.

Operation Attributes

Sqrt operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Sqrt operation supports the following data type combinations.

Src	Dst
f32	f32
f16	f16
bf16	bf16

SqrtBackward

SqrtBackward operation computes gradient for Sqrt.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>use_dst</i>	If true, use dst of Sqrt operation to calculate the gradient. Otherwise, use src.	bool	true (default), false	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src / dst	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

SqrtBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

Square

Square operation performs element-wise square operation with given tensor.

Operation Attributes

Square operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Square operation supports the following data type combinations.

Src	Dst
f32	f32
f16	f16
bf16	bf16

SquaredDifference

SquaredDifference operation performs element-wise subtraction operation with two given tensors applying multi-directional broadcast rules, after that each result of the subtraction is squared.

Before performing arithmetic operation, src_1 and src_2 are broadcasted if their shapes are different and `auto_broadcast` attributes is not none. Broadcasting is performed according to `auto_broadcast` value. After broadcasting SquaredDifference does the following with the input tensors:

$$dst_i = (src_1_i - src_2_i)^2$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>auto_broadcast</i>	Specifies rules used for auto-broadcasting of src tensors	string	none, numpy, (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src_1	Required
1	src_2	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

SquaredDifference operation supports the following data type combinations.

Src_1	Src_2	Dst
f32	f32	f32
bf16	bf16	bf16
f16	f16	f16

StaticReshape

StaticReshape operation changes dimensions of src tensor according to the specified shape. The volume of src is equal to dst, where volume is the product of dimensions. dst may have a different memory layout from src. StaticReshape operation is not guaranteed to return a view or a copy of src when dst is in-placed with the src. StaticReshape can be used where if shape is stored in a constant node or available during graph building stage. Then shape can be passed via shape attribute.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>shape</i>	Specifies rules used for auto-broadcasting of src tensors	string	none, numpy (default)	Required
<i>special_zero</i>	Controls how zero values in shape are interpreted	bool	true, false	Required

@note *shape*: dimension -1 means that this dimension is calculated to keep the same overall elements count as the src tensor. That case that more than one -1 in the shape is not supported.

@note *special_zero*: if false, 0 in the shape is interpreted as-is (for example a zero-dimension tensor); if true, then all 0s in shape implies the copying of corresponding dimensions from src into dst.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

StaticReshape operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

StaticTranspose

StaticTranspose operation rearranges the dimensions of `src` with respect to the permutation described by `order`. `dst` may have a different memory layout from `src`. StaticTranspose operation is not guaranteed to return a view or a copy of `src` when `dst` is in-placed with the `src`.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>order</i>	Specifies permutation to be applied on <code>src</code>	s64	A s64 list containing the element in the range of [-N, N-1], negative value means counting from last axis	Required

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	<code>src</code>	Required

Outputs

Index	Argument Name	Required or Optional
0	<code>dst</code>	Required

Supported Data Types

StaticTranspose operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

Subtract

Subtract operation performs element-wise subtraction operation with two given tensors applying multi-directional broadcast rules.

$$\text{dst}(\bar{x}) = \text{src}_0(\bar{x}) - \text{src}_1(\bar{x})$$

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>auto_broadcast</i>	Specifies rules used for auto-broadcasting of src tensors	string	none, numpy, (default)	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src_0	Required
1	src_1	Required

@note Both src shapes should match and no auto-broadcasting is allowed if `auto_broadcast` attributes is none. `src_0` and `src_1` shapes can be different and auto-broadcasting is allowed if `auto_broadcast` attributes is numpy. Broadcasting is performed according to `auto_broadcast` value.

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Subtract operation supports the following data type combinations.

Source0/1	Destination
f32	f32
bf16	bf16
f16	f16

Tanh

Tanh operation applies following formula on every element of src tensor (the variable names follow the standard *Conventions*):

$$\text{dst} = \tanh(\text{src})$$

Operation Attributes

Tanh operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

Tanh operation supports the following data type combinations.

Src	Dst
f32	f32
bf16	bf16
f16	f16

TanhBackward

TanhBackward operation computes gradient for Tanh.

Operation Attributes

Attribute Name	Description	Value Type	Supported Values	Required or Optional
<i>use_dst</i>	If true, use dst of Tanh operation to calculate the gradient. Otherwise, use src.	bool	true (default), false	Optional

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src / dst	Required
1	diff_dst	Required

Outputs

Index	Argument Name	Required or Optional
0	diff_src	Required

Supported Data Types

TanhBackward operation supports the following data type combinations.

Src	Diff_dst	Diff_src
f32	f32	f32
f16	f16	f16
bf16	bf16	bf16

TypeCast

TypeCast operation performs element-wise cast from input data type to the data type given by output tensor. It requires that src and dst have the same shape and layout. Rounding to nearest even will be used during cast.

Operation Attributes

TypeCast operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Required

Outputs

Index	Argument Name	Required or Optional
0	dst	Required

Supported Data Types

TypeCast operation supports the following data type combinations.

Src	Dst
bf16, f16	f32
f32	bf16, f16

@note This operation is to support *mixed precision* computation.

Wildcard

Wildcard operation is used to represent any compute logic and help construct graph. Typically the operation can support mapping any framework ops which are not supported by the library implementation. It's useful to make the graph completed or connected.

Operation Attributes

Wildcard operation does not support any attribute.

Execution Arguments

The inputs and outputs must be provided according to the below index order when constructing an operation.

Inputs

Index	Argument Name	Required or Optional
0	src	Optional

Outputs

Index	Argument Name	Required or Optional
0	dst	Optional

@note WildCard operation can accept arbitrary number of inputs or outputs.

Supported Data Types

Wildcard operation supports arbitrary data type combinations.

5.7 Open Source Implementation

Intel has published an [open source implementation](#) with the Apache license.

5.8 Implementation Notes

This specification provides high-level descriptions for oneDNN operations and does not cover all the implementation-specific details of the [open source implementation](#). Specifically, it does not cover highly-optimized memory formats and integration with profiling tools, etc. This is done intentionally to improve specification portability. Code that uses API defined in this specification is expected to be portable across open source implementation and any potential other implementations of this specification to a reasonable extent.

In the future this section will be extended with more details on how different implementations of this specification should cooperate and co-exist.

5.9 Testing

Intel's binary distribution of oneDNN contains example code that you can be used to test library functionality. The [open source implementation](#) includes a comprehensive test suite. Consult the [README](#) for directions.

6.1 Introduction

The oneAPI Collective Communications Library (oneCCL) provides primitives for the communication patterns that occur in deep learning applications. oneCCL supports both scale-up for platforms with multiple oneAPI devices and scale-out for clusters with multiple compute nodes.

oneCCL supports the following communication patterns used in deep learning (DL) algorithms:

- allgatherv
- allreduce
- alltoallv
- broadcast
- reduce
- reduce_scatter

oneCCL exposes controls over additional optimizations and capabilities such as:

- Prioritization for communication operations
- Persistent communication operations (enables decoupling one-time initialization and repetitive execution)

6.2 Namespaces

This section describes the oneCCL namespace conventions.

6.2.1 oneapi::ccl namespace

The `oneapi::ccl` namespace shall contain public identifiers defined by the library.

6.2.2 ccl namespace

The alternative `ccl` namespace shall be considered an alias for the `oneapi::ccl` namespace.

6.3 Current Version of this oneCCL Specification

This is the oneCCL specification version 1.0.

6.4 Definitions

6.4.1 oneCCL Concepts

oneCCL specification defines the following list of concepts:

- *Device*
- *Context*
- *Key-Value Store*
- *Communicator*
- *Stream*
- *Event*
- *Operation Attributes*

Device

Note: Here and below, a native device/context/stream/event are defined in the scope of SYCL device runtime

```
using native_device_type = sycl::device;
using native_context_type = sycl::context;
using native_stream_type = sycl::queue;
using native_event_type = sycl::event;
```

oneCCL specification defines `device` as an abstraction of a computational device: a CPU, a specific GPU card in the system, or any other device participating in a communication operation. `device` corresponds to the communicator's rank (addressable entity in a communication operation).

oneCCL specification defines the way to create an instance of the `device` class with a native object (`native_device_type`) and without a native object (corresponds to the host).

Creating a new device object:

```
device ccl::create_device(native_device_type& native_device);

device ccl::create_device();
```

native_device the existing native device object

return device a device object

device class shall provide ability to retrieve a native object.

Retrieving a native device object:

```
native_device_type device::get_native();
```

return native_device_type

a native device object

shall throw exception if a device object does not wrap the native object

Context

oneCCL specification defines `context` as an abstraction of a computational devices context that is responsible for managing resources and for executing of communication operations on one or more devices specified in the context.

oneCCL specification defines the way to create an instance of the `context` class with a native object (`native_context_type`) and without a native object.

Creating a new context object:

```
context ccl::create_context(native_context_type& native_context);
context ccl::create_context();
```

native_context the existing native context object

return context a context object

`context` class shall provide ability to retrieve a native object.

Retrieving a native context object:

```
native_context_type context::get_native();
```

return native_context_type

a native context object

shall throw exception if a context object does not wrap the native object

Key-Value Store

`kvs_interface` defines the key-value store (KVS) interface to be used to establish connection between ranks during the creation of oneCCL communicator. The interface shall include blocking `get` and `set` methods.

Getting a record from the key-value store:

```
virtual vector_class<char> kvs_interface::get(
    const string_class& key) = 0;
```

key the key of value to be retrieved

return vector_class<char> the value associated with the given key

Note: `get` operation with a non-existing key shall return empty result

Saving a record in the key-value store:

```
void kvs_interface::set(
    const string_class& key,
    const vector_class<char>& data) = 0;
```

key the key at which the value should be stored

data the value that should be associated with the given key

Note: set operation with empty data shall remove a record from the key-value store

oneCCL specification defines `kvs` class as a built-in KVS provided by oneCCL.

```
class kvs : public kvs_interface {
public:
    static constexpr size_t address_max_size = 256;
    using address_type = array_class<char, address_max_size>;

    ~kvs() override;

    address_type get_address() const;

    vector_class<char> get(
        const string_class& key) override;

    void set(
        const string_class& key,
        const vector_class<char>& data) override;
}
```

Retrieving an address of built-in key-value store:

```
kvs::address_type kvs::get_address() const;
```

return kvs::address_type

the address of the key-value store

should be retrieved from the main built-in KVS and distributed to other processes for the built-in KVS creation

Creating a main built-in key-value store. Its address should be distributed using an out-of-band communication mechanism and be used to create key-value stores on other ranks:

```
shared_ptr_class<kvs> ccl::create_main_kvs();
```

return shared_ptr_class<kvs> the main key-value store object

Creating a new key-value store from main kvs address:

```
shared_ptr_class<kvs> ccl::create_kvs(const kvs::address_type& addr);
```

addr the address of the main kvs

return shared_ptr_class<kvs> key-value store object

Communicator

oneCCL specification defines `communicator` class that describes a group of communicating ranks, where a rank is an addressable entity in a communication operation and corresponds to single oneCCL device.

`communicator` defines communication operations on memory buffers between homogeneous oneCCL devices, that is, all oneCCL devices either wrap native device objects of the same type (for example CPUs only or GPUs only) or do not wrap native objects.

Each process may correspond to multiple ranks.

Note: Support for multiple ranks per process is optional

Creating a new communicator(s) with user-supplied communicator size, rank-to-device mapping/rank, context and kvs:

Note: If device and context objects are omitted, then they are created with `ccl::create_device()` or `ccl::create_context()` functions without native objects

```
vector_class<communicator> ccl::create_communicators(
    int size,
    const map_class<int, device>& rank_device_map,
    const context& context,
    shared_ptr_class<kvs_interface> kvs);

communicator ccl::create_communicator(
    int size,
    int rank,
    shared_ptr_class<kvs_interface> kvs);
```

size user-supplied total number of ranks

rank_device_map user-supplied mapping of local ranks on devices

rank user-supplied local rank

context device context

kvs key-value store for ranks wire-up

return vector_class<communicator> / communicator a vector of communicator objects / a communicator object

`communicator` shall provide methods to retrieve the rank, the device, and the context that correspond to the communicator object as well as the total number of ranks in the communicator.

Retrieving the rank in a communicator:

```
int communicator::rank() const;
```

return int the rank that corresponds to the communicator object

Retrieving the total number of ranks in a communicator:

```
int communicator::size() const;
```

return int the total number of the ranks

Retrieving an underlying device, which was used as communicator construction argument:

```
device communicator::get_device() const;
```

return device the device that corresponds to the communicator object

Retrieving an underlying context, which was used as communicator construction argument:

```
context communicator::get_context() const;
```

return context the context that corresponds to the communicator object

Note: See also: *Collective Operations*

Stream

oneCCL specification defines `stream` as an abstraction that encapsulates execution context for `communicator` communication operations.

Stream shall be passed to `communicator` communication operation.

oneCCL specification defines the way to create an instance of the `stream` class with a native object (`native_stream_type`) and without a native object.

Creating a new stream object:

```
stream ccl::create_stream(native_stream_type& native_stream);
stream ccl::create_stream();
```

native_stream the existing native stream object

return stream a stream object

`stream` class shall provide ability to retrieve a native object.

Retrieving a native stream object:

```
native_stream_type stream::get_native();
```

return native_stream_type

a native stream object

shall throw exception if a `stream` object does not wrap the native object

Event

oneCCL specification defines `event` as an abstraction that encapsulates synchronization context for `communicator` communication operations.

Each communication operation of oneCCL shall return an event object for tracking the operation's progress. A vector of events may be passed to the `communicator` communication operation to designate input dependencies for the operation.

Note: Support for handling of input events is optional

oneCCL specification defines the way to create an instance of the `event` class with a native object (`native_event_type`).

Creating a new event object:

```
event ccl::create_event(native_event_type& native_event);
```

native_event the existing native event object

return event an event object

event class shall provide ability to retrieve a native object.

Retrieving a native event object:

```
native_event_type event::get_native();
```

return native_event_type

a native event object

shall throw exception if an event object does not wrap the native object

Note: See also: *Operation Progress Tracking*

Operation Attributes

Communication operation behavior may be controlled through operation attributes.

Operation Attributes

6.4.2 Communication Operations

This section covers communication operations defined by oneCCL specification.

Datatypes

oneCCL specification defines the following datatypes that may be used for communication operations:

```
enum class datatype : int
{
    int8           = /* unspecified */,
    uint8          = /* unspecified */,
    int16          = /* unspecified */,
    uint16         = /* unspecified */,
    int32          = /* unspecified */,
    uint32         = /* unspecified */,
    int64          = /* unspecified */,
    uint64         = /* unspecified */,

    float16       = /* unspecified */,
    float32       = /* unspecified */,
    float64       = /* unspecified */,
    bfloat16      = /* unspecified */,

    last_predefined = /* unspecified, equal to the largest of all the values above */
};
```

datatype::int8 8 bits signed integer
datatype::uint8 8 bits unsigned integer
datatype::int16 16 bits signed integer
datatype::uint16 16 bits unsigned integer
datatype::int32 32 bits signed integer
datatype::uint32 32 bits unsigned integer
datatype::int64 64 bits signed integer
datatype::uint64 64 bits unsigned integer
datatype::float16 16-bit/half-precision floating point
datatype::float32 32-bit/single-precision floating point
datatype::float64 64-bit/double-precision floating point
datatype::bfloat16 non-standard 16-bit floating point with 7-bit mantissa

Note: Support for `datatype::float16` is optional

Custom Datatypes

oneCCL specification defines the way to register and deregister a custom datatype using the `datatype_attr` attribute object.

The list of identifiers that may be used to fill an attribute object:

```
enum class datatype_attr_id {
    size = /* unspecified */
};
```

datatype_attr_id::size the size of the datatype in bytes

Creating a datatype attribute object, which may used to register custom datatype:

```
datatype_attr ccl::create_datatype_attr();
```

return datatype_attr an object containing attributes for the custom datatype

Registering a custom datatype to be used in communication operations:

```
datatype ccl::register_datatype(const datatype_attr& attr);
```

attr the datatype's attributes

return datatype the handle for the custom datatype

Deregistering a custom datatype:

```
void ccl::deregister_datatype(datatype dtype);
```

dtype the handle for the custom datatype

Retrieving a datatype size in bytes:

```
size_t ccl::get_datatype_size(datatype dtype);
```

dtype the datatype's handle

return size_t datatype size in bytes

Reductions

oneCCL specification defines the following reduction operations for *Allreduce*, *Reduce* and *ReduceScatter* collective operations:

```
enum class reduction
{
    sum      = /* unspecified */,
    prod     = /* unspecified */,
    min      = /* unspecified */,
    max      = /* unspecified */,
    custom   = /* unspecified */
};
```

reduction::sum elementwise summation

reduction::prod elementwise multiplication

reduction::min elementwise min

reduction::max elementwise max

reduction::custom

specify user-defined reduction operation

the actual reduction function must be passed through `reduction_fn` operation attribute

Operation Attributes

Collective Operations

oneCCL specification defines the following collective communication operations:

- *Allgather*
- *Allreduce*
- *Alltoallv*
- *Barrier*
- *Broadcast*
- *Reduce*
- *ReduceScatter*

These operations are collective, meaning that all participants (ranks) of oneCCL communicator should make a call. The order of collective operation calls should be the same across all ranks.

communicator shall provide the ability to perform communication operations either on host or device memory buffers depending on the device used to create the communicator. Additionally, communication operations shall accept an execution context (stream) and may accept a vector of events that the communication operation should depend on, that is, input dependencies. The output event object shall provide the ability to track the progress of the operation.

Note: Support for handling of input events is optional

BufferType is used below to define the C++ type of elements in data buffers (buf, send_buf and recv_buf) of communication operations. At least the following types shall be supported: [u]int{8/16/32/64}_t, float, double. The explicit datatype parameter shall be used to enable data types which cannot be inferred from the function arguments.

Note: See also: *Custom Datatypes*

The communication operation accepts a stream object. If a communicator is created from native_device_type, then the stream shall translate to native_stream_type created from the corresponding device.

The communication operation may accept attribute object. If that parameter is missed, then the default attribute object is used (default_<operation_name>_attr). The default attribute object shall be provided by the library.

Note: See also: *Operation Attributes*

If the arguments provided to a communication operation call do not comply to the requirements of the operation, the behavior is undefined unless it is specified otherwise.

Allgatherv

Allgatherv is a collective communication operation that collects data from all the ranks within a communicator into a single buffer. Different ranks may contribute segments of different sizes. The resulting data in the output buffer must be the same for each rank.

```

template<class BufferType>
event ccl::allgatherv(const BufferType* send_buf,
                    size_t send_count,
                    BufferType* recv_buf,
                    const vector_class<size_t>& recv_counts,
                    const communicator& comm,
                    const stream& stream,
                    const allgatherv_attr& attr = default_allgatherv_attr,
                    const vector_class<event>& deps = {});

event ccl::allgatherv(const void* send_buf,
                    size_t send_count,
                    void* recv_buf,
                    const vector_class<size_t>& recv_counts,
                    datatype dtype,
                    const communicator& comm,
                    const stream& stream,
                    const allgatherv_attr& attr = default_allgatherv_attr,
                    const vector_class<event>& deps = {});

```

send_buf the buffer with send_count elements of BufferType that stores local data to be gathered

send_count the number of elements of type BufferType in send_buf

recv_buf [out] the buffer to store the gathered result, must be large enough to hold values from all ranks

recv_counts

an array with the number of elements of type `BufferType` to be received from each rank
 the array's size must be equal to the number of ranks
 the values in the array are expected to be the same for all ranks
 the value at the position of the caller's rank must be equal to `send_count`

dtype

the datatype of elements in `send_buf` and `recv_buf`
 must be skipped if `BufferType` can be inferred
 otherwise must be passed explicitly

comm the communicator that defines a group of ranks for the operation

stream the stream associated with the operation

attr optional attributes to customize the operation

deps an optional vector of the events that the operation should depend on

return event an object to track the progress of the operation

Allreduce

Allreduce is a collective communication operation that performs the global reduction operation on values from all ranks of communicator and distributes the result back to all ranks.

```

template <class BufferType>
event ccl::allreduce(const BufferType* send_buf,
                    BufferType* recv_buf,
                    size_t count,
                    reduction rtype,
                    const communicator& comm,
                    const stream& stream,
                    const allreduce_attr& attr = default_allreduce_attr,
                    const vector_class<event>& deps = {});

event ccl::allreduce(const void* send_buf,
                    void* recv_buf,
                    size_t count,
                    reduction rtype,
                    datatype dtype,
                    const communicator& comm,
                    const stream& stream,
                    const allreduce_attr& attr = default_allreduce_attr,
                    const vector_class<event>& deps = {});

```

send_buf the buffer with `count` elements of `BufferType` that stores local data to be reduced

recv_buf [out] the buffer to store the reduced result, must have the same dimension as `send_buf`

count the number of elements of type `BufferType` in `send_buf` and `recv_buf`

rtype the type of the reduction operation to be applied

dtype

the datatype of elements in `send_buf` and `recv_buf`

must be skipped if `BufferType` can be inferred
 otherwise must be passed explicitly

comm the communicator that defines a group of ranks for the operation

stream the stream associated with the operation

attr optional attributes to customize the operation

deps an optional vector of the events that the operation should depend on

return event an object to track the progress of the operation

Alltoallv

Alltoall is a collective communication operation in which each rank sends separate blocks of data to each rank. Block sizes may differ. The *j*-th block of send buffer sent from the *i*-th rank is received by the *j*-th rank and is placed in the *i*-th block of receive buffer.

```
template <class BufferType>
event ccl::alltoallv(const BufferType* send_buf,
                   const vector_class<size_t>& send_counts,
                   BufferType* recv_buf,
                   const vector_class<size_t>& recv_counts,
                   const communicator& comm,
                   const stream& stream,
                   const alltoallv_attr& attr = default_alltoallv_attr,
                   const vector_class<event>& deps = {});

event ccl::alltoallv(const void* send_buf,
                   const vector_class<size_t>& send_counts,
                   void* recv_buf,
                   const vector_class<size_t>& recv_counts,
                   datatype dtype,
                   const communicator& comm,
                   const stream& stream,
                   const alltoallv_attr& attr = default_alltoallv_attr,
                   const vector_class<event>& deps = {});
```

send_buf the buffer with elements of `BufferType` that stores local blocks to be sent to each rank

send_counts

an array with number of elements of type `BufferType` in the blocks sent for each rank

the array's size must be equal to the number of ranks

the values at the position of the caller's rank in `send_counts` and `recv_counts` must be equal

recv_buf [out] the buffer to store the received result, must be large enough to hold blocks from all ranks

recv_counts

an array with number of elements of type `BufferType` in the blocks received from each rank

the array's size must be equal to the number of ranks

the values at the position of the caller's rank in `send_counts` and `recv_counts` must be equal

dtype

the datatype of elements in `send_buf` and `recv_buf`

must be skipped if `BufferType` can be inferred
otherwise must be passed explicitly

comm the communicator that defines a group of ranks for the operation

stream the stream associated with the operation

attr optional attributes to customize the operation

deps an optional vector of the events that the operation should depend on

return event an object to track the progress of the operation

Barrier

Barrier synchronization is performed across all ranks of the communicator and it is completed only after all the ranks in the communicator have called it.

```
event ccl::barrier(const communicator& comm,
                  const stream& stream,
                  const barrier_attr& attr = default_barrier_attr,
                  const vector_class<event>& deps = {});
```

comm the communicator that defines a group of ranks for the operation

stream the stream associated with the operation

attr optional attributes to customize the operation

deps an optional vector of the events that the operation should depend on

return event an object to track the progress of the operation

Broadcast

Broadcast is a collective communication operation that broadcasts data from one rank of communicator (denoted as root) to all other ranks.

```
template <class BufferType>
event ccl::broadcast(BufferType* buf,
                    size_t count,
                    int root,
                    const communicator& comm,
                    const stream& stream,
                    const broadcast_attr& attr = default_broadcast_attr,
                    const vector_class<event>& deps = {});

event ccl::broadcast(void* buf,
                    size_t count,
                    datatype dtype,
                    int root,
                    const communicator& comm,
                    const stream& stream,
                    const broadcast_attr& attr = default_broadcast_attr,
                    const vector_class<event>& deps = {});
```

buf [in,out]

the buffer with `count` elements of `BufferType`
serves as `send_buf` for root and as `recv_buf` for other ranks

count the number of elements of type `BufferType` in `buf`

root the rank that broadcasts `buf`

dtype

the datatype of elements in `buf`
must be skipped if `BufferType` can be inferred
otherwise must be passed explicitly

comm the communicator that defines a group of ranks for the operation

stream the stream associated with the operation

attr optional attributes to customize the operation

deps an optional vector of the events that the operation should depend on

return event an object to track the progress of the operation

Reduce

Reduce is a collective communication operation that performs the global reduction operation on values from all ranks of the communicator and returns the result to the root rank.

```
template <class BufferType>
event ccl::reduce(const BufferType* send_buf,
                 BufferType* recv_buf,
                 size_t count,
                 reduction rtype,
                 int root,
                 const communicator& comm,
                 const stream& stream,
                 const reduce_attr& attr = default_reduce_attr,
                 const vector_class<event>& deps = {});

event ccl::reduce(const void* send_buf,
                 void* recv_buf,
                 size_t count,
                 datatype dtype,
                 reduction rtype,
                 int root,
                 const communicator& comm,
                 const stream& stream,
                 const reduce_attr& attr = default_reduce_attr,
                 const vector_class<event>& deps = {});
```

send_buf the buffer with `count` elements of `BufferType` that stores local data to be reduced

recv_buf [out]

the buffer to store the reduced result, must have the same dimension as `send_buf`.
Used by the root rank only, ignored by other ranks.

count the number of elements of type `BufferType` in `send_buf` and `recv_buf`

rtype the type of the reduction operation to be applied

root the rank that gets the result of the reduction

dtype

the datatype of elements in `send_buf` and `recv_buf`
 must be skipped if `BufferType` can be inferred
 otherwise must be passed explicitly

comm the communicator that defines a group of ranks for the operation

stream the stream associated with the operation

attr optional attributes to customize the operation

deps an optional vector of the events that the operation should depend on

return event an object to track the progress of the operation

ReduceScatter

Reduce-scatter is a collective communication operation that performs the global reduction operation on values from all ranks of the communicator and scatters the result in blocks back to all ranks.

```

template <class BufferType>
event ccl::reduce_scatter(const BufferType* send_buf,
                        BufferType* recv_buf,
                        size_t recv_count,
                        reduction rtype,
                        const communicator& comm,
                        const stream& stream,
                        const reduce_scatter_attr& attr = default_reduce_scatter_attr,
                        const vector_class<event>& deps = {});

event ccl::reduce_scatter(const void* send_buf,
                        void* recv_buf,
                        size_t recv_count,
                        datatype dtype,
                        reduction rtype,
                        const communicator& comm,
                        const stream& stream,
                        const reduce_scatter_attr& attr = default_reduce_scatter_attr,
                        const vector_class<event>& deps = {});

```

send_buf the buffer with `comm_size * count` elements of `BufferType` that stores local data to be reduced

recv_buf [out] the buffer to store the result block containing `recv_count` elements of type `BufferType`

recv_count the number of elements of type `BufferType` in the received block

rtype the type of the reduction operation to be applied

dtype

the datatype of elements in `send_buf` and `recv_buf`
 must be skipped if `BufferType` can be inferred
 otherwise must be passed explicitly

comm the communicator that defines a group of ranks for the operation

stream the stream associated with the operation

attr optional attributes to customize the operation

deps an optional vector of the events that the operation should depend on

return event an object to track the progress of the operation

Note: See also:

- *Communicator*
 - *Stream*
 - *Event*
 - *Operation Progress Tracking*
-

Operation Attributes

oneCCL specification defines communication operation attributes that serve as modifiers of an operation's behavior. Optionally, they may be passed to the corresponding communication operations.

oneCCL specification defines the following operation attribute classes:

- `allgatherv_attr`
- `allreduce_attr`
- `alltoallv_attr`
- `barrier_attr`
- `broadcast_attr`
- `reduce_attr`
- `reduce_scatter_attr`

oneCCL specification defines attribute identifiers that may be used to fill operation attribute objects.

The list of common attribute identifiers that may be used for any communication operation:

```
enum class operation_attr_id {
    priority      = /* unspecified */,
    to_cache     = /* unspecified */,
    synchronous   = /* unspecified */,
    match_id     = /* unspecified */

    last_value   = /* unspecified, equal to the largest of all the values above */
};
```

operation_attr_id::priority the priority of the communication operation

operation_attr_id::to_cache

persistent/non-persistent communication operation
should be used in conjunction with `match_id`

operation_attr_id::synchronous synchronous/asynchronous communication operation

operation_attr_id::match_id

the unique identifier of the operation
in conjunction with `to_cache`, it enables the caching of the communication operation

The communication operation specific attribute identifiers may extend the list of common identifiers.

The list of attribute identifiers that may be used for *Allreduce*, *Reduce* and *ReduceScatter* collective operations:

```
enum class allreduce_attr_id {
    reduction_fn = /* unspecified */
};

enum class reduce_attr_id {
    reduction_fn = /* unspecified */
};

enum class reduce_scatter_attr_id {
    reduction_fn = /* unspecified */
};
```

`allreduce_attr_id::reduction_fn` / `reduce_attr_id::reduction_fn` / `reduce_scatter_attr_id::reduction_fn` a function pointer for the custom reduction operation that follows the signature:

```
typedef void (*reduction_fn)
(
    const void*,      /* in_buf   */
    size_t,           /* in_count */
    void*,            /* inout_buf */
    size_t*,          /* out_count */
    datatype,         /* datatype */
    const fn_context* /* context  */
);

typedef struct {
    const char* match_id;
    const size_t offset;
} fn_context;
```

Creating an operation attribute object, which may be used in a corresponding communication operation:

```
template <class OpAttrType>
OpAttrType ccl::create_operation_attr();
```

return OpAttrType an object to hold attributes for a specific communication operation

The operation attribute classes shall provide `get` and `set` methods for getting and setting of values with specific attribute identifiers.

Operation Progress Tracking

oneCCL communication operation shall return an event object to be used for tracking the operation's progress.

The `event` class shall provide the ability to wait for completion of an operation in a blocking manner, the ability to check the completion status in a non-blocking manner, and the ability to retrieve the underlying native object that is signaled when the operation completes.

Event

Waiting for the completion of an operation in a blocking manner:

```
void event::wait();
```

Checking for the completion of an operation in a non-blocking manner:

```
bool event::test();
```

return bool `true` if the operation has been completed `false` if the operation has not been completed

Retrieving a native object that is signaled when the operation completes:

```
native_event_type event::get_native();
```

return native_event_type

a native object that is signaled when the operation completes

shall throw an exception if an event object does not wrap the native object

6.4.3 Error handling

oneCCL error handling relies on the mechanism of C++ exceptions. If an error occurs, it shall be propagated at the point of a function call where it is caught using standard C++ error handling mechanism.

Exception classification

Exception classification in oneCCL is aligned with C++ Standard Library classification. oneCCL introduces class that defines the base class in the hierarchy of oneCCL exception classes. All oneCCL routines throw exceptions inherited from this base class.

In the hierarchy of oneCCL exceptions, `ccl::exception` is the base class inherited from `std::exception` class. All other oneCCL exception classes are derived from this base class.

This specification does not require implementations to perform error-checking. However, if an implementation does provide error-checking, it shall use the following exception classes. Additional implementation-specific exception classes can be used for exceptional conditions not fitting any of these classes.

Common exceptions

Exception class	Description
<code>ccl::exception</code>	Reports general unspecified error
<code>ccl::invalid_argument</code>	Reports an error when arguments to the operation were rejected
<code>ccl::host_bad_alloc</code>	Reports an error that occurred during memory allocation on the host
<code>ccl::unimplemented</code>	Reports an error when the requested operation is not implemented
<code>ccl::unsupported</code>	Reports an error when the requested operation is not supported

6.5 Programming Model

6.5.1 Generic Workflow

Below is a generic workflow with oneCCL API

1. Create a main built-in key-value store. Its address should be distributed using an out-of-band communication mechanism and be used to create key-value stores on other processes:

```
using namespace std;

/* for example use MPI as an out-of-band communication mechanism */

int mpi_rank, mpi_size;

MPI_Init(&argc, &argv);
MPI_Comm_rank(MPI_COMM_WORLD, &mpi_rank);
MPI_Comm_size(MPI_COMM_WORLD, &mpi_size);

ccl::shared_ptr_class<ccl::kvs> kvs;
ccl::kvs::address_type kvs_addr;

if (mpi_rank == 0) {
    kvs = ccl::create_main_kvs();
    kvs_addr = kvs->get_address();
    MPI_Bcast((void*)kvs_addr.data(), ccl::kvs::address_max_size, MPI_BYTE, 0, MPI_COMM_
↪WORLD);
}
else {
    MPI_Bcast((void*)kvs_addr.data(), ccl::kvs::address_max_size, MPI_BYTE, 0, MPI_COMM_
↪WORLD);
    kvs = ccl::create_kvs(kvs_addr);
}
```

2. Create communicator(s):

```
/* host communications */
auto comm = ccl::create_communicator(mpi_size, mpi_rank, kvs);
```

```

/* SYCL devices communications, for example with multiple devices per process */

/* sycl_context -> sycl::context */
/* sycl_devices -> vector<sycl::device> */
/* sycl_queues -> vector<sycl::queue> */

/* create ccl::context object from sycl::context object */
auto ccl_context = ccl::create_context(sycl_context);

/* create ccl::device objects from sycl::device objects */
vector<ccl::device> ccl_devices;
for (size_t idx = 0; idx < sycl_devices.size(); idx++) {
    ccl_devices.push_back(ccl::create_device(sycl_devices[idx]));
}

map<int, ccl::device> r2d_map;
for (auto& dev : ccl_devices) {
    int rank = /* generate a globally unique rank for a specific device */
    r2d_map[rank] = dev;
}

/* create ccl::stream objects from sycl::queue objects */
vector<ccl::stream> ccl_streams;
for (size_t idx = 0; idx < sycl_queues.size(); idx++) {
    ccl_streams.push_back(ccl::create_stream(sycl_queues[idx]));
}

auto comms = ccl::create_communicators(mpi_size * r2d_map.size(),
                                       r2d_map,
                                       ccl_context,
                                       kvs);

```

- Execute a communication operation of choice on the communicator(s):

```

/* host communications */
allreduce(..., comm).wait();

```

```

/* SYCL devices communications */
vector<ccl::event> events;
for (auto& comm : comms) {
    events.push_back(allreduce(..., comm, ccl_streams[comm.rank()]));
}

for (auto& e : events) {
    e.wait();
}

```

LEVEL ZERO

The oneAPI Level Zero (Level Zero) provides low-level direct-to-metal interfaces that are tailored to the devices in a oneAPI platform. Level Zero supports broader language features such as function pointers, virtual functions, unified memory, and I/O capabilities while also providing fine-grain explicit controls needed by higher-level runtime APIs including:

- Device discovery
- Memory allocation
- Peer-to-peer communication
- Inter-process sharing
- Kernel submission
- Asynchronous execution and scheduling
- Synchronization primitives
- Metrics reporting

The API architecture exposes both physical and logical abstractions of the underlying oneAPI platform devices and their capabilities. The device, sub-device, and memory are exposed at a physical level while command queues, events, and synchronization methods are defined as logical entities. All logical entities are bound to device-level physical capabilities. The API provides a scheduling model that is tailored to multiple uses including a low-latency submission model to the devices as well as one that is tailored to the construction and submission of work across simultaneous host threads. While heavily influenced by other low-level APIs, such as OpenCL, Level Zero is designed to evolve independently. While heavily influenced by GPU architecture, Level Zero is supportable across different oneAPI compute device architectures, such as FPGAs.

7.1 Detailed API Descriptions

The detailed specification can be found online in the [specification](#).

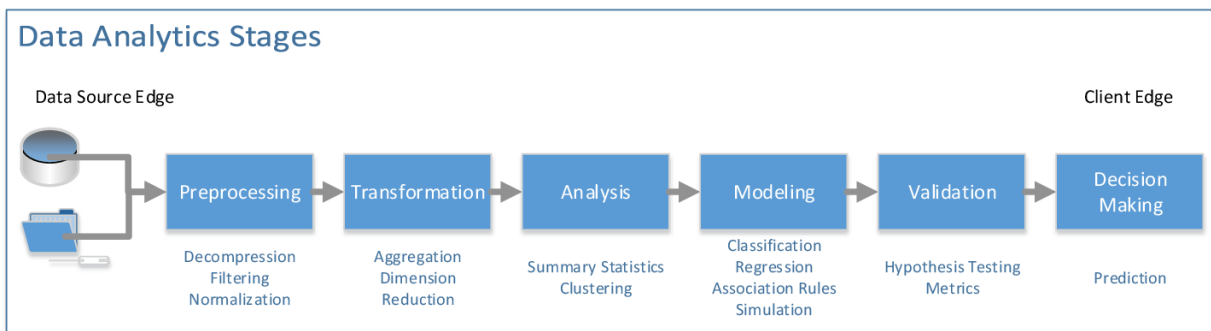

This document specifies requirements for implementations of oneAPI Data Analytics Library (oneDAL).

oneDAL is a library that helps speed up big data analysis by providing highly optimized algorithmic building blocks for all stages of data analytics (preprocessing, transformation, analysis, modeling, validation, and decision making) in batch, online, and distributed processing modes of computation. The current version of oneDAL provides Data Parallel C++ (DPC++) API extensions to the traditional C++ interface.

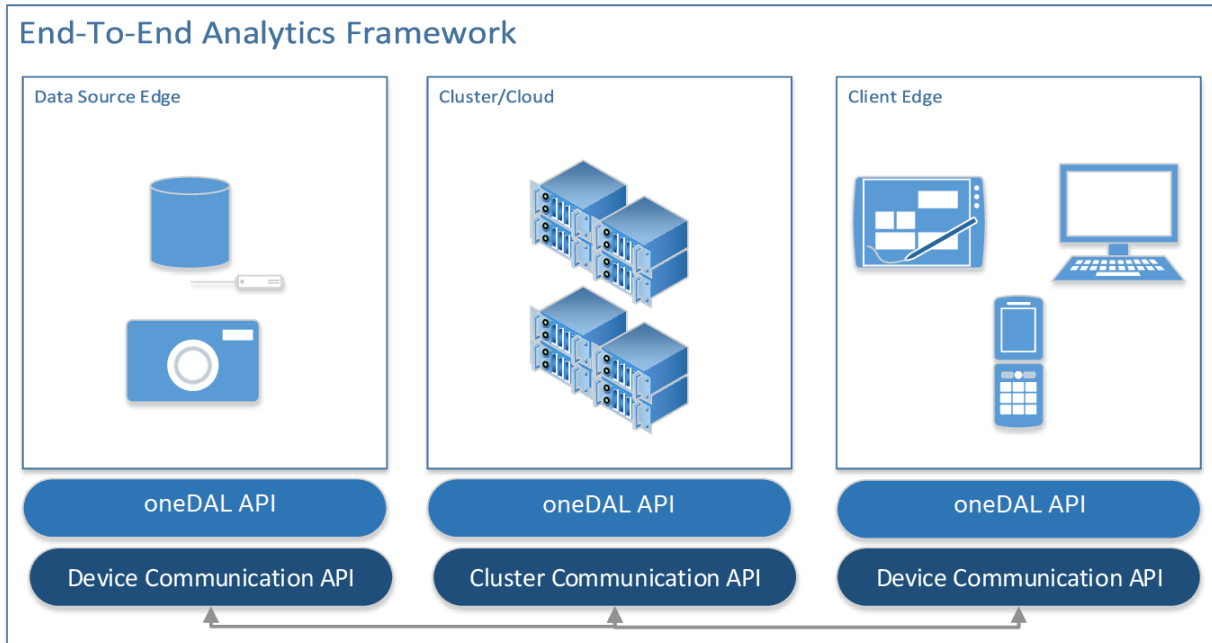

For general information, visit [oneDAL GitHub*](#) page.

8.1 Introduction

oneAPI Data Analytics Library (oneDAL) is a library that provides building blocks covering all stages of data analytics: data acquisition from a data source, preprocessing, transformation, data mining, modeling, validation, and decision making.

oneDAL supports the concept of the end-to-end analytics when some of data analytics stages are performed on the edge devices (close to where the data is generated and where it is finally consumed). Specifically, oneDAL Application Programming Interfaces (APIs) are agnostic about a particular cross-device communication technology and, therefore, can be used within different end-to-end analytics frameworks.

oneDAL consists of the following major components:

- The *Data Management* component includes classes and utilities for data acquisition, initial preprocessing and normalization, for data conversion into numeric formats (performed by one of supported Data Sources), and for model representation.
- The *Algorithms* component consists of classes that implement algorithms for data analysis (data mining) and data modeling (training and prediction). These algorithms include clustering, classification, regression, and recommendation algorithms. Algorithms support the following computation modes:
 - *Batch processing*: algorithms work with the entire data set to produce the final result
 - *Online processing*: algorithms process a data set in blocks streamed into the device's memory
 - *Distributed processing*: algorithms operate on a data set distributed across several devices (compute nodes)
 Distributed algorithms in oneDAL are abstracted from underlying cross-device communication technology, which enables use of the library in a variety of multi-device computing and data transfer scenarios.

Depending on the usage, algorithms operate both on actual data (data set) and data models:

- Analysis algorithms typically operate on data sets.
- Training algorithms typically operate on a data set to train an appropriate data model.
- Prediction algorithms typically work with the trained data model and with a working data set.
- The **Utilities** component includes auxiliary functionality intended to be used for design of classes and implementation of methods such as memory allocators or type traits.
- The **Miscellaneous** component includes functionality intended to be used by oneDAL algorithms and applications for algorithm customization and optimization on various stages of the analytical pipeline. Examples of such algorithms include solvers and random number generators.

Classes in Data Management, Algorithms, Utilities, and Miscellaneous components cover the most important usage scenarios and allow seamless implementation of complex data analytics workflows through direct API calls. At the same time, the library is an object-oriented framework that helps customize the API by redefining particular classes and methods of the library.

8.2 Glossary

8.2.1 Machine learning terms

Categorical feature A *feature* with a discrete domain. Can be *nominal* or *ordinal*.

Synonyms: discrete feature, qualitative feature

Classification A *supervised machine learning problem* of assigning *labels* to *feature vectors*.

Examples: predict what type of object is on the picture (a dog or a cat?), predict whether or not an email is spam

Clustering An *unsupervised machine learning problem* of grouping *feature vectors* into bunches, which are usually encoded as *nominal* values.

Example: find big star clusters in the space images

Continuous feature A *feature* with values in a domain of real numbers. Can be *interval* or *ratio*

Synonyms: quantitative feature, numerical feature

Examples: a person's height, the price of the house

CSV file A comma-separated values file (csv) is a type of a text file. Each line in a CSV file is a record containing fields that are separated by the delimiter. Fields can be of a numerical or a text format. Text usually refers to categorical values. By default, the delimiter is a comma, but, generally, it can be any character. For more details, see.

Dataset A collection of *observations*.

Dimensionality reduction A problem of transforming a set of *feature vectors* from a high-dimensional space into a low-dimensional space while retaining meaningful properties of the original feature vectors.

Feature A particular property or quality of a real object or an event. Has a defined type and domain. In machine learning problems, features are considered as input variable that are independent from each other.

Synonyms: attribute, variable, input variable

Feature vector A vector that encodes information about real object, an event or a group of objects or events. Contains at least one *feature*.

Example: A rectangle can be described by two features: its width and height

Inference A process of applying a *trained model* to the *dataset* in order to predict *response* values based on input *feature vectors*.

Synonym: prediction

Inference set A *dataset* used at the *inference* stage. Usually without *responses*.

Interval feature A *continuous feature* with values that can be compared, added or subtracted, but cannot be multiplied or divided.

Examples: a time frame scale, a temperature in Celsius or Fahrenheit

Label A *response* with *categorical* or *ordinal* values. This is an output in *classification* and *clustering* problems.

Example: the spam-detection problem has a binary label indicating whether the email is spam or not

Model An entity that stores information necessary to run *inference* on a new *dataset*. Typically a result of a *training* process.

Example: in linear regression algorithm, the model contains weight values for each input feature and a single bias value

Nominal feature A *categorical feature* without ordering between values. Only equality operation is defined for nominal features.

Examples: a person's gender, color of a car

Observation A *feature vector* and zero or more *responses*.

Synonyms: instance, sample

Ordinal feature A *categorical feature* with defined operations of equality and ordering between values.

Example: student's grade

Outlier *Observation* which is significantly different from the other observations.

Ratio feature A *continuous feature* with defined operations of equality, comparison, addition, subtraction, multiplication, and division. Zero value element means the absence of any value.

Example: the height of a tower

Regression A *supervised machine learning problem* of assigning *continuous responses* for *feature vectors*.

Example: predict temperature based on weather conditions

Response A property of some real object or event which dependency from *feature vector* need to be defined in *supervised learning* problem. While a *feature* is an input in the machine learning problem, the response is one of the outputs can be made by the *model* on the *inference* stage.

Synonym: dependent variable

Supervised learning *Training* process that uses a *dataset* with information about dependencies between *features* and *responses*. The goal is to get a *model* of dependencies between input *feature vector* and *responses*.

Training A process of creating a *model* based on information extracted from a *training set*. Resulting *model* is selected in accordance with some quality criteria.

Training set A *dataset* used at the *training* stage to create a *model*.

Unsupervised learning *Training* process that uses a *training set* with no *responses*. The goal is to find hidden patterns inside *feature vectors* and dependencies between them.

8.2.2 oneDAL terms

Accessor A oneDAL concept for an object that provides access to the data of another object in the special *data format*. It abstracts data access from interface of an object and provides uniform access to the data stored in objects of different types.

Batch mode The computation mode for an algorithm in oneDAL, where all the data needed for computation is available at the start and fits the memory of the device on which the computations are performed.

Builder A oneDAL concept for an object that encapsulates the creation process of another object and enables its iterative creation.

Contiguous data Data that are stored as one contiguous memory block. One of the characteristics of a *data format*.

Data format Representation of the internal structure of the data.

Examples: data can be stored in array-of-structures or compressed-sparse-row format

Data layout A characteristic of *data format* which describes the order of elements in a *contiguous data* block.

Example: row-major format, where elements are stored row by row

Data type An attribute of data used by a compiler to store and access them. Includes size in bytes, encoding principles, and available operations (in terms of a programming language).

Examples: `int32_t`, `float`, `double`

Flat data A block of *contiguous homogeneous* data.

Getter A method that returns the value of the private member variable.

Example:

```
std::int64_t get_row_count() const;
```

Heterogeneous data Data which contain values either of different *data types* or different sets of operations defined on them. One of the characteristics of a *data format*.

Example: A *dataset* with 100 *observations* of three *interval features*. The first two features are of float32 *data type*, while the third one is of float64 data type.

Homogeneous data Data with values of single *data type* and the same set of available operations defined on them. One of the characteristics of a *data format*.

Example: A *dataset* with 100 *observations* of three *interval features*, each of type float32

Immutability The object is immutable if it is not possible to change its state after creation.

Metadata Information about logical and physical structure of an object. All possible combinations of metadata values present the full set of possible objects of a given type. Metadata do not expose information that is not a part of a type definition, e.g. implementation details.

Example: *table* object can contain three *nominal features* with 100 *observations* (logical part of metadata). This object can store data as sparse csr array and provides direct access to them (physical part)

Online mode The computation mode for an algorithm in oneDAL, where the data needed for computation becomes available in parts over time.

Reference-counted object A copy-constructible and copy-assignable oneDAL object which stores the number of references to the unique implementation. Both copy operations defined for this object are lightweight, which means that each time a new object is created, only the number of references is increased. An implementation is automatically freed when the number of references becomes equal to zero.

Setter A method that accepts the only parameter and assigns its value to the private member variable.

Example:

```
void set_row_count(std::int64_t row_count);
```

Table A oneDAL concept for a *dataset* that contains only numerical data, *categorical* or *continuous*. Serves as a transfer of data between user's application and computations inside oneDAL. Hides details of *data format* and generalizes access to the data.

Workload A problem of applying a oneDAL algorithm to a *dataset*.

8.2.3 Common oneAPI terms

API Application Programming Interface

DPC++ Data Parallel C++ (DPC++) is a high-level language designed for data parallel programming productivity. DPC++ is based on *SYCL** from the Khronos* Group to support data parallelism and heterogeneous programming.

Host/Device OpenCL [*OpenCLSpec*] refers to CPU that controls the connected GPU executing kernels.

JIT Just in Time Compilation — compilation during execution of a program.

Kernel Code written in OpenCL [*OpenCLSpec*] or *SYCL* and executed on a GPU device.

SPIR-V Standard Portable Intermediate Representation - V is a language for intermediate representation of compute kernels.

SYCL SYCL(TM) [*SYCLSpec*] — high-level programming model for OpenCL(TM) that enables code for heterogeneous processors to be written in a “single-source” style using completely standard C++.

8.3 Mathematical Notations

Notation	Definition
n or m	The number of <i>observations</i> in a <i>dataset</i> . Typically n is used, but sometimes m is required to distinguish two datasets, e.g., the <i>training set</i> and the <i>inference set</i> .
p or r	The number of features in a dataset. Typically p is used, but sometimes r is required to distinguish two datasets.
$a \times b$	The dimensionality of a matrix (dataset) has a rows (observations) and b columns (features).
$ A $	Depending on the context may be interpreted as follows: <ul style="list-style-type: none"> • If A is a set, this denotes its cardinality, i.e., the number of elements in the set A. • If A is a real number, this denotes an absolute value of A.
$\ x\ $	The L_2 -norm of a vector $x \in \mathbb{R}^d$, $\ x\ = \sqrt{x_1^2 + x_2^2 + \cdots + x_d^2}.$
$\text{sgn}(x)$	Sign function for $x \in \mathbb{R}$, $\text{sgn}(x) = \begin{cases} -1, & x < 0, \\ 0, & x = 0, \\ 1, & x > 0. \end{cases}$
x_i	In the description of an algorithm, this typically denotes the i -th <i>feature vector</i> in the training set.
x'_i	In the description of an algorithm, this typically denotes the i -th feature vector in the inference set.
y_i	In the description of an algorithm, this typically denotes the i -th <i>response</i> in the training set.
y'_i	In the description of an algorithm, this typically denotes the i -th response that needs to be predicted by the inference algorithm given the feature vector x'_i from the inference set.

8.4 Programming model

oneDAL primarily targets algorithms that are extensively used in data analytics. These algorithms typically have many parameters, i.e. knobs to control its internal behavior and produced result. In machine learning, those parameters are often referred as *meta-parameters* to distinguish them from the model parameters learned during the training. Some algorithms define a dozen meta-parameters, while others depend on another algorithm as, for example, the logistic regression training procedure depends on an optimization algorithm.

Besides meta-parameters, machine learning algorithms may have different *stages*, such as *training* and *inference*. Moreover, the stages of an algorithm may be implemented in a variety of *computational methods*. For instance, a linear regression model could be trained by solving a system of linear equations [Friedman17] or by applying an iterative optimization solver directly to the empirical risk function [Zhang04].

The same machine learning techniques are often applied for solving problems of different types. In the example with linear regression, the same mathematical model used for solving *regression* problem is generalized for solving a *classification* problem, for example, logistic regression. Such techniques differ only in few problem-specific aspects, but share the same subset of meta-parameters and have a common computational flow. oneDAL does not distinguish these techniques into different algorithms. Instead, from oneDAL perspective, the same algorithm may perform different *computational tasks*.

From computational perspective, algorithm implementation may rely on different *floating-point types*, such as `float`, `double` or `bfloat16`. Having a capability to specify what type is needed is important for the end user as their precision requirements vary depending on a workload.

To best tackle the mentioned challenges, each algorithm is decomposed into *descriptors* and *operations*.

8.4.1 End-to-end example

Below you can find a typical workflow of using oneDAL algorithm on GPU. The example is provided for *Principal Component Analysis algorithm (PCA)*.

The following steps depict how to:

- Read the data from CSV file
 - Run the training and inference operations for PCA
 - Access intermediate results obtained at the training stage
1. Include the following header that makes all oneDAL declarations available.

```
#include "oneapi/dal.hpp"

/* Standard library headers required by this example */
#include <cassert>
#include <iostream>
```

2. Create a SYCL* queue with the desired device selector. In this case, GPU selector is used:

```
const auto queue = sycl::queue{ sycl::gpu_selector{} };
```

3. Since all oneDAL declarations are in the `oneapi::dal` namespace, import all declarations from the `oneapi` namespace to use `dal` instead of `oneapi::dal` for brevity:

```
using namespace oneapi;
```

4. Use *CSV data source* to read the data from the CSV file into a *table*:

```
const auto data = dal::read<dal::table>(queue, dal::csv::data_source{"data.csv"});
```

5. Create a *PCA* descriptor, configure its parameters, and run the training algorithm on the data loaded from CSV.

```
const auto pca_desc = dal::pca::descriptor<float>
    .set_component_count(3)
    .set_deterministic(true);

const dal::pca::train_result train_res = dal::train(queue, pca_desc, data);
```

6. Print the learned eigenvectors:

```
const dal::table eigenvectors = train_res.get_eigenvectors();

const auto acc = dal::row_accessor<const float>{eigenvectors};
for (std::int64_t i = 0; i < eigenvectors.row_count(); i++) {

    /* Get i-th row from the table, the eigenvector stores pointer to USM */
    const dal::array<float> eigenvector = acc.pull(queue, {i, i + 1});
    assert(eigenvector.get_count() == eigenvectors.get_column_count());

    std::cout << i << "-th eigenvector: ";
    for (std::int64_t j = 0; j < eigenvector.get_count(); j++) {
        std::cout << eigenvector[j] << " ";
    }
    std::cout << std::endl;
}
```

7. Use the trained model for inference to reduce dimensionality of the data:

```
const dal::pca::model model = train_res.get_model();

const dal::table data_transformed =
    dal::infer(queue, pca_desc, data).get_transformed_data();

assert(data_transformed.column_count() == 3);
```

8.4.2 Descriptors

A **descriptor** is an object that represents an algorithm including all its meta-parameters, dependencies on other algorithms, floating-point types, computational methods and tasks. A descriptor serves as:

- A dispatching mechanism for *operations*. Based on a descriptor type, an operation executes a particular algorithm implementation.
- An aggregator of meta-parameters. It provides an interface for setting up meta-parameters at either compile-time or run-time.
- An object that stores the state of the algorithm. In the general case, a descriptor is a stateful object whose state changes after an operation is applied.

Each oneDAL algorithm has its own dedicated namespace, where the corresponding descriptor is defined (for more details, see *Namespaces*). Descriptor, in its turn, defines the following:

- **Template parameters.** A descriptor is allowed to have any number of template parameters, but shall support at least three:
 - Float is a *floating-point type* that the algorithm uses for computations. This parameter is defined first and has the `oneapi::dal::default_float_t` default value.
 - Method is a tag-type that specifies the *computational method*. This parameter is defined second and has the `method::by_default` default value.
 - Task is a tag-type that specifies the *computational task*. This parameter is defined third and has the `task::by_default` default value.
- **Properties.** A property is a run-time parameter that can be accessed by means of the corresponding *getter* and *setter* methods.

The following code sample shows the common structure of a descriptor's definition for an abstract algorithm. To define a particular algorithm, the following strings shall be substituted:

- %ALGORITHM% is the name of an algorithm and its namespace. All classes and structures related to that algorithm are defined within the namespace.
- %PROPERTY_NAME% and %PROPERTY_TYPE% are the name and the type of one of the algorithm's properties.

```
namespace oneapi::dal::%ALGORITHM% {
template <typename Float = default_float_t,
         typename Method = method::by_default,
         typename Task = task::by_default,
         /* more template parameters */>
class descriptor {
public:
    /* Constructor */
    descriptor(const %PROPERTY_TYPE%& %PROPERTY_NAME%,
              /* more properties */)

    /* Getter & Setter for the property called `PROPERTY_NAME` */
    descriptor& set_%PROPERTY_NAME%(%PROPERTY_TYPE% value);
    %PROPERTY_TYPE% get_%PROPERTY_NAME%() const;

    /* more properties */
};
} // namespace oneapi::dal::%ALGORITHM%
```

Each meta-parameter of an algorithm is mapped to a property that shall satisfy the following requirements:

- Properties are defined with getter and setter methods. The underlying class member variable that stores the property's value is never exposed in the descriptor interface.
- The getter returns the value of the underlying class member variable.
- The setter accepts only one parameter of the property's type and assigns it to the underlying class member variable.
- Most of the properties are preset with default values, others are initialized by passing the required parameters to the constructor.
- The setter returns a reference to the descriptor object to allow chaining calls as shown in the example below.

```

auto desc = descriptor{
    .set_property_name_1(value_1)
    .set_property_name_2(value_2)
    .set_property_name_3(value_3);

```

Floating-point Types

It is required for each algorithm to support at least one implementation-defined floating-point type. Other floating-point types are optional, for example `float`, `double`, `float16`, and `bfloat16`. It is up to a specific oneDAL implementation whether or not to support these types.

The floating-point type used as a default in descriptors is implementation-defined and shall be declared within the top-level namespace.

```

namespace oneapi::dal {
    using default_float_t = /* implementation defined */;
} // namespace oneapi::dal

```

Computational Methods

The supported computational methods are declared within the `%ALGORITHM%::method` namespace using tag-types. Algorithm shall support at least one method and declare the `by_default` type alias that refers to one of the methods as shown in the example below.

```

namespace oneapi::dal::%ALGORITHM% {
    namespace method {
        struct x {};
        struct y {};
        using by_default = x;
    } // namespace method
} // namespace oneapi::dal::%ALGORITHM%

```

Computational Tasks

The supported computational tasks are declared within the `%ALGORITHM%::task` namespace using tag-types. Algorithm shall support at least one task and declare the `by_default` type alias that refers to one of the tasks as shown in the example below.

If an algorithm assumes both `classification` and `regression` tasks, the default task shall be `classification`. In some cases where an algorithm does not have the well-defined training and inference stages an algorithm may define only one task.

```

namespace oneapi::dal::%ALGORITHM% {
    namespace task {
        struct classification {};
        struct regression {};
        using by_default = classification;
    } // namespace task
} // namespace oneapi::dal::%ALGORITHM%

```

8.4.3 Operations

An **operation** is a function that transforms *a descriptor* and other arguments represented via *an input* object to *a result* object. An operation is responsible for:

- Executing all of an algorithm’s computational routines represented by the descriptor.
- Passing SYCL* queue to computational routines.
- Verifying preconditions and postconditions before and after the execution of computational routines.

General operation definition

The following code sample shows the declaration of an abstract operation. To declare a particular operation, the %OPERATION% shall be substituted with the name of the operation.

```
namespace oneapi::dal {

template <typename Descriptor>
using %OPERATION%_input_t = /* implementation defined */;

template <typename Descriptor>
using %OPERATION%_result_t = /* implementation defined */;

template <typename Descriptor>
%OPERATION%_result_t<Descriptor> %OPERATION%(
    sycl::queue& queue,
    const Descriptor& desc,
    const %OPERATION%_input_t<Descriptor>& input);
} // namespace oneapi::dal
```

Each operation shall satisfy the following requirements:

- An operation shall accept three parameters in the following order:
 - The SYCL* queue object
 - The descriptor of the algorithm
 - The *input object*
- An operation shall return the *result object*.
- The %OPERATION%_input_t and %OPERATION%_result_t alias templates shall be used for inference of the input and return types.
- If a precondition is violated, an operation shall throw an exception derived from oneapi::dal::logic_error.
- If a postcondition is violated, an operation shall throw an exception derived from oneapi::dal::runtime_error.
- If the descriptor is incompatible with some operation, an error shall be reported at compile-time.
- The exact list of compatible operations and pre-/post- conditions shall be defined by *a particular algorithm specification*.

Operation shortcuts

In order to make the code on user side less verbose, oneDAL defines the following overloaded functions called *shortcuts* for each operation in addition to the general one described in section *General operation definition*.

- A shortcut for execution on *host* that performs the same operation as the general function on host, but does not require the queue to be passed explicitly.

```
template <typename Descriptor>
%OPERATION%_result_t<Descriptor> %OPERATION%(
    const Descriptor& desc,
    const %OPERATION%_input_t<Descriptor>& input);
```

- A shortcut that allows omitting explicit input creation.

```
template <typename Descriptor, typename... Args>
%OPERATION%_result_t<Descriptor> %OPERATION%(
    sycl::queue& queue,
    const Descriptor& desc,
    Args&&... args);
```

- A shortcut that allows omitting explicit queue and input creation. This is a combination of two previous shortcuts.

```
template <typename Descriptor, typename... Args>
%OPERATION%_result_t<Descriptor> %OPERATION%(
    const Descriptor& desc,
    Args&&... args);
```

Input

An input object aggregates all the data that the algorithm requires for performing a specific operation. The data is represented via *tables*, so, typically, an input is a collection of tables, but not limited to them and can aggregate objects of an arbitrary type.

In general, input class definition is similar to *descriptor*. An input defines properties that can be accessed by means of the corresponding *getter* and *setter* methods. Requirements to the input's properties are the same as *requirements for descriptor's properties*.

The following code sample shows the common structure of a inputs's definition. To define an input for particular algorithm and operation, the following strings shall be substituted:

- %ALGORITHM% is the name of an algorithm and its namespace.
- %OPERATION% is the name of operation.
- %PROPERTY_NAME% and %PROPERTY_TYPE% are the name and the type of one of the input's properties.

```
namespace oneapi::dal::%ALGORITHM% {

template <typename Task = task::by_default>
class OPERATION_input {
public:
    /* Constructor */
    %OPERATION%_input(const %PROPERTY_TYPE%& %PROPERTY_NAME%,
                    /* more properties */)
};
```

(continues on next page)

(continued from previous page)

```

    /* Getter & Setter for the property called `PROPERTY_NAME` */
    descriptor& set_PROPERTY_NAME(%PROPERTY_TYPE% value);
    %PROPERTY_TYPE% get_PROPERTY_NAME() const;

    /* more properties */
};

} // namespace oneapi::dal::ALGORITHM%

```

Note: An input is specific to algorithm and operation, so each %ALGORITHM%-%OPERATION% pair shall define its own set of the properties.

Result

A result object aggregates all output values computed by the algorithm. All assumptions about *an input* are applied to a result as well.

```

namespace oneapi::dal::ALGORITHM% {

template <typename Task = task::by_default>
class OPERATION_result {
public:
    /* Constructor */
    %OPERATION%_result(const %PROPERTY_TYPE%& %PROPERTY_NAME%,
                    /* more properties */)

    /* Getter & Setter for the property called `PROPERTY_NAME` */
    descriptor& set_PROPERTY_NAME(%PROPERTY_TYPE% value);
    %PROPERTY_TYPE% get_PROPERTY_NAME() const;

    /* more properties */
};

} // namespace oneapi::dal::ALGORITHM%

```

Supported operation

Refer to the *Supported operations* section for more information about particular operations.

Supported operations

This section describes all operations supported by oneDAL. For more information about general operation definition, refer to *Operations* section.

The table below specifies whether an algorithm's descriptor can be used together with each operation.

Algorithm	Operations		
	<i>Train</i>	<i>Infer</i>	<i>Compute</i>
<i>K-Means</i>	Yes	Yes	No
<i>K-Means Initialization</i>	No	No	Yes
<i>k-NN</i>	Yes	Yes	No
<i>PCA</i>	Yes	Yes	No

Train

The train operation performs *training* procedure of a machine learning algorithm. The result obtained after the training contains a *model* that can be passed to the infer operation.

```
namespace oneapi::dal {

template <typename Descriptor>
using train_input_t = /* implementation defined */;

template <typename Descriptor>
using train_result_t = /* implementation defined */;

template <typename Descriptor>
train_result_t<Descriptor> train(
    sycl::queue& queue,
    const Descriptor& desc,
    const train_input_t<Descriptor>& input);

} // namespace oneapi::dal
```

Infer

The infer operation performs *inference* procedure of a machine learning algorithm based on the model obtained as a result of training.

```
namespace oneapi::dal {

template <typename Descriptor>
using infer_input_t = /* implementation defined */;

template <typename Descriptor>
```

(continues on next page)

(continued from previous page)

```

using infer_result_t = /* implementation defined */;

template <typename Descriptor>
infer_result_t<Descriptor> infer(
    sycl::queue& queue,
    const Descriptor& desc,
    const infer_input_t<Descriptor>& input);

} // namespace oneapi::dal

```

Compute

The compute operation is used if an algorithm does not have the well-defined training and inference stages.

```

namespace oneapi::dal {

template <typename Descriptor>
using compute_input_t = /* implementation defined */;

template <typename Descriptor>
using compute_result_t = /* implementation defined */;

template <typename Descriptor>
compute_result_t<Descriptor> compute(
    sycl::queue& queue,
    const Descriptor& desc,
    const compute_input_t<Descriptor>& input);

} // namespace oneapi::dal

```

8.4.4 Computational modes

Batch

In the batch processing mode, the algorithm works with the entire data set to produce the final result. A more complex scenario occurs when the entire data set is not available at the moment or the data set does not fit into the device memory.

Online

In the online processing mode, the algorithm processes a data set in blocks streamed into the device's memory. Partial results are updated incrementally and finalized when the last data block is processed.

Distributed

In the distributed processing mode, the algorithm operates on a data set distributed across several devices (compute nodes). On each node, the algorithm produces partial results that are later merged into the final result on the main node.

8.5 Common Interface

8.5.1 Current Version of this oneDAL Specification

This is the oneDAL specification which is part of the oneAPI specification version 1.0.

8.5.2 Header files

oneDAL public identifiers are represented in the following header files:

Header file	Description
oneapi/dal. hpp	The main header file of oneDAL library.
oneapi/dal/ %FILE%.hpp	The common type definitions used in other oneDAL layers. For example, <code>data_type</code> or <code>range</code> .
oneapi/dal/ algo/%ALGO%. hpp	A header file for a particular algorithm. The folder for the algorithm itself is <code>oneapi/dal/ algo/%ALGO%/</code> . The string <code>%ALGO%</code> should be substituted with the name of the algorithm, for example, <code>kmeans</code> or <code>knn</code> .
oneapi/dal/ algo/misc/ %FUNC%.hpp	A header file for miscellaneous data types and functionality that is intended to be used by oneDAL algorithms and applications of the analytical pipeline. The string <code>%FUNC%</code> should be substituted with the name of the functionality, for example, <code>mt19937</code> or <code>cross_entropy_loss</code> .
oneapi/ dal/table/ %FILE%.hpp	A header file for the types related to the <i>table</i> concept. The string <code>%FILE%</code> should be substituted with the name of the functionality, for example, <code>common</code> for key concepts related to table types (e.g., <code>table</code> , <code>table_metadata</code> , <code>data_layout</code> classes). For entities that have the <code>_table</code> suffix in their names, the related header file shall not contain this suffix in its name, for example, <code>homogen</code> for <code>homogen_table</code> class.
oneapi/dal/ io/%FILE%. hpp	A header file for the types and entities of input-output functionality. The string <code>%FILE%</code> should be substituted with the name of the functionality, for example, <code>csv</code> for reading and writing csv files.
oneapi/dal/ util/%UTIL%. hpp`	A header file for auxiliary functionality, such as memory allocators or type traits, that is intended to be used for the design of classes and implementation of various methods. The string <code>%UTIL%</code> should be substituted with the name of the auxiliary functionality, for example, <code>usm_allocator</code> or <code>type_traits</code> .

8.5.3 Namespaces

oneDAL functionality is represented with a system of C++ namespaces described below:

Namespace	oneDAL content
<code>oneapi::dal</code>	The namespace of the library that contains externally visible data types, data management entities, processing and service functionality of oneDAL.
<code>oneapi::dal::%ALGORITHM%</code>	The namespace of the algorithm. All classes and structures related to that algorithm shall be defined within this particular namespace. To define a namespace for a specific algorithm, the string <code>%ALGORITHM%</code> should be substituted with its name, for example, <code>oneapi::dal::kmeans</code> or <code>oneapi::dal::knn</code> .
<code>oneapi::dal::%DATA_SOURCE%</code>	The namespace of the data source. All classes and structures related to that data source shall be defined within a particular namespace. To define a specific data source, the string <code>%DATA_SOURCE%</code> should be substituted with its name, for example, <code>oneapi::dal::csv</code> .
<code>oneapi::dal::misc</code>	The namespace that contains miscellaneous data types and functionality intended to be used by oneDAL algorithms and applications for algorithm customization and optimization on various stages of the analytical pipeline.
<code>%PARENT%::detail</code>	The namespace that contains implementation details of the data types and functionality for the parent namespace. The namespace can be on any level in the namespace hierarchy. To define a specific namespace, the string <code>%PARENT%</code> should be substituted with the namespace for which the details are provided, for example, <code>oneapi::dal::detail</code> or <code>oneapi::dal::kmeans::detail</code> . The application shall not use any data types nor call any functionality located in the detail namespaces.

8.5.4 Error handling

oneDAL error handling relies on the mechanism of C++ exceptions. If an error occurs, it shall be propagated at the point of a function call where it is caught using standard C++ error handling mechanism.

Exception classification

Exception classification in oneDAL is aligned with C++ Standard Library classification. oneDAL shall introduce abstract classes that define the base class in the hierarchy of exception classes. Non-abstract exception classes are derived from the respective C++ Standard Library exception classes. oneDAL shall throw exceptions represented with non-abstract classes.

In the hierarchy of oneDAL exceptions, `oneapi::dal::exception` is the base abstract class that all other exception classes are derived from.

```
class oneapi::dal::exception;
```

Exception	Description	Abstract
<code>oneapi::dal::exception</code>	The base class of oneDAL exception hierarchy.	Yes

All oneDAL exceptions shall be divided into three groups:

- logic errors
- runtime errors

- errors with allocation

```
class oneapi::dal::logic_error : public oneapi::dal::exception;
class oneapi::dal::runtime_error : public oneapi::dal::exception;
class oneapi::dal::bad_alloc : public oneapi::dal::exception, public std::bad_alloc;
```

Exception	Description	Abstract
oneapi::dal::logic_error	Reports violations of preconditions and invariants.	Yes
oneapi::dal::runtime_error	Reports violations of postconditions and other errors happened during the execution of oneDAL functionality.	Yes
oneapi::dal::bad_alloc	Reports failure to allocate storage.	Yes

All precondition and invariant errors represented by `oneapi::dal::logic_error` shall be divided into the following groups:

- invalid argument errors
- domain errors
- out of range errors
- errors with an unimplemented method or algorithm
- unsupported device

```
class oneapi::dal::invalid_argument : public oneapi::dal::logic_error, public
↳std::invalid_argument;
class oneapi::dal::domain_error : public oneapi::dal::logic_error, public std::domain
↳error;
class oneapi::dal::out_of_range : public oneapi::dal::logic_error, public std::out_of
↳range;
class oneapi::dal::unimplemented : public oneapi::dal::logic_error, public std::logic
↳error;
class oneapi::dal::unsupported_device : public oneapi::dal::logic_error, public
↳std::logic_error;
```

Exception	Description	Abstract
oneapi::dal::invalid_argument	Reports situations when the argument was not accepted.	No
oneapi::dal::domain_error	Reports situations when the argument is outside of the domain on which the operation is defined. Higher priority than <code>oneapi::dal::invalid_argument</code> .	No
oneapi::dal::out_of_range	Reports situations when the index is out of range. Higher priority than <code>oneapi::dal::invalid_argument</code> .	No
oneapi::dal::unimplemented	Reports errors that arise because an algorithm or a method is not implemented.	No
oneapi::dal::unsupported_device	Reports situations when a device is not supported.	No

Errors that occur during the execution of oneDAL functionality are represented with `oneapi::dal::runtime_error`. Two main groups of errors shall be distinguished:

- errors in the destination type range
- errors in the OS facilities interaction

All other errors are reported via `oneapi::dal::internal_error`.

```
class oneapi::dal::range_error : public oneapi::dal::runtime_error, public std::range_
↳error;
class oneapi::dal::system_error : public oneapi::dal::runtime_error, public std::system_
↳error;
class oneapi::dal::internal_error : public oneapi::dal::runtime_error, public
↳std::runtime_error;
```

Exception	Description	Ab- strat
<code>oneapi::dal::range_error</code>	Reports situations where a result of a computation cannot be represented by the destination type.	No
<code>oneapi::dal::system_error</code>	Reports errors occurred during interaction with OS facilities.	No
<code>oneapi::dal::internal_error</code>	Reports all runtime errors that could not be assigned to other inheritors.	No

All memory allocation errors are represented by `oneapi::dal::bad_alloc`. They shall be divided into two groups based on where they occur:

- Host memory allocation error
- Device memory allocation error

```
class oneapi::dal::host_bad_alloc : public oneapi::dal::bad_alloc;
class oneapi::dal::device_bad_alloc : public oneapi::dal::bad_alloc;
```

Exception	Description	Ab- strat
<code>oneapi::dal::host_bad_alloc</code>	Reports failure to allocate storage on the host.	No
<code>oneapi::dal::device_bad_alloc</code>	Reports failure to allocate storage on the device.	No

8.5.5 Common type definitions

This section describes common types used in oneDAL.

Programming interface

All types and functions in this section shall be declared in the `oneapi::dal` namespace and be available via inclusion of the `oneapi/dal/common.hpp` header file.

Scalar types

oneDAL relies on the use of integral types defined in `<cstdint>`. This file shall be included in `oneapi/dal/common.hpp` and all oneDAL types shall use these data types.

The interfaces of the library shall use `std::int64_t` data type to represent dimensionality (for example, the number of rows and columns in the table).

It is recommended to use standard C++ types for applications as well.

Enum classes

Which base type to use when defining `enum` or `enum class` representing a oneDAL concept is up to the implementer unless specification requires a specific base type.

Data type

The implementation of *data type* concept. It shall enumerate all the data types supported by oneDAL to perform computations. The `data_type` class shall contain all the base *scalar types* and can also extend them. Base scalar types include the types whose names follow the pattern `std::int_XX_t` or `std::uint_XX_t`, where XX is 8, 16, 32, or 64.

```
enum class data_type {
    int8,
    int16,
    int32,
    int64,
    uint8,
    uint16,
    uint32,
    uint64,
    float32,
    float64,
    bfloat16
};
```

enum class **data_type**

data_type::int8 8-bit signed integer value type.

data_type::int16 16-bit signed integer value type.

data_type::int32 32-bit signed integer value type.

data_type::int64 64-bit signed integer value type.

data_type::uint8 8-bit unsigned integer value type.

data_type::uint16 16-bit unsigned integer value type.

data_type::uint32 32-bit unsigned integer value type.

data_type::uint64 64-bit unsigned integer value type.

data_type::float32 32-bit floating-point value type.

data_type::float64 64-bit floating-point value type.

data_type::bfloat16 bi-float value type.

Range

A range [start_index, end_index) in an array or any other container that supports value indexing.

```
struct range {
public:
    range(std::int64_t start, std::int64_t end);

    std::int64_t get_element_count(std::int64_t max_end_index) const noexcept;

    std::int64_t start_idx;

    std::int64_t end_idx;
};
```

struct **range**

Constructors

range(std::int64_t start, std::int64_t end)

Constructs a range of elements from the given start and end indices.

Parameters

- **start** – The first index in the range. The value shall be greater than or equal to 0.
- **end** – The relative end index in the range. Indicates the next index after the last one in the range. If positive, shall be greater than *start*. If negative, indicates the offset of the last element from the end of the range. For example, *start* = 1 and *end* = -2 specify the range of elements [1, 2, 3] in the set [0, 1, 2, 3, 4].

Public Methods

std::int64_t **get_element_count**(std::int64_t max_end_index) const noexcept

The number of elements in the range. The *max_end_index* value specifies the last maximal index in the sequence.

8.6 Data management

This section includes concepts and objects that operate on data. For oneDAL, such set of operations, or **data management**, is distributed between different stages of the *data analytics pipeline*. From a perspective of data management, this pipeline contains three main steps of data acquisition, preparation, and computation (see *the picture below*):

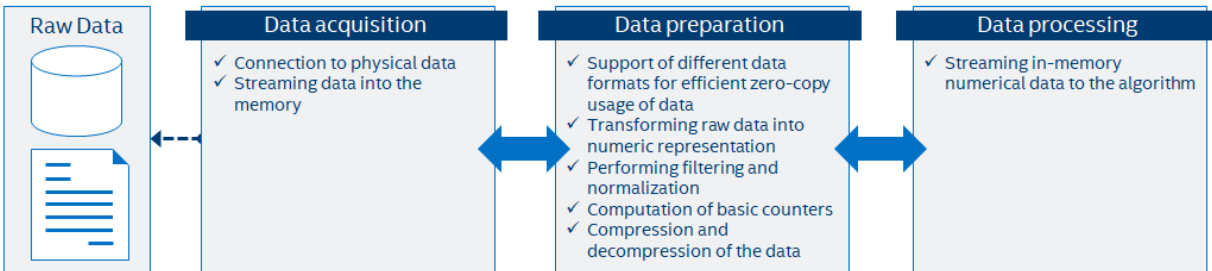

1. Raw data acquisition
 - Transfer out-of-memory data from various sources (databases, files, remote storage) into an in-memory representation.
2. Data preparation
 - Support different in-memory *data formats*.
 - Compress and decompress the data.
 - Convert the data into numeric representation.
 - Recover missing values.
 - Filter the data and perform data normalization.
 - Compute various statistical metrics for numerical data, such as mean, variance, and covariance.

3. Algorithm computation

- Stream in-memory numerical data to the algorithm.

In complex usage scenarios, data flow goes through these three stages back and forth. For example, when the data are not fully available at the start of the computation, it can be done step-by-step using blocks of data. After the computation on the current block is completed, the next block should be obtained and prepared.

Typical data management flow within oneDAL

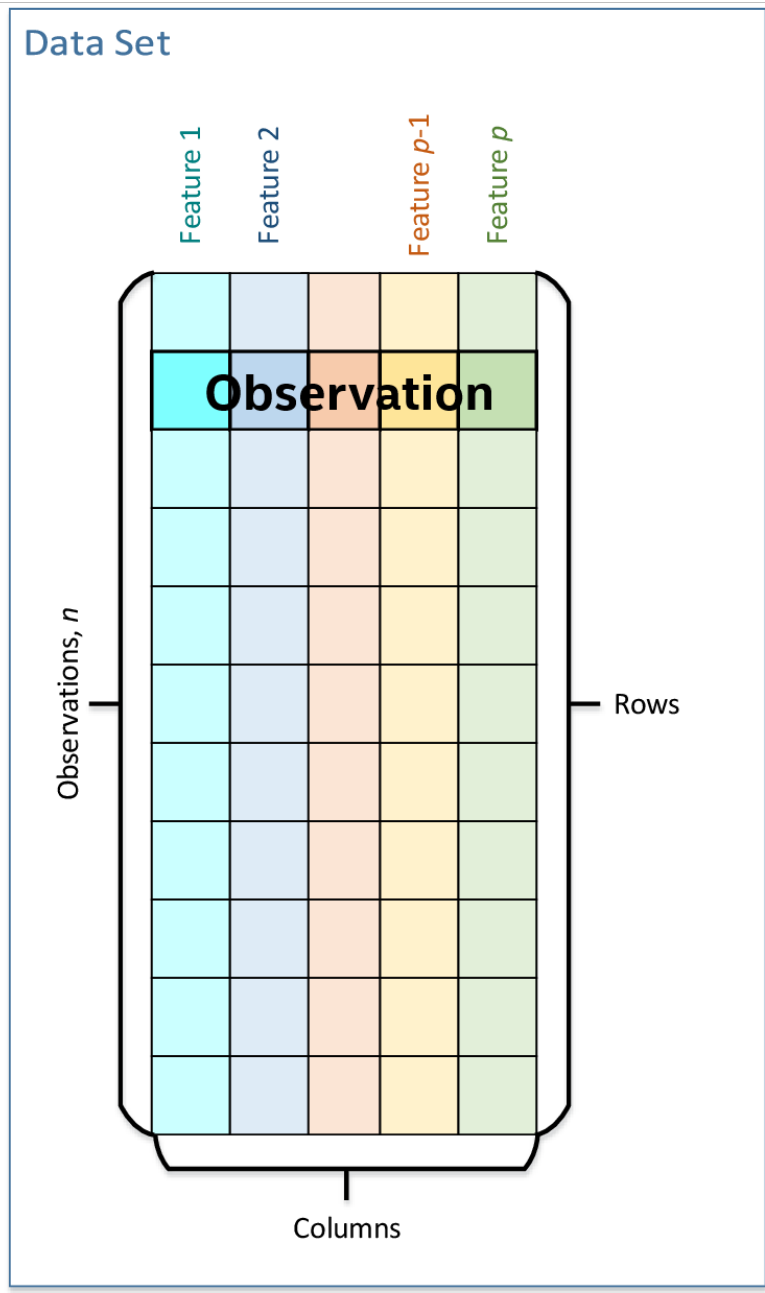

8.6.1 Key concepts

oneDAL provides a set of concepts to operate on out-of-memory and in-memory data during different stages of the *data analytics pipeline*.

Dataset

The main data-related concept that oneDAL works with is a *dataset*. It is a tabular view of data, where table rows represent the *observations* and columns represent the *features*.

The dataset is used across all stages of the data analytics pipeline. For example:

1. At the acquisition stage, it is downloaded into the local memory.
2. At the preparation stage, it is converted into a numerical representation.
3. At the computation stage, it is used as one of the *inputs* or *results* of an algorithm or a *descriptor* properties.

Data source

Data source is a concept of an out-of-memory storage for a *dataset*. It is used at the data acquisition and data preparation stages to:

- Extract datasets from external sources such as databases, files, remote storage.
- Load datasets into the device's local memory. Data do not always fit the local memory, especially when processing with accelerators. A data source provides the ability to load data by batches and extracts it directly into the device's local memory. Therefore, a data source enables complex data analytics scenarios, such as *online computations*.
- Transform datasets into their numerical representation. Data source shall automatically transform non-numeric *categorical* and *continuous* data values into one of the numeric *data formats*.

For details, see *data sources* section.

Table

Table is a concept of in-memory numerical data that are organized in a tabular view with several rows and columns. It is used at the data preparation and data processing stages to:

- Be an in-memory representation of a *dataset* or another tabular data (for example, matrices, vectors, and scalars).
- Store heterogeneous data in various *data formats*, such as dense, sparse, chunked, contiguous.
- Avoid unnecessary data copies during conversion from external data representations.
- Transfer memory ownership of the data from user application to the table, or share it between them.
- Connect with the *data source* to convert data from an out-of-memory into an in-memory representation.
- Support streaming of the data to the algorithm.
- Access the underlying data on a device in a required *data format*, e.g. by blocks with the defined *data layout*.

Note: For thread-safety reasons and better integration with external entities, a table provides a read-only access to the data within it, thus, table object shall be *immutable*.

This concept has different logical organization and physical *format of the data*:

- Logically, a table contains n rows and p columns. Every column may have its own type of data values and a set of allowed operations.
- Physically, a table can be organized in different ways: as a *homogeneous, contiguous* array of bytes, as a *heterogeneous* list of arrays of different *data types*, in a compressed-sparse-row format. The number of bytes needed to store the data differs from the number of elements $n \times p$ within a table.

For details, see *tables* section.

Table metadata

Table metadata concept provides an additional information about data in the table:

1. The *data types* of the columns.
2. The logical types of data in the columns: *nominal*, *ordinal*, *interval*, or *ratio*.

Only the properties of data that do not affect table concept definition shall be the part of metadata concept.

Warning: While extending the table concept, specification implementer shall distinguish whether a new property they are adding is a property of a particular `table` sub-type or a property of table metadata.

For example, *data layout* and *data format* are properties of table objects since they affect the structure of a table, its contract, and behavior. The list of names of features or columns inside the table is the example of metadata property.

Accessor

Accessor is a concept that defines a single way to extract the data from a *table*. It allows to:

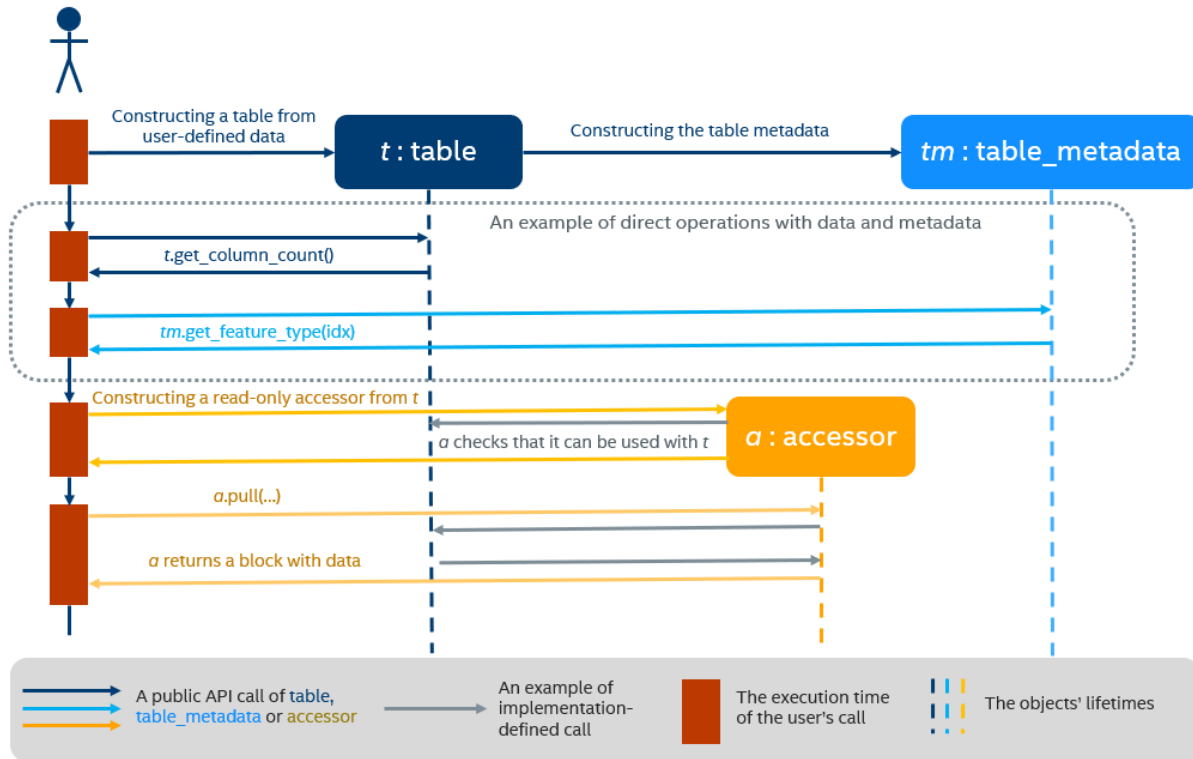

- Have unified access to the data from *table* objects of different types, without exposing their implementation details.
- Provide a *flat* view on the data blocks of a *table* for better data locality. For example, the accessor returns a column of the table stored in row-major format as a contiguous array.
- Acquire data in a desired *data format* for which a specific set of operations is defined.
- Have read-only access to the data.

For details, see *accessors* section.

Example of interaction between table and accessor objects

This section provides a basic usage scenario of the *table* and *accessor* concepts and demonstrates the relations between them. *The following diagram* shows objects of these concepts, which are highlighted by colors:

- *table* object is dark blue
- *accessor* is orange
- *table metadata* is light blue

To perform computations on a dataset, one shall create a `table` object first. It can be done either using a `data source` or directly from user-defined memory. The diagram shows the creation of a `table` object `t` from the data provided by user (not shown on the diagram). During a table creation, an object `tm` of table metadata is constructed and initialized using the data.

Once a table object is created, it can be used as an input in computations or as a parameter of some algorithm. The data in the table can be accessed via its own interface or via read-only accessor as shown on the diagram.

8.6.2 Details

This section includes the detailed descriptions of all data management objects in oneDAL.

Array

The array is a simple concept over the data in oneDAL. It represents a storage that:

1. Holds the data allocated inside it or references to the external data. The data are organized as one *homogeneous* and *contiguous* memory block.
2. Contains information about the memory block's size.
3. Represents either *immutable* or mutable data.
4. Provides an ability to change the data state from immutable to mutable one.
5. Holds ownership information on the data (see the *data ownership requirements* section).
6. Ownership information on the data can be shared between several arrays. It is possible to create a new array from another one without any data copies.

Usage example

The following listing provides a brief introduction to the array API and an example of basic usage scenario:

```
#include <CL/sycl.hpp>
#include <iostream>
#include <string>
#include "oneapi/dal/array.hpp"

using namespace oneapi;

void print_property(const std::string& description, const auto& property) {
    std::cout << description << ": " << property << std::endl;
}

int main() {
    sycl::queue queue { sycl::default_selector() };

    constexpr std::int64_t data_count = 4;
    const float data[] = { 1.0f, 2.0f, 3.0f, 4.0f };

    // Creating an array from immutable user-defined memory
    auto arr_data = dal::array<float>::wrap(data, data_count);

    // Creating an array from internally allocated memory filled by ones
    auto arr_ones = dal::array<float>::full(queue, data_count, 1.0f);

    print_property("Is arr_data mutable", arr_data.has_mutable_data()); // false
    print_property("Is arr_ones mutable", arr_ones.has_mutable_data()); // true

    // Creating new array from arr_data without data copy - they share ownership
    ↪information.
    dal::array<float> arr_mdata = arr_data;

    print_property("arr_mdata elements count", arr_mdata.get_count()); // equal to data_
    ↪count
    print_property("Is arr_mdata mutable", arr_mdata.has_mutable_data()); // false

    /// Copying data inside arr_mdata to new mutable memory block.
    /// arr_data still refers to the original data pointer.
    arr_mdata.need_mutable_data(queue);

    print_property("Is arr_data mutable", arr_data.has_mutable_data()); // false
    print_property("Is arr_mdata mutable", arr_mdata.has_mutable_data()); // true

    queue.submit([&](sycl::handler& cgh){
        auto mdata = arr_mdata.get_mutable_data();
        auto cones = arr_ones.get_data();
        cgh.parallel_for<class array_addition>(sycl::range<1>(data_count), [=](sycl::id<1>
    ↪idx) {
            mdata[idx[0]] += cones[idx[0]];
        });
    }).wait();
}
```

(continues on next page)

(continued from previous page)

```
std::cout << "arr_mdata values: ";
for(std::int64_t i = 0; i < arr_mdata.get_count(); i++) {
    std::cout << arr_mdata[i] << ", ";
}
std::cout << std::endl;

return 0;
}
```

Data ownership requirements

The array shall satisfy the following requirements on managing the memory blocks:

1. An array shall retain:
 - A pointer to the immutable data block of size `count`;
 - A pointer to the mutable data block of size `count`.
2. If an array represents mutable data, both pointers shall point to the mutable data block.
3. If an array represents immutable data, pointer to the mutable data block shall be `nullptr`.
4. An array shall use shared ownership semantics to manage the lifetime of the stored data block:
 - Several array objects may own the same data block;
 - An array releases the ownership when one of the following happens:
 - The array owning the data block is destroyed;
 - The array owning the data block is assigned another memory block via `operator=` or `reset()`;
 - If the array that releases the ownership is the last remaining object owning the data block, the release of ownership is followed by the data block deallocation.
 - The data block is deallocated using the deleter object that is provided to array during construction. If no deleter object provided, an array calls the default deallocating function that corresponds to the internal memory allocation mechanism.
5. If a managed pointer to the data block is replaced by another pointer via `reset()`, the array that managed the pointer releases the ownership of it and starts managing the lifetime of the data block represented by the other pointer.
6. If an array changes its state from immutable to mutable via `need_mutable_data()`, it releases the ownership of immutable data block and start managing lifetime of the mutable data block.
7. An array object may own no data. An array like this is called **zero-sized**:
 - Pointers to the immutable and mutable data of the zero-sized array shall be `nullptr`;
 - The data block size `count` shall be `0`.

Implementation notes

A typical array implementation may be organized in the following way:

1. An array class has the following member variables:
 - A pointer to the immutable data block;
 - A pointer to the mutable data block;
 - A pointer to the ownership structure that implements the shared ownership semantics;
 - The data block size count;
2. An ownership structure is an object that stores:
 - A pointer to either immutable or mutable data block;
 - The deleter object;
 - The reference count (the number of array objects that own the associated data block);
3. If an array starts managing the lifetime of the data block represented by the pointer `p` and deleter `d`, it creates the ownership structure object and initialize it with `p` and `d`. The reference count of the ownership structure is assigned one.
4. If an array object releases the ownership, the reference count of the ownership structure is decremented.
 - If that count reaches zero, the ownership structure deallocates the memory block and the array destroys the ownership structure.
 - If that count is greater than zero, the ownership structure is not destroyed.
5. If a copy of the array object is created, the reference count of the ownership structure is incremented and a pointer to the same ownership structure is assigned to the created copy. The other member variables of an array class are copied as is.

Note: You may choose an arbitrary implementation strategy that satisfies array requirements.

Programming interface

All types and functions in this section shall be declared in the `oneapi::dal` namespace and be available via inclusion of the `oneapi/dal/array.hpp` header file.

All the array class methods can be divided into several groups:

1. Constructors that are used to create an array from external, mutable or immutable memory.
2. Constructors and assignment operators that are used to create an array that shares its data with another one.
3. The group of `reset()` methods that are used to re-assign an array to another external memory block.
4. The group of `reset()` methods that are used to re-assign an array to an internally allocated memory block.
5. The methods that are used to access the data.
6. Static methods that provide simplified ways to create an array either from external memory or by allocating it within a new object.

```

template <typename Data>
class array {
public:
    using data_t = Data;

    static array<Data> empty(const sycl::queue& queue,
                           std::int64_t count,
                           const sycl::usm::alloc& alloc = sycl::usm::alloc::shared);

    template <typename Element>
    static array<Data> full(sycl::queue& queue,
                          std::int64_t count,
                          Element&& element,
                          const sycl::usm::alloc& alloc = sycl::usm::alloc::shared);

    static array<Data> zeros(sycl::queue& queue,
                            std::int64_t count,

    array& need_mutable_data(sycl::queue& queue,
                          const sycl::usm::alloc& alloc = sycl::usm::alloc::shared);

```

(continues on next page)

(continued from previous page)

```

std::int64_t get_count() const noexcept;

std::int64_t get_size() const noexcept;

const Data& operator[](std::int64_t index) const noexcept;

void reset();

void reset(const sycl::queue& queue,
           std::int64_t count,
           const sycl::usm::alloc& alloc = sycl::usm::alloc::shared);

template <typename ExtData, typename Deleter>
void reset(ExtData* data,
           std::int64_t count,
           Deleter&& deleter,
           const std::vector<sycl::event>& dependencies = {});

template <typename RefData, typename ExtData>
void reset(const array<RefData>& ref, ExtData* data, std::int64_t count);
};

```

```

template<typename Data>
class array

```

Template Parameters **Data** – The type of the memory block elements within the array. *Data* can represent any *data type*.

Public Static Methods

```

static array<Data> empty(const sycl::queue &queue, std::int64_t count, const sycl::usm::alloc &alloc =
                        sycl::usm::alloc::shared)

```

Creates a new array instance by allocating a mutable memory block. The created array manages the lifetime of the allocated memory block. The function is not required to initialize the values of the allocated memory block.

Parameters

- **queue** – The SYCL* queue object.
- **count** – The number of elements of type *Data* to allocate memory for.
- **alloc** – The kind of USM to be allocated.

Preconditions

```

count > 0

```

Postconditions

```

get_count() == count
has_mutable_data() == true

```

```

template<typename Element>
static array<Data> full(sycl::queue &queue, std::int64_t count, Element &&element, const sycl::usm::alloc
                        &alloc = sycl::usm::alloc::shared)

```

Creates a new array instance by allocating a mutable memory block and filling its content with a scalar

value. The created array manages the lifetime of the allocated memory block.

Template Parameters **Element** – The type from which array elements of type *Data* can be constructed.

Parameters

- **queue** – The SYCL* queue object.
- **count** – The number of elements of type *Data* to allocate memory for.
- **element** – The value that is used to fill a memory block.
- **alloc** – The kind of USM to be allocated.

Preconditions

```
count > 0
```

Postconditions

```
get_count() == count
has_mutable_data() == true
get_data()[i] == element, 0 <= i < count
```

```
static array<Data> zeros(sycl::queue &queue, std::int64_t count, const sycl::usm::alloc &alloc =
    sycl::usm::alloc::shared)
```

Creates a new array instance by allocating a mutable memory block and filling its content with zeros. The created array manages the lifetime of the allocated memory block.

Parameters

- **queue** – The SYCL* queue object.
- **count** – The number of elements of type *Data* to allocate memory for.
- **alloc** – The kind of USM to be allocated.

Preconditions

```
count > 0
```

Postconditions

```
get_count() == count
has_mutable_data() == true
get_data()[i] == 0, 0 <= i < count
```

```
template<typename ExtData>
static array<Data> wrap(ExtData *data, std::int64_t count, const std::vector<sycl::event> &dependencies =
    {})
```

Creates a new array instance from a pointer to externally-allocated memory block. The created array does not manage the lifetime of the user-provided memory block. It is the responsibility of the programmer to make sure that *data* pointer remains valid as long as this array object exists.

Template Parameters **ExtData** – Either *Data* or *const Data* type.

Parameters

- **data** – The pointer to the mutable or immutable externally-allocated memory block.
- **count** – The number of elements of type *Data* in the memory block.
- **dependencies** – Events indicating the availability of the *data* for reading or writing.

Preconditions

```
data != nullptr
count > 0
```

Postconditions

```
get_count() == count
get_data() == data
has_mutable_data() == false
```

Constructors**array()**

Creates a zero-sized array without memory allocation.

Postconditions

```
get_count() == 0
get_data() == nullptr
has_mutable_data() == false
```

array(const array<Data> &other)

Creates a new array instance that shares an ownership with the *other* array.

array(array<Data> &&other)

Creates a new array instance that transfers the ownership from the *other* array. After the construction of a new instance, the behaviour of the *other* is defined by the implementation.

Postconditions

```
other.get_count() == 0
other.get_data() == nullptr
has_mutable_data() == false
```

template<typename **ExtData**, typename **Deleter**>

array(const sycl::queue &queue, *ExtData* *data, std::int64_t count, *Deleter* &&deleter, const std::vector<sycl::event> &dependencies = {})

Creates a new array instance from a pointer to externally-allocated memory block. The created array manages the lifetime of the user-provided memory block. The memory block is deallocated using a custom deleter object provided by the user.

Template Parameters

- **ExtData** – Either *Data* or *const Data* type.
- **Deleter** – The type of a deleter used to deallocate the *data*. The expression `deleter(data)` must be well-formed (can be compiled) and not throw any exceptions.

Parameters

- **queue** – The SYCL* queue object.
- **data** – The pointer to the mutable or immutable externally-allocated mutable data.
- **count** – The number of elements of type *Data* in the memory block.
- **deleter** – The object used to deallocate *data*.
- **dependencies** – Events that indicate when *data* becomes ready to be read or written.

Preconditions

```
data != nullptr
count > 0
```

Postconditions

```
get_count() == count
get_data() == data
has_mutable_data() == true
get_mutable_data() == data
```

```
template<typename RefData, typename ExtData>
array(const array<RefData> &ref, ExtData *data, std::int64_t count)
```

Creates a new array instance that shares the ownership with the reference array while storing the pointer to another memory block provided by the user. The lifetime of the user-provided memory block is not managed by the created array. One of the use cases of this constructor is the creation of an array with an offset, for example, `array{ other, other.get_data() + offset }`. The array created this way shares the ownership with the *other*, but points to its data with an offset. It is the responsibility of the programmer to make sure that *data* pointer remains valid as long as this array object exists.

Template Parameters

- **RefData** – The type of elements in the reference array.
- **ExtData** – Either *Data* or *const Data* type.

Parameters

- **ref** – The reference array which shares the ownership with the created one.
- **data** – The unmanaged pointer to the mutable or immutable externally-allocated memory block.
- **count** – The number of elements of type *Data* in the *data*.

Preconditions

```
data != nullptr
count > 0
```

Postconditions

```
get_count() == count
get_data() == data
```

Public Methods

```
array<Data> operator=(const array<Data> &other)
```

Replaces the immutable and mutable data pointers and the number of elements by the values stored in the *other* array.

Postconditions

```
get_data() == other.get_data()
get_count() == other.get_count()
get_mutable_data() == other.get_mutable_data()
```

```
array<Data> operator=(array<Data> &&other)
```

Replaces the immutable and mutable data pointers and the number of elements by the values stored in the *other* array.

Postconditions

```

    get_data() == other.get_data()
    get_count() == other.get_count()
    get_mutable_data() == other.get_mutable_data()

```

const Data ***get_data**() const noexcept
The pointer to the immutable memory block.

bool **has_mutable_data**() const noexcept
Returns whether an array contains mutable data or not.

Data ***get_mutable_data**() const
The pointer to the mutable memory block.

Preconditions

```
has_mutable_data() == true, otherwise throws domain_error
```

array &**need_mutable_data**(sycl::queue &queue, const sycl::usm::alloc &alloc = sycl::usm::alloc::shared)
Does nothing if an array contains mutable data. Otherwise, allocates a mutable memory block and copies the content of the immutable memory block into it. The array manages the lifetime of the allocated mutable memory block. Returns the reference to the same array instance.

Parameters

- **queue** – The SYCL* queue object.
- **alloc** – The kind of USM to be allocated.

Postconditions

```
has_mutable_data() == true
```

std::int64_t **get_count**() const noexcept
The number of elements of type *Data* in a memory block.

std::int64_t **get_size**() const noexcept
The size of memory block in bytes.

const Data &**operator**[(std::int64_t index)] const noexcept
Provides a read-only access to the elements of an array. No bounds checking is performed.

void **reset**()
Releases the ownership of the managed memory block.

Preconditions

```
count > 0
```

Postconditions

```

get_count() == count
has_mutable_data() == true

```

void **reset**(const sycl::queue &queue, std::int64_t count, const sycl::usm::alloc &alloc = sycl::usm::alloc::shared)

Releases the ownership of the managed memory block and replaces it by a newly allocated mutable memory block. The lifetime of the allocated memory block is managed by the array.

Parameters

- **queue** – The SYCL* queue object.
- **count** – The number of elements of type *Data* to allocate memory for.

- **alloc** – The kind of USM to be allocated.

Preconditions

```
count > 0
```

Postconditions

```
get_count() == count
```

```
template<typename ExtData, typename Deleter>
void reset(ExtData *data, std::int64_t count, Deleter &&deleter, const std::vector<sycl::event>
    &dependencies = {})
```

Releases the ownership of the managed memory block and replace it by a pointer to externally-allocated memory block. The lifetime of the memory block is managed by the array. The memory block is deallocated using a custom deleter object provided by the user.

Template Parameters

- **ExtData** – Either *Data* or *const Data* type.
- **Deleter** – The type of a deleter used to deallocate the *data*. The expression `deleter(data)` must be well-formed (can be compiled) and not throw any exceptions.

Parameters

- **data** – The pointer to the to the mutable or immutable externally-allocated memory block.
- **count** – The number of elements of type *Data* in the *data*.
- **deleter** – The object used to deallocate *data*.
- **dependencies** – Events indicating the availability of the *data* for reading or writing.

Preconditions

```
data != nullptr
count > 0
```

Postconditions

```
get_count() == count
get_data() == data
has_mutable_data() == true
get_mutable_data() == data
```

```
template<typename RefData, typename ExtData>
void reset(const array<RefData> &ref, ExtData *data, std::int64_t count)
```

Releases the ownership of the managed memory block and starts managing the lifetime of the reference array while storing the pointer to another memory block provided by the user. The lifetime of the user-provided memory block is not managed. It is the responsibility of the programmer to make sure that *data* pointer remains valid as long as this array object exists.

Template Parameters

- **RefData** – The type of elements in the reference array.
- **ExtData** – Either *Data* or *const Data* type.

Parameters

- **ref** – The reference array which shares the ownership with the created one.

- **data** – The unmanaged pointer to the mutable or immutable externally-allocated memory block.
- **count** – The number of elements of type *Data* in the *data*.

Preconditions

```
data != nullptr
count > 0
```

Postconditions

```
get_count() == count
get_data() == data
```

Accessors

This section defines *requirements* to an *accessor* implementation and introduces several *accessor types*.

Requirements

Each accessor implementation shall:

1. Define a single *format of the data* for the access. Every accessor type shall return and use only one data format.
2. Provide read-only access to the data in the *table* types.
3. Provide the `pull()` method for obtaining the values from the table.
4. Be lightweight. Its constructors shall not have computationally intensive operations such data copy, reading, or conversion. These operations shall be performed by method `pull()`. Support of copy- and move- constructors by the accessor is not required since it shall be designed for use in a local scope - directly in a place when it is created.
5. The `pull()` method shall avoid data copy and conversion when it is possible to return the pointer to the memory block in the table. This is applicable for cases such as when the *data format* and *data types* of the data within the table are the same as the *data format* and *data type* for the access.

Accessor Types

oneDAL defines a set of accessor classes. Each class supports one specific way of obtaining data from the *table*.

All accessor classes in oneDAL are listed below:

Accessor type	Description	List of supported types
<i>row accessor</i>	Provides access to the range of rows as one <i>contiguous homogeneous</i> block of memory.	<i>homogen table</i>
<i>column accessor</i>	Provides access to the range of values within a single column as one <i>contiguous homogeneous</i> block of memory.	<i>homogen table</i>

Details

Column accessor

The `column_accessor` class provides a read-only access to the column values of the *table* as *contiguous homogeneous* array.

Usage example

```
#include <CL/sycl.hpp>
#include <iostream>

#include "oneapi/dal/table/homogen.hpp"
#include "oneapi/dal/table/column_accessor.hpp"

using namespace oneapi;

int main() {
    sycl::queue queue { sycl::default_selector() };

    constexpr float host_data[] = {
        1.0f, 1.5f, 2.0f,
        2.1f, 3.2f, 3.7f,
        4.0f, 4.9f, 5.0f,
        5.2f, 6.1f, 6.2f
    };

    constexpr std::int64_t row_count = 4;
    constexpr std::int64_t column_count = 3;

    auto shared_data = sycl::malloc_shared<float>(row_count * column_count, queue);
    auto event = queue.memcpy(shared_data, host_data, sizeof(float) * row_count * column_
→count);
    auto t = dal::homogen_table::wrap(queue, data, row_count, column_count, { event });

    // Accessing whole elements in a first column
    dal::column_accessor<const float> acc { t };

    auto block = acc.pull(queue, 0);
    for(std::int64_t i = 0; i < block.get_count(); i++) {
        std::cout << block[i] << ", ";
    }
    std::cout << std::endl;

    sycl::free(shared_data, queue);
    return 0;
}
```

Programming interface

All types and functions in this section shall be declared in the `oneapi::dal` namespace and be available via inclusion of the `oneapi/dal/table/column_accessor.hpp` header file.

```
template <typename Data>
class column_accessor {
public:
    using data_t = std::remove_const_t<Data>;

public:
    column_accessor(const table& obj);

    array<data_t> pull(sycl::queue& queue,
                     std::int64_t column_index,
                     const range& rows           = { 0, -1 },
                     const sycl::usm::alloc& alloc = sycl::usm::alloc::shared) const;

    Data* pull(sycl::queue& queue,
              array<data_t>& block,
              std::int64_t column_index,
              const range& rows           = { 0, -1 },
              const sycl::usm::alloc& alloc = sycl::usm::alloc::shared) const;
};
```

```
template<typename Data>
class column_accessor
```

Template Parameters `Data` – The type of data values in blocks returned by the accessor. Shall be const-qualified for read-only access. An accessor shall support at least `float`, `double`, and `std::int32_t` types of `Data`.

Constructors

`column_accessor`(const *table* &obj)

Creates a new read-only accessor object from the table. The check that the accessor supports the table kind of *obj* shall be performed. The reference to the *obj* table shall be stored within the accessor to obtain data from the table.

Public Methods

`array<data_t>` `pull`(sycl::queue &queue, std::int64_t column_index, const *range* &rows = {0, -1}, const sycl::usm::alloc &alloc = sycl::usm::alloc::shared) const

Provides access to the column values of the table. The method shall return an array that directly points to the memory within the table if it is possible. In that case, the array shall refer to the memory as to immutable data. Otherwise, the new memory block shall be allocated, the data from the table rows shall be converted and copied into this block. The array shall refer to the block as to mutable data.

Parameters

- **queue** – The SYCL* queue object.
- **column_index** – The index of the column from which the data shall be returned by the accessor.
- **rows** – The range of rows that should be read in the *column_index* block.
- **alloc** – The requested kind of USM in the returned block.

Preconditions

rows are within the range of $[0, obj.row_count)$.

column_index is within the range of $[0, obj.column_count)$.

Data `*pull`(sycl::queue &queue, *array*<data_t> &block, std::int64_t column_index, const *range* &rows = {0, -1}, const sycl::usm::alloc &alloc = sycl::usm::alloc::shared) const

Provides access to the column values of the table. The method shall return the *block*.data pointer.

Parameters

- **queue** – The SYCL* queue object.
- **block** – The block which memory is reused (if it is possible) to obtain the data from the table. The block memory shall be reset either when its size is not big enough, or when it contains immutable data, or when direct memory from the table can be used. If the block is reset to use a direct memory pointer from the object, it shall refer to this pointer as to immutable memory block.
- **column_index** – The index of the column from which the data shall be returned by the accessor.
- **rows** – The range of rows that should be read in the *column_index* block.
- **alloc** – The requested kind of USM in the returned block.

Preconditions

rows are within the range of $[0, obj.row_count)$.

column_index is within the range of $[0, obj.column_count)$.

Row accessor

The `row_accessor` class provides a read-only access to the rows of the *table* as *contiguous homogeneous* array.

Usage example

```
#include <CL/sycl.hpp>
#include <iostream>

#include "oneapi/dal/table/homogen.hpp"
#include "oneapi/dal/table/row_accessor.hpp"

using namespace oneapi;

int main() {
    sycl::queue queue { sycl::default_selector() };

    constexpr float host_data[] = {
        1.0f, 1.5f, 2.0f,
        2.1f, 3.2f, 3.7f,
        4.0f, 4.9f, 5.0f,
        5.2f, 6.1f, 6.2f
    };
};
```

(continues on next page)

(continued from previous page)

```

constexpr std::int64_t row_count = 4;
constexpr std::int64_t column_count = 3;

auto shared_data = sycl::malloc_shared<float>(row_count * column_count, queue);
auto event = queue.memcpy(shared_data, host_data, sizeof(float) * row_count * column_
↪count);
auto t = dal::homogen_table::wrap(queue, data, row_count, column_count, { event });

// Accessing second and third rows of the table
dal::row_accessor<const float> acc { t };

auto block = acc.pull(queue, {1, 3});
for(std::int64_t i = 0; i < block.get_count(); i++) {
    std::cout << block[i] << ", ";
}
std::cout << std::endl;

sycl::free(shared_data, queue);
return 0;
}

```

Programming interface

All types and functions in this section shall be declared in the `oneapi::dal` namespace and be available via inclusion of the `oneapi/dal/table/row_accessor.hpp` header file.

```

template <typename Data>
class row_accessor {
public:
    using data_t = std::remove_const_t<Data>;

public:
    row_accessor(const table& obj);

    array<data_t> pull(sycl::queue& queue,
                    const range& rows = { 0, -1 },
                    const sycl::usm::alloc& alloc = sycl::usm::alloc::shared) const;

    Data* pull(sycl::queue& queue,
              array<data_t>& block,
              const range& rows = { 0, -1 },
              const sycl::usm::alloc& alloc = sycl::usm::alloc::shared) const;
};

```

```

template<typename Data>
class row_accessor

```

Template Parameters `Data` – The type of data values in blocks returned by the accessor. Shall be const-qualified for read-only access. An accessor shall support at least `float`, `double`, and `std::int32_t` types of `Data`.

Constructors

row_accessor(const *table* &obj)

Creates a new read-only accessor object from the table. The check that the accessor supports the table kind of *obj* shall be performed. The reference to the *obj* table shall be stored within the accessor to obtain data from the table.

Public Methods

array<data_t> **pull**(sycl::queue &queue, const *range* &rows = {0, -1}, const sycl::usm::alloc &alloc = sycl::usm::alloc::shared) const

Provides access to the rows of the table. The method shall return an array that directly points to the memory within the table if it is possible. In that case, the array shall refer to the memory as to immutable data. Otherwise, the new memory block shall be allocated, the data from the table rows shall be converted and copied into this block. The array shall refer to the block as to mutable data.

Parameters

- **queue** – The SYCL* queue object.
- **rows** – The range of rows that data shall be returned from the accessor.
- **alloc** – The requested kind of USM in the returned block.

Preconditions

rows are within the range of $[0, obj.row_count)$.

Data ***pull**(sycl::queue &queue, *array*<data_t> &block, const *range* &rows = {0, -1}, const sycl::usm::alloc &alloc = sycl::usm::alloc::shared) const

Provides access to the rows of the table. The method shall return the *block.data* pointer.

Parameters

- **queue** – The SYCL* queue object.
- **block** – The block which memory is reused (if it is possible) to obtain the data from the table. The block memory shall be reset either when its size is not big enough, or when it contains immutable data, or when direct memory from the table can be used. If the block is reset to use a direct memory pointer from the object, it shall refer to this pointer as to immutable memory block.
- **rows** – The range of rows that data shall be returned from the accessor.
- **alloc** – The requested kind of USM in the returned block.

Preconditions

rows are within the range of $[0, obj.row_count)$.

Data Sources

This section describes the types related to the *data source* concept.

Read

Read operation is a function that transforms a data source and other arguments represented via *an args* object to a *result* object. The operation is responsible for:

- Executing all of the data retrieval and transformation routines of the data source.
- Passing a SYCL* queue to the data retrieval and transformation routines.

Read operation definition

The following code sample shows the declaration for a read operation.

```
namespace oneapi::dal {

template <typename Object, typename DataSource>
using read_args_t = /* implementation defined */;

template <typename Object, typename DataSource>
using read_result_t = Object;

template <typename Object, typename DataSource>
read_result_t<Object, DataSource> read(
    sycl::queue& queue,
    const DataSource& data_source,
    const read_args_t<Object, DataSource>& args);

} // namespace oneapi::dal
```

Each operation shall satisfy the following requirements:

- An operation shall accept three parameters in the following order:
 - The SYCL* queue object.
 - The data source.
 - The *args object*.
- An operation shall return the *result object*.
- The `read_args_t` and `read_result_t` alias templates shall be used for inference of the args and return types.

Read operation shortcuts

In order to make the code on user side less verbose, oneDAL defines the following overloaded functions called *shortcuts* for a read operation in addition to the general one described in section *Read operation definition*.

- A shortcut for execution on *host*. Performs the same operation as the general function on host, but does not require passing the queue explicitly.

```
template <typename Object, typename DataSource>
read_result_t<Object, DataSource> read(
    const DataSource& data_source,
    const read_args_t<Object, DataSource>& args);
```

- A shortcut that allows omitting explicit args creation.

```

template <typename Object, typename DataSource, typename... Args>
read_result_t<Object, DataSource> read(
    sycl::queue& queue,
    const DataSource& data_source,
    Args&&... args);

```

- A shortcut that allows omitting explicit queue and args creation. This is a combination of two previous shortcuts.

```

template <typename Object, typename DataSource, typename... Args>
read_result_t<Object, DataSource> read(
    const DataSource& data_source,
    Args&&... args);

```

Args

- The string `%DATA_SOURCE%` should be substituted with the name of the data source, for example, `csv`.
- `%PROPERTY_NAME%` and `%PROPERTY_TYPE%` should be substituted with the name and the type of one of the data source args properties.

```

namespace oneapi::dal::%DATA_SOURCE% {

template <typename Object, typename DataSource>
class read_args {
public:
    read_args(
        const %PROPERTY_TYPE_1%& property_name_1,
        const %PROPERTY_TYPE_2%& property_name_2,
        /* more properties */
    )
    /* Getter & Setter for the property called `PROPERTY_NAME_1` */
    descriptor& set_%PROPERTY_NAME_1%(%PROPERTY_TYPE_1% value);
    %PROPERTY_TYPE_1% get_%PROPERTY_NAME_1%() const;
    /* Getter & Setter for the property called `PROPERTY_NAME_2` */
    descriptor& set_%PROPERTY_NAME_2%(%PROPERTY_TYPE_2% value);
    %PROPERTY_TYPE_2% get_%PROPERTY_NAME_2%() const;
    /* more properties */
};
} // namespace oneapi::dal::%DATA_SOURCE%

```

Result

The result of a read operation is an instance of an in-memory object with `Object` type.

Data Source Types

oneDAL defines a set of classes.

Data source type	Description
<i>CSV data source</i>	Data source that allows reading data from a text file into a <i>table</i> .

Details

CSV data source

Class `csv::data_source` is an API for accessing the data source represented as a *csv file*. CSV data source shall be used with read operation to extract data in text format from the given input file, process it using provided parameters (such as delimiter and read options), transform it into numerical representation, and store it as an in-memory *dataset* of a chosen type.

Supported type of in-memory object for read operation with CSV data source is `oneapi::dal::table`.

CSV data source requires input file name to be set in the constructor, while the other parameters of the constructor such as delimiter and read options rely on default values.

Usage example

```
using namespace oneapi;

const auto data_source = dal::csv::data_source("data.csv", ',');

const auto table = dal::read<dal::table>(data_source);
```

Programming Interface

All types and functions in this section shall be declared in the `oneapi::dal::csv` namespace and be available via inclusion of the `oneapi/dal/io/csv.hpp` header file.

```
enum class read_options : std::uint64_t {
    none = 0,
    parse_header = 1 << 0
};

constexpr char default_delimiter = ',';
constexpr read_options default_read_options = read_options::none;
```

(continues on next page)

(continued from previous page)

```

class data_source {
public:
    data_source(const char *file_name,
                char delimiter = default_delimiter,
                read_options opts = default_read_options);

    data_source(const std::string &file_name,
                char delimiter = default_delimiter,
                read_options opts = default_read_options);

    std::string get_file_name() const;
    char get_delimiter() const;
    read_options get_read_options() const;
};

```

class **data_source**

data_source(const char *file_name, char delimiter = default_delimiter, read_options opts = default_read_options)

Creates a new instance of a CSV data source with the given *file_name*, *delimiter* and read options *opts* flag.

data_source(const std::string &file_name, char delimiter = default_delimiter, read_options opts = default_read_options)

Creates a new instance of a CSV data source with the given *file_name*, *delimiter* and read options *opts* flag.

std::string **file_name** = ""

A string that contains the name of the file with the dataset to read.

Getter

std::string get_filename() const

char **delimiter** = default_delimiter

A character that represents the delimiter between separate features in the input file.

Getter

char get_delimiter() const

read_options **options** = default_read_options

Value that stores read options to be applied during reading of the input file. Enabled `parse_header` option indicates that the first line in the input file shall be processed as a header record with features names.

Getter

read_options get_read_options() const

Reading `oneapi::dal::read<Object>(...)`

Args

```
template <typename Object>
class read_args {
public:
    read_args();
};
```

```
template<typename Object>
class read_args
```

`read_args()`

Creates args for the read operation with the default attribute values.

Operation

`oneapi::dal::table` is the only supported value of the `Object` template parameter for `read` operation with CSV data source.

```
template<typename Object, typename DataSource>
Object read(const DataSource &ds)
```

Template Parameters

- **Object** – oneDAL object type that shall be produced as a result of reading from the data source.
- **DataSource** – CSV data source `csv::data_source`.

Tables

This section describes the types related to the `table` concept.

Type	Description
<code>table</code>	A common implementation of the table concept. Base class for other table types.
<code>table_metadata</code>	An implementation of <code>table metadata</code> concept.
<code>data_layout</code>	An enumeration of <code>data layouts</code> used to store contiguous data blocks inside the table.
<code>feature_type</code>	An enumeration of <code>feature</code> types used in oneDAL to define set of available operations onto the data.

Requirements on table types

Each implementation of *table* concept shall:

1. Follow the definition of the *table* concept and its restrictions (e.g., *immutability*).
2. Be derived from the `oneapi::dal::table` class. The behavior of this class can be extended, but cannot be weakened.
3. Be *reference-counted*.
4. Every new `oneapi::dal::table` sub-type shall define a unique id number - the “kind” that represents objects of that type in runtime.

The following listing provides an example of table API to illustrate table kinds and copy-assignment operation:

```
using namespace onedal;

// Creating homogen_table sub-type.
dal::homogen_table table1 = homogen_table::wrap(queue, data_ptr, row_count, column_
↳count);

// table1 and table2 share the same data (no data copy is performed)
dal::table table2 = table1;

// Creating an empty table
dal::table table3;

std::cout << table1.get_kind()      == table2.get_kind() << std::endl; // true
std::cout << homogen_table::kind() == table2.get_kind() << std::endl; // true
std::cout << table2.get_kind()     == table3.get_kind() << std::endl; // false

// Referring table3 to the table2.
table3 = table2;
std::cout << table2.get_kind() == table3.get_kind() << std::endl; // true
```

Table types

oneDAL defines a set of classes that implement the *table* concept for a specific data format:

Table type	Description
<i>homogen table</i>	A dense table that contains <i>contiguous homogeneous</i> data.

Programming interface

All types and functions in this section shall be declared in the `oneapi::dal` namespace and be available via inclusion of the `oneapi/dal/table/common.hpp` header file.

Table

A base implementation of the *table* concept. The `table` type and all of its subtypes shall be *reference-counted*:

1. The instance shall store a pointer to table implementation that holds all property values and data
2. The reference count indicating how many table objects refer to the same implementation.
3. The table shall increment the reference count for it to be equal to the number of table objects sharing the same implementation.
4. The table shall decrement the reference count when the table goes out of the scope. If the reference count is zero, the table shall free its implementation.

```
class table {
public:
    table();

    table(const table& other);

    table(table&& other);

    table& operator=(const table& other);

    table& operator=(table&& other);

    bool has_data() const noexcept;

    std::int64_t get_column_count() const;

    std::int64_t get_row_count() const;

    const table_metadata& get_metadata() const;

    std::int64_t get_kind() const;

    data_layout get_data_layout() const;
};
```

class **table**

Constructors

`table()`

An empty table constructor: creates the table instance with zero number of rows and columns. Implementation shall be set to the special “empty” object that returns all the property values set to default (see Properties section).

`table(const table &other)`

Creates a new table instance which shares implementation with *other*.

`table(table &&other)`

Creates a new table instance and moves implementation from *other* into it.

Public Methods

`table &operator=(const table &other)`

Replaces the implementation by another one from *other*.

table &operator=(*table* &&other)

Swaps the implementation of this object and *other*.

bool **has_data**() const noexcept

Indicates whether a table contains non-zero number of rows and columns.

std::int64_t **get_column_count**() const

The number of columns in the table.

std::int64_t **get_row_count**() const

The number of rows in the table.

const *table_metadata* &**get_metadata**() const

The metadata object that holds additional information about the data within the table.

std::int64_t **get_kind**() const

The runtime id of the table type. Each table sub-type shall have its unique *kind*. An empty table (see the default constructor) shall have a unique *kind* value as well.

data_layout **get_data_layout**() const

The layout of the data within the table.

Table metadata

An implementation of the *table metadata* concept. Holds additional information about data within the table. The objects of *table_metadata* shall be *reference-counted*.

```
class table_metadata {
public:
    table_metadata();

    table_metadata(const array<data_type>& dtypes, const array<feature_type>& ftypes);

    std::int64_t get_feature_count() const;

    const feature_type& get_feature_type(std::int64_t feature_index) const;

    const data_type& get_data_type(std::int64_t feature_index) const;
};
```

class **table_metadata**

Constructors

table_metadata()

Creates the metadata instance without information about the features. The *feature_count* shall be set to zero. The *data_type* and *feature_type* properties shall not be initialized.

table_metadata(const *array*<*data_type*> &dtypes, const *array*<*feature_type*> &ftypes)

Creates the metadata instance from external information about the data types and the feature types.

Parameters

- **dtypes** – The data types of the features. Shall be assigned into the *data_type* property.
- **ftypes** – The feature types. Shall be assigned into the *feature_type* property.

Preconditions

dtypes.get_count() == *ftypes.get_count*()

Public Methods

`std::int64_t get_feature_count() const`

The number of features that metadata contains information about.

Preconditions

`feature_count >= 0`

`const feature_type &get_feature_type(std::int64_t feature_index) const`

Feature types in the metadata object. Shall be within the range $[0, feature_count)$.

`const data_type &get_data_type(std::int64_t feature_index) const`

Data types of the features in the metadata object. Shall be within the range $[0, feature_count)$.

Data layout

An implementation of the *data layout* concept.

```
enum class data_layout { unknown, row_major, column_major };
```

enum class **data_layout**

data_layout::unknown Represents the *data layout* that is undefined or unknown at this moment.

data_layout::row_major The data block elements are stored in row-major layout.

data_layout::column_major The data block elements are stored in column-major layout.

Feature type

An implementation of the logical data types.

```
enum class feature_type { nominal, ordinal, interval, ratio };
```

enum class **feature_type**

feature_type::nominal Represents the type of *Nominal feature*.

feature_type::ordinal Represents the type of *Ordinal feature*.

feature_type::interval Represents the type of *Interval feature*.

feature_type::ratio Represents the type of *Ratio feature*.

Homogeneous table

Class `homogen_table` is an implementation of a table type for which the following is true:

- The data within the table are dense and stored as one contiguous memory block.
- All the columns have the same *data type*.

Programming interface

All types and functions in this section shall be declared in the `oneapi::dal` namespace and be available via inclusion of the `oneapi/dal/table/homogen.hpp` header file.

```
class homogen_table : public table {
public:
    static std::int64_t kind();

    template <typename Data>
    static homogen_table wrap(const sycl::queue& queue,
                             const Data* data_pointer,
                             std::int64_t row_count,
                             std::int64_t column_count,
                             const sycl::vector_class<sycl::event>& dependencies = {},
                             data_layout layout = data_layout::row_major);

public:
    homogen_table();

    template <typename Data, typename ConstDeleter>
    homogen_table(const sycl::queue& queue,
                 const Data* data_pointer,
                 std::int64_t row_count,
                 std::int64_t column_count,
                 ConstDeleter&& data_deleter,
                 const sycl::vector_class<sycl::event>& dependencies = {},
                 data_layout layout = data_layout::row_
↪major);

    template <typename Data>
    const Data* get_data() const {
        return reinterpret_cast<const Data*>(this->get_data());
    }

    const void* get_data() const;

    std::int64_t get_kind() const {
        return kind();
    }
};
```

class **homogen_table**

Public Static Methods

static `std::int64_t` **kind()**

Returns the unique id of *homogen_table* class.

template<typename **Data**>

static *homogen_table* **wrap**(const sycl::queue &queue, const *Data* *data_pointer, std::int64_t row_count, std::int64_t column_count, const sycl::vector_class<sycl::event> &dependencies = {}, *data_layout* layout = *data_layout::row_major*)

Creates a new *homogen_table* instance from externally-defined data block. Table object refers to the data but does not own it. The responsibility to free the data remains on the user side. The data shall point to the *data_pointer* memory block.

Template Parameters Data – The type of elements in the data block that will be stored into the table. The table shall initialize data types of metadata with this data type. The feature types shall be set to default values for *Data* type: contiguous for floating-point, ordinal for integer types. The *Data* type shall be at least `float`, `double` or `std::int32_t`.

Parameters

- **queue** – The SYCL* queue object.
- **data_pointer** – The pointer to a homogeneous data block.
- **row_count** – The number of rows in the table.
- **column_count** – The number of columns in the table.
- **dependencies** – Events indicating availability of the *data* for reading or writing.
- **layout** – The layout of the data. Shall be `data_layout::row_major` or `data_layout::column_major`.

Constructors

`homogen_table()`

Creates a new *homogen_table* instance with zero number of rows and columns. The *kind* shall be set to `homogen_table::kind()`. All the properties shall be set to default value (see the Properties section).

template<typename **Data**, typename **ConstDeleter**>

homogen_table(const sycl::queue &queue, const *Data* *data_pointer, std::int64_t row_count, std::int64_t column_count, *ConstDeleter* &&data_deleter, const sycl::vector_class<sycl::event> &dependencies = {}, *data_layout* layout = `data_layout::row_major`)

Creates a new *homogen_table* instance from externally-defined data block. Table object owns the data pointer. The data shall point to the *data_pointer* memory block.

Template Parameters

- **Data** – The type of elements in the data block that will be stored into the table. The *Data* type shall be at least `float`, `double` or `std::int32_t`.
- **ConstDeleter** – The type of a deleter called on *data_pointer* when the last table that refers it is out of the scope.

Parameters

- **queue** – The SYCL* queue object.
- **data_pointer** – The pointer to a homogeneous data block.
- **row_count** – The number of rows in the table.
- **column_count** – The number of columns in the table.
- **data_deleter** – The deleter that is called on the *data_pointer* when the last table that refers it is out of the scope.
- **dependencies** – Events indicating availability of the *data* for reading or writing.
- **layout** – The layout of the data. Shall be `data_layout::row_major` or `data_layout::column_major`.

Public Methods

template<typename **Data**>

const *Data* ***get_data**() const

Returns the data pointer cast to the *Data* type. No checks are performed that this type is the actual type of the data within the table.

const void ***get_data**() const

The pointer to the data block within the table. Shall be equal to *nullptr* when `row_count == 0` and `column_count == 0`.

std::int64_t **get_kind**() const

The unique id of the homogen table type.

8.7 Algorithms

The Algorithms component consists of classes that implement algorithms for data analysis (data mining) and data modeling (training and prediction). These algorithms include matrix decompositions, clustering, classification, and regression algorithms, as well as association rules discovery.

8.7.1 Clustering

K-Means

The K-Means algorithm solves *clustering* problem by partitioning n feature vectors into k clusters minimizing some criterion. Each cluster is characterized by a representative point, called a *centroid*.

Operation	Computational methods	Programming Interface		
<i>Training</i>	<i>Lloyd's</i>	<i>train(...)</i>	<i>train_input</i>	<i>train_result</i>
<i>Inference</i>	<i>Lloyd's</i>	<i>infer(...)</i>	<i>infer_input</i>	<i>infer_result</i>

Mathematical formulation

Training

Given the training set $X = \{x_1, \dots, x_n\}$ of p -dimensional feature vectors and a positive integer k , the problem is to find a set $C = \{c_1, \dots, c_k\}$ of p -dimensional centroids that minimize the objective function

$$\Phi_X(C) = \sum_{i=1}^n d^2(x_i, C),$$

where $d^2(x_i, C)$ is the squared Euclidean distance from x_i to the closest centroid in C ,

$$d^2(x_i, C) = \min_{1 \leq j \leq k} \|x_i - c_j\|^2, \quad 1 \leq i \leq n.$$

Expression $\|\cdot\|$ denotes L_2 norm.

Note: In the general case, d may be an arbitrary distance function. Current version of the oneDAL spec defines only Euclidean distance case.

Training method: Lloyd's

The Lloyd's method [Lloyd82] consists in iterative updates of centroids by applying the alternating *Assignment* and *Update* steps, where t denotes a index of the current iteration, e.g., $C^{(t)} = \{c_1^{(t)}, \dots, c_k^{(t)}\}$ is the set of centroids at the t -th iteration. The method requires the initial centroids $C^{(1)}$ to be specified at the beginning of the algorithm ($t = 1$).

(1) Assignment step: Assign each feature vector x_i to the nearest centroid. $y_i^{(t)}$ denotes the assigned label (cluster index) to the feature vector x_i .

$$y_i^{(t)} = \arg \min_{1 \leq j \leq k} \|x_i - c_j^{(t)}\|^2, \quad 1 \leq i \leq n.$$

Each feature vector from the training set X is assigned to exactly one centroid so that X is partitioned to k disjoint sets (clusters)

$$S_j^{(t)} = \{x_i \in X : y_i^{(t)} = j\}, \quad 1 \leq j \leq k.$$

(2) Update step: Recalculate centroids by averaging feature vectors assigned to each cluster.

$$c_j^{(t+1)} = \frac{1}{|S_j^{(t)}|} \sum_{x \in S_j^{(t)}} x, \quad 1 \leq j \leq k.$$

The steps (1) and (2) are performed until the following **stop condition**,

$$\sum_{j=1}^k \|c_j^{(t)} - c_j^{(t+1)}\|^2 < \varepsilon,$$

is satisfied or number of iterations exceeds the maximal value T defined by the user.

Inference

Given the inference set $X' = \{x'_1, \dots, x'_m\}$ of p -dimensional feature vectors and the set $C = \{c_1, \dots, c_k\}$ of centroids produced at the training stage, the problem is to predict the index $y'_j \in \{0, \dots, k - 1\}$, $1 \leq j \leq m$, of the centroid in accordance with a method-defined rule.

Inference method: Lloyd's

Lloyd's inference method computes the y'_j as an index of the centroid closest to the feature vector x'_j ,

$$y'_j = \arg \min_{1 \leq l \leq k} \|x'_j - c_l\|^2, \quad 1 \leq j \leq m.$$

Usage example**Training**

```
kmeans::model<> run_training(const table& data,
                           const table& initial_centroids) {
  const auto kmeans_desc = kmeans::descriptor<float>{}
  .set_cluster_count(10)
  .set_max_iteration_count(50)
```

(continues on next page)

(continued from previous page)

```

        .set_accuracy_threshold(1e-4);

    const auto result = train(kmeans_desc, data, initial_centroids);

    print_table("labels", result.get_labels());
    print_table("centroids", result.get_model().get_centroids());
    print_value("objective", result.get_objective_function_value());

    return result.get_model();
}

```

Inference

```

table run_inference(const kmeans::model<>& model,
                   const table& new_data) {
    const auto kmeans_desc = kmeans::descriptor<float>{}
        .set_cluster_count(model.get_cluster_count());

    const auto result = infer(kmeans_desc, model, new_data);

    print_table("labels", result.get_labels());
}

```

Programming Interface

All types and functions in this section shall be declared in the `oneapi::dal::kmeans` namespace and be available via inclusion of the `oneapi/dal/algo/kmeans.hpp` header file.

Descriptor

```

template <typename Float = float,
          typename Method = method::by_default,
          typename Task = task::by_default>
class descriptor {
public:
    explicit descriptor(std::int64_t cluster_count = 2);

    int64_t get_cluster_count() const;
    descriptor& set_cluster_count(int64_t);

    int64_t get_max_iteration_count() const;
    descriptor& set_max_iteration_count(int64_t);

    double get_accuracy_threshold() const;
    descriptor& set_accuracy_threshold(double);
};

```

```
template<typename Float = float, typename Method = method::by_default, typename Task = task::by_default>
```

class **descriptor**

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be `float` or `double`.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::lloyd`.
- **Task** – Tag-type that specifies the type of the problem to solve. Can be `task::clustering`.

Constructors

descriptor(std::int64_t cluster_count = 2)

Creates a new instance of the class with the given `cluster_count`.

Properties

int64_t **cluster_count**

The number of clusters k . **Default value:** 2.

Getter & Setter

```
int64_t get_cluster_count() const
descriptor & set_cluster_count(int64_t)
```

Invariants

cluster_count > 0

double **accuracy_threshold**

The threshold ε for the stop condition. **Default value:** 0.0.

Getter & Setter

```
double get_accuracy_threshold() const
descriptor & set_accuracy_threshold(double)
```

Invariants

accuracy_threshold >= 0.0

int64_t **max_iteration_count**

The maximum number of iterations T . **Default value:** 100.

Getter & Setter

```
int64_t get_max_iteration_count() const
descriptor & set_max_iteration_count(int64_t)
```

Invariants

max_iteration_count >= 0

Method tags

```
namespace method {
    struct lloyd {};
    using by_default = lloyd;
} // namespace method
```

struct **lloyd**
Tag-type that denotes *Lloyd's* computational method.

using **by_default** = *lloyd*
Alias tag-type for *Lloyd's* computational method.

Task tags

```
namespace task {
    struct clustering {};
    using by_default = clustering;
} // namespace task
```

struct **clustering**
Tag-type that parameterizes entities used for solving *clustering problem*.

using **by_default** = *clustering*
Alias tag-type for the clustering task.

Model

```
template <typename Task = task::by_default>
class model {
public:
    model();

    const table& get_centroids() const;

    int64_t get_cluster_count() const;
};
```

template<typename **Task** = *task::by_default*>
class **model**

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be *task::clustering*.

Constructors

model()
Creates a new instance of the class with the default property values.

Public Methods

const *table* &**get_centroids()** const
A $k \times p$ table with the cluster centroids. Each row of the table stores one centroid.

```
int64_t get_cluster_count() const
    Number of clusters  $k$  in the trained model.
```

Training `train(...)`

Input

```
template <typename Task = task::by_default>
class train_input {
public:
    train_input(const table& data = table{},
               const table& initial_centroids = table{});

    const table& get_data() const;
    train_input& set_data(const table&);

    const table& get_initial_centroids() const;
    train_input& set_initial_centroids(const table&);
};
```

```
template<typename Task = task::by_default>
class train_input
```

Template Parameters `Task` – Tag-type that specifies type of the problem to solve. Can be `task::clustering`.

Constructors

`train_input`(const *table* &data = *table*{}, const *table* &initial_centroids = *table*{})
Creates a new instance of the class with the given data and `initial_centroids`.

Properties

const *table* &data

An $n \times p$ table with the data to be clustered, where each row stores one feature vector.

Getter & Setter

```
const table & get_data() const
train_input & set_data(const table &)
```

const *table* &initial_centroids

A $k \times p$ table with the initial centroids, where each row stores one centroid.

Getter & Setter

```
const table & get_initial_centroids() const
train_input & set_initial_centroids(const table &)
```

Result

```
template <typename Task = task::by_default>
class train_result {
public:
    train_result();

    const model<Task>& get_model() const;

    const table& get_labels() const;

    int64_t get_iteration_count() const;

    double get_objective_function_value() const;
};
```

```
template<typename Task = task::by_default>
class train_result
```

Template Parameters **Task** – Tag-type that specifies type of the problem to solve. Can be `task::clustering`.

Constructors

`train_result()`

Creates a new instance of the class with the default property values.

Public Methods

const *model*<Task> &`get_model()` const

The trained K-means model.

const *table* &`get_labels()` const

An $n \times 1$ table with the labels y_i assigned to the samples x_i in the input data, $1 \leq i \leq n$.

int64_t `get_iteration_count()` const

The number of iterations performed by the algorithm.

double `get_objective_function_value()` const

The value of the objective function $\Phi_X(C)$, where C is `model.centroids` (see `kmeans::model::centroids`).

Operation

```
template <typename Float, typename Method, typename Task>
train_result<Task> train(const descriptor<Float, Method, Task>& desc,
                       const train_input<Task>& input);
```

```
template<typename Float, typename Method, typename Task>
```

```
train_result<Task> train(const descriptor<Float, Method, Task> &desc, const train_input<Task> &input)
```

Runs the training operation for K-Means clustering. For more details see `oneapi::dal::train`.

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be float or double.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::loyd`.

- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::clustering`.

Parameters

- **desc** – Descriptor of the algorithm.
- **input** – Input data for the training operation.

Preconditions

```
input.data.has_data == true
input.initial_centroids.row_count == desc.cluster_count
input.initial_centroids.column_count == input.data.column_count
```

Postconditions

```
result.labels.row_count == input.data.row_count
result.labels.column_count == 1
result.labels[i] >= 0
result.labels[i] < desc.cluster_count
result.iteration_count <= desc.max_iteration_count
result.model.centroids.row_count == desc.cluster_count
result.model.centroids.column_count == input.data.column_count
```

Inference `infer(...)`

Input

```
template <typename Task = task::by_default>
class infer_input {
public:
    infer_input(const model<Task>& m = model<Task>{},
               const table& data = table{});

    const model<Task>& get_model() const;
    infer_input& set_model(const model<Task>&);

    const table& get_data() const;
    infer_input& set_data(const table&);
};
```

```
template<typename Task = task::by_default>
class infer_input
```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::clustering`.

Constructors

infer_input(const *model*<Task> &m = *model*<Task>{}, const *table* &data = *table*{})
Creates a new instance of the class with the given model and data.

Properties

const *table* &**data**
The trained K-Means model. **Default value:** `table{}`.

Getter & Setter

```
const table & get_data() const
infer_input & set_data(const table &)
```

```
const model<Task> &model
```

An $n \times p$ table with the data to be assigned to the clusters, where each row stores one feature vector. **Default value:** `model<Task>{}`.

Getter & Setter

```
const model< Task > & get_model() const
infer_input & set_model(const model< Task > &)
```

Result

```
template <typename Task = task::by_default>
class infer_result {
public:
    infer_result();

    const table& get_labels() const;

    double get_objective_function_value() const;
};
```

```
template<typename Task = task::by_default>
class infer_result
```

Template Parameters **Task** – Tag-type that specifies type of the problem to solve. Can be `task::clustering`.

Constructors**infer_result()**

Creates a new instance of the class with the default property values.

Public Methods

```
const table &get_labels() const
```

An $n \times 1$ table with assignments labels to feature vectors in the input data.

```
double get_objective_function_value() const
```

The value of the objective function $\Phi_X(C)$, where C is defined by the corresponding `infer_input::model::centroids`.

Operation

```
template <typename Float, typename Method, typename Task>
infer_result<Task> infer(const descriptor<Float, Method, Task>& desc,
                       const infer_input<Task>& input);
```

```
template<typename Float, typename Method, typename Task>
```

```
infer_result<Task> infer(const descriptor<Float, Method, Task> &desc, const infer_input<Task> &input)
```

Runs the inference operation for K-Means clustering. For more details see `oneapi::dal::infer`.

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be float or double.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::lloyd`.
- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::clustering`.

Parameters

- **desc** – Descriptor of the algorithm.
- **input** – Input data for the inference operation.

Preconditions

```

.data.has_data == true
.model.centroids.has_data == true
.model.centroids.row_count == desc.cluster_count
.model.centroids.column_count == input.data.column_count

```

Postconditions

```

result.labels.row_count == input.data.row_count
result.labels.column_count == 1
result.labels[i] >= 0
result.labels[i] < desc.cluster_count

```

K-Means initialization

The K-Means initialization algorithm receives n feature vectors as input and chooses k initial centroids. After initialization, K-Means algorithm uses the initialization result to partition input data into k clusters.

Operation	Computational methods	Programming Interface		
<i>Computing</i>	<i>Dense</i>	<i>compute(...)</i>	<i>compute_input</i>	<i>compute_result</i>

Mathematical formulation

Computing

Given the training set $X = \{x_1, \dots, x_n\}$ of p -dimensional feature vectors and a positive integer k , the problem is to find a set $C = \{c_1, \dots, c_k\}$ of p -dimensional initial centroids.

Computing method: *dense*

The method chooses first k feature vectors from the training set X .

Usage example

Computing

```

table run_compute(const table& data) {
    const auto kmeans_desc = kmeans_init::descriptor<float,
                                kmeans_init::method::dense>{}

        .set_cluster_count(10)

    const auto result = compute(kmeans_desc, data);

    print_table("centroids", result.get_centroids());

    return result.get_centroids();
}

```

Programming Interface

All types and functions in this section shall be declared in the `oneapi::dal::kmeans_init` namespace and be available via inclusion of the `oneapi/dal/algo/kmeans_init.hpp` header file.

Descriptor

```

template <typename Float = float,
          typename Method = method::by_default,
          typename Task = task::by_default>
class descriptor {
public:

    explicit descriptor(std::int64_t cluster_count = 2);

    std::int64_t get_cluster_count() const;
    descriptor& set_cluster_count(std::int64_t);

};

```

```

template<typename Float = float, typename Method = method::by_default, typename Task = task::by_default>
class descriptor

```

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be `float` or `double`.
- **Method** – Tag-type that specifies an implementation of K-Means Initialization algorithm.
- **Task** – Tag-type that specifies the type of the problem to solve. Can be `task::init`.

Constructors

```
descriptor(std::int64_t cluster_count = 2)
```

Creates a new instance of the class with the given `cluster_count`.

Properties

std::int64_t **cluster_count**

The number of clusters k . **Default value:** 2.

Getter & Setter

```
std::int64_t get_cluster_count() const
descriptor & set_cluster_count(std::int64_t)
```

Invariants

$cluster_count > 0$

Method tags

```
namespace method {
    struct dense {};
    using by_default = dense;
} // namespace method
```

struct **dense**

Tag-type that denotes *dense* computational method.

using **by_default** = *dense*

Task tags

```
namespace task {
    struct init {};
    using by_default = init;
} // namespace task
```

struct **init**

Tag-type that parameterizes entities used for obtaining the initial K-Means centroids.

using **by_default** = *init*

Alias tag-type for the initialization task.

Computing `compute(...)`

Input

```
template <typename Task = task::by_default>
class compute_input {
public:

    compute_input(const table& data = table{});

    const table& get_data() const;
    compute_input& set_data(const table&);
};
```

```
template<typename Task = task::by_default>
class compute_input
```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::init`.

Constructors

`compute_input`(const *table* &data = *table*{})
Creates a new instance of the class with the given data.

Properties

const *table* &data
An $n \times p$ table with the data to be clustered, where each row stores one feature vector. **Default value:** `table{}`.

Getter & Setter

const *table* & get_data() const
compute_input & set_data(const *table* &)

Result

```
template <typename Task = task::by_default>
class compute_result {
public:

    compute_result();

    const table& get_centroids() const;
};
```

```
template<typename Task = task::by_default>
class compute_result
```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::clustering`.

Constructors

`compute_result`()
Creates a new instance of the class with the default property values.

Public Methods

const *table* &get_centroids() const
A $k \times p$ table with the initial centroids. Each row of the table stores one centroid.

Operation

```
template <typename Float, typename Method, typename Task>
compute_result<Task> compute(const descriptor<Float, Method, Task>& desc,
                             const compute_input<Task>& input);
```

```
template<typename Float, typename Method, typename Task>
compute_result<Task> compute(const descriptor<Float, Method, Task> &desc, const compute_input<Task>
                             &input)
Runs the computing operation for K-Means initialization. For more details, see oneapi::dal::compute.
```

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be `float` or `double`.
- **Method** – Tag-type that specifies an implementation of K-Means Initialization algorithm.
- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::init`.

Parameters

- **desc** – The descriptor of the algorithm.
- **input** – Input data for the computing operation.

Preconditions

```
input.data.has_data == true
input.data.row_count == desc.cluster_count
```

Postconditions

```
result.centroids.has_data == true
result.centroids.row_count == desc.cluster_count
result.centroids.column_count == input.data.column_count
```

8.7.2 Nearest Neighbors (kNN)

k-Nearest Neighbors Classification (k-NN)

k-NN *classification* algorithm infers the class for the new feature vector by computing majority vote of the *k* nearest observations from the training set.

Operation	Computational methods		Programming Interface		
<i>Training</i>	<i>Brute-force</i>	<i>k-d tree</i>	<i>train(...)</i>	<i>train_input</i>	<i>train_result</i>
<i>Inference</i>	<i>Brute-force</i>	<i>k-d tree</i>	<i>infer(...)</i>	<i>infer_input</i>	<i>infer_result</i>

Mathematical formulation

Training

Let $X = \{x_1, \dots, x_n\}$ be the training set of p -dimensional feature vectors, let $Y = \{y_1, \dots, y_n\}$ be the set of class labels, where $y_i \in \{0, \dots, c - 1\}$, $1 \leq i \leq n$. Given X , Y and the number of nearest neighbors k , the problem is to build a model that allows distance computation between the feature vectors in training and inference sets at the inference stage.

Training method: *brute-force*

The training operation produces the model that stores all the feature vectors from the initial training set X .

Training method: *k-d tree*

The training operation builds a k - d tree that partitions the training set X (for more details, see *k-d Tree*).

Inference

Let $X' = \{x'_1, \dots, x'_m\}$ be the inference set of p -dimensional feature vectors. Given X' , the model produced at the training stage and the number of nearest neighbors k , the problem is to predict the label y'_j for each x'_j , $1 \leq j \leq m$, by performing the following steps:

1. Identify the set $N(x'_j) \subseteq X$ of the k feature vectors in the training set that are nearest to x'_j with respect to the Euclidean distance.
2. Estimate the conditional probability for the l -th class as the fraction of vectors in $N(x'_j)$ whose labels y_j are equal to l :

$$P_{jl} = \frac{1}{|N(x'_j)|} \left| \{x_r \in N(x'_j) : y_r = l\} \right|, \quad 1 \leq j \leq m, \quad 0 \leq l < c. \quad (8.1)$$

3. Predict the class that has the highest probability for the feature vector x'_j :

$$y'_j = \arg \max_{0 \leq l < c} P_{jl}, \quad 1 \leq j \leq m. \quad (8.2)$$

Inference method: *brute-force*

Brute-force inference method determines the set $N(x'_j)$ of the nearest feature vectors by iterating over all the pairs (x'_j, x_i) in the implementation defined order, $1 \leq i \leq n$, $1 \leq j \leq m$. The final prediction is computed according to the equations (8.1) and (8.2).

Inference method: *k-d tree*

K - d tree inference method traverses the k - d tree to find feature vectors associated with a leaf node that are closest to x'_j , $1 \leq j \leq m$. The set $\tilde{n}(x'_j)$ of the currently-known nearest k -th neighbors is progressively updated during tree traversal. The search algorithm limits exploration of the nodes for which the distance between the x'_j and respective part of the feature space is not less than the distance between x'_j and the most distant feature vector from $\tilde{n}(x'_j)$. Once tree traversal is finished, $\tilde{n}(x'_j) \equiv N(x'_j)$. The final prediction is computed according to the equations (8.1) and (8.2).

Usage example

Training

```
knn::model<> run_training(const table& data,
                        const table& labels) {
    const std::int64_t class_count = 10;
    const std::int64_t neighbor_count = 5;
    const auto knn_desc = knn::descriptor<float>{class_count, neighbor_count};

    const auto result = train(knn_desc, data, labels);

    return result.get_model();
}
```

Inference

```
table run_inference(const knn::model<>& model,
                   const table& new_data) {
    const std::int64_t class_count = 10;
    const std::int64_t neighbor_count = 5;
    const auto knn_desc = knn::descriptor<float>{class_count, neighbor_count};

    const auto result = infer(knn_desc, model, new_data);

    print_table("labels", result.get_labels());
}
```

Programming Interface

All types and functions in this section shall be declared in the `oneapi::dal::knn` namespace and be available via inclusion of the `oneapi/dal/alg/knn.hpp` header file.

Descriptor

```
template <typename Float = float,
         typename Method = method::by_default,
         typename Task = task::by_default>
class descriptor {
public:
    explicit descriptor(std::int64_t class_count,
                      std::int64_t neighbor_count);

    std::int64_t get_class_count() const;
    descriptor& set_class_count(std::int64_t);

    std::int64_t get_neighbor_count() const;
```

(continues on next page)

(continued from previous page)

```
descriptor& set_neighbor_count(std::int64_t);
};
```

```
template<typename Float = float, typename Method = method::by_default, typename Task = task::by_default>
class descriptor
```

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be float or double.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::bruteforce` or `method::kd_tree`.
- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::classification`.

Constructors

```
descriptor(std::int64_t class_count, std::int64_t neighbor_count)
```

Creates a new instance of the class with the given `class_count` and `neighbor_count` property values.

Properties

```
std::int64_t class_count
```

The number of classes *c*.

Getter & Setter

```
std::int64_t get_class_count() const
descriptor & set_class_count(std::int64_t)
```

Invariants

```
class_count > 1
```

```
std::int64_t neighbor_count
```

The number of neighbors *k*.

Getter & Setter

```
std::int64_t get_neighbor_count() const
descriptor & set_neighbor_count(std::int64_t)
```

Invariants

```
neighbor_count > 0
```

Method tags

```
namespace method {
    struct bruteforce {};
    struct kd_tree {};
    using by_default = bruteforce;
} // namespace method
```

```
struct bruteforce
```

Tag-type that denotes *brute-force* computational method.

```
struct kd_tree
    Tag-type that denotes k-d tree computational method.
using by_default = bruteforce
    Alias tag-type for brute-force computational method.
```

Task tags

```
namespace task {
    struct classification {};
    using by_default = classification;
} // namespace task
```

```
struct classification
    Tag-type that parameterizes entities used for solving classification problem.
using by_default = classification
    Alias tag-type for classification task.
```

Model

```
template <typename Task = task::by_default>
class model {
public:
    model();
};
```

```
template<typename Task = task::by_default>
class model
```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::classification`.

Constructors

model()
Creates a new instance of the class with the default property values.

Training `train(...)`

Input

```
template <typename Task = task::by_default>
class train_input {
public:
    train_input(const table& data = table{},
                const table& labels = table{});

    const table& get_data() const;
    train_input& set_data(const table&);
```

(continues on next page)

(continued from previous page)

```

const table& get_labels() const;
train_input& set_labels(const table&);
};

```

```

template<typename Task = task::by_default>
class train_input

```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::classification`.

Constructors

```
train_input(const table &data = table{}, const table &labels = table{})
```

Creates a new instance of the class with the given data and labels property values.

Properties

```
const table &data
```

The training set X . **Default value:** `table{}`.

Getter & Setter

```

const table & get_data() const
train_input & set_data(const table &)

```

```
const table &labels
```

Vector of labels y for the training set X . **Default value:** `table{}`.

Getter & Setter

```

const table & get_labels() const
train_input & set_labels(const table &)

```

Result

```

template <typename Task = task::by_default>
class train_result {
public:
    train_result();

    const model<Task>& get_model() const;
};

```

```

template<typename Task = task::by_default>
class train_result

```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::classification`.

Constructors

```
train_result()
```

Creates a new instance of the class with the default property values.

Public Methods

```
const model<Task> &get_model() const
```

The trained k -NN model.

Operation

```
template <typename Float, typename Method, typename Task>
train_result<Task> train(const descriptor<Float, Method, Task>& desc,
                       const train_input<Task>& input);
```

```
template<typename Float, typename Method, typename Task>
train_result<Task> train(const descriptor<Float, Method, Task> &desc, const train_input<Task> &input)
    Runs the training operation for  $k$ -NN classifier. For more details see oneapi::dal::train.
```

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be float or double.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::bruteforce` or `method::kd_tree`.
- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::classification`.

Parameters

- **desc** – Descriptor of the algorithm.
- **input** – Input data for the training operation.

Preconditions

```
input.data.has_data == true
input.labels.has_data == true
input.data.row_count == input.labels.row_count
input.labels.column_count == 1
input.labels[i] >= 0
input.labels[i] < desc.class_count
```

Inference infer(...)

Input

```
template <typename Task = task::by_default>
class infer_input {
public:
    infer_input(const model<Task>& m = model<Task>{},
               const table& data = table{});

    const model<Task>& get_model() const;
    infer_input& set_model(const model&);

    const table& get_data() const;
    infer_input& set_data(const table&);
};
```

```
template<typename Task = task::by_default>
class infer_input
```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::classification`.

Constructors

infer_input(const *model*<Task> &m = *model*<Task>{}, const *table* &data = *table*{})
Creates a new instance of the class with the given `model` and `data` property values.

Properties

const *table* &**data**
The dataset for inference X' . **Default value:** `table{}`.

Getter & Setter

```
const table & get_data() const
infer_input & set_data(const table &)
```

const *model*<Task> &**model**
The trained k -NN model. **Default value:** `model<Task>{}`.

Getter & Setter

```
const model< Task > & get_model() const
infer_input & set_model(const model &)
```

Result

```
template <typename Task = task::by_default>
class infer_result {
public:
    infer_result();

    const table& get_labels() const;
};
```

```
template<typename Task = task::by_default>
class infer_result
```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::classification`.

Constructors

infer_result()
Creates a new instance of the class with the default property values.

Public Methods

const *table* &**get_labels()** const
The predicted labels.

Operation

```
template <typename Float, typename Method, typename Task>
infer_result<Task> infer(const descriptor<Float, Method, Task>& desc,
                       const infer_input<Task>& input);
```

```
template<typename Float, typename Method, typename Task>
infer_result<Task> infer(const descriptor<Float, Method, Task> &desc, const infer_input<Task> &input)
```

Runs the inference operation for k -NN classifier. For more details see `oneapi::dal::infer`.

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be float or double.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::bruteforce` or `method::kd_tree`.
- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::classification`.

Parameters

- **desc** – Descriptor of the algorithm.
- **input** – Input data for the inference operation.

Preconditions

```
input.data.has_data == true
```

Postconditions

```
result.labels.row_count == input.data.row_count
result.labels.column_count == 1
result.labels[i] >= 0
result.labels[i] < desc.class_count
```

8.7.3 Decomposition

Principal Components Analysis (PCA)

Principal Component Analysis (PCA) is an algorithm for exploratory data analysis and *dimensionality reduction*. PCA transforms a set of feature vectors of possibly correlated features to a new set of uncorrelated features, called principal components. Principal components are the directions of the largest variance, that is, the directions where the data is mostly spread out.

Operation	Computational methods		Programming Interface		
<i>Training</i>	<i>Covariance</i>	<i>SVD</i>	<i>train(...)</i>	<i>train_input</i>	<i>train_result</i>
<i>Inference</i>	<i>Covariance</i>	<i>SVD</i>	<i>infer(...)</i>	<i>infer_input</i>	<i>infer_result</i>

Mathematical formulation

Training

Given the training set $X = \{x_1, \dots, x_n\}$ of p -dimensional feature vectors and the number of principal components r , the problem is to compute r principal directions (p -dimensional eigenvectors [Lang87]) for the training set. The eigenvectors can be grouped into the $r \times p$ matrix T that contains one eigenvector in each row.

Training method: *Covariance*

This method uses eigenvalue decomposition of the covariance matrix to compute the principal components of the datasets. The method relies on the following steps:

1. Computation of the covariance matrix
2. Computation of the eigenvectors and eigenvalues
3. Formation of the matrices storing the results

Covariance matrix computation shall be performed in the following way:

1. Compute the vector-column of sums $s_i = \sum_{j=1}^n x_{i,j}$, $1 \leq i \leq p$.
2. Compute the cross-product $P = X^T X - s^T s$.
3. Compute the covariance matrix $\Sigma = \frac{1}{n-1} P$.

To compute eigenvalues λ_i and eigenvectors v_i , the implementer can choose an arbitrary method such as [Ping14].

The final step is to sort the set of pairs (λ_i, v_i) in the descending order by λ_i and form the resulting matrix $T = (v_{i,1}, \dots, v_{i,r})$, $1 \leq i \leq p$. Additionally, the means and variances of the initial dataset shall be returned.

Training method: *SVD*

This method uses singular value decomposition of the dataset to compute its principal components. The method relies on the following steps:

1. Computation of the singular values and singular vectors
2. Formation of the matrices storing the results

To compute singular values λ_i and singular vectors u_i and v_i , the implementer can choose an arbitrary method such as [Demmel90].

The final step is to sort the set of pairs (λ_i, v_i) in the descending order by λ_i and form the resulting matrix $T = (v_{i,1}, \dots, v_{i,r})$, $1 \leq i \leq p$. Additionally, the means and variances of the initial dataset shall be returned.

Sign-flip technique

Eigenvectors computed by some eigenvalue solvers are not uniquely defined due to sign ambiguity. To get the deterministic result, a sign-flip technique should be applied. One of the sign-flip techniques proposed in [Bro07] requires the following modification of matrix T :

$$\hat{T}_i = T_i \cdot \operatorname{sgn}\left(\max_{1 \leq j \leq p} |T_{ij}|\right), \quad 1 \leq i \leq r,$$

where T_i is i -th row, T_{ij} is the element in the i -th row and j -th column, $\text{sgn}(\cdot)$ is the signum function,

$$\text{sgn}(x) = \begin{cases} -1, & x < 0, \\ 0, & x = 0, \\ 1, & x > 0. \end{cases}$$

Note: The sign-flip technique described above is an example. oneDAL spec does not require implementation of this sign-flip technique. Implementer can choose an arbitrary technique that modifies the eigenvectors' signs.

Inference

Given the inference set $X' = \{x'_1, \dots, x'_m\}$ of p -dimensional feature vectors and the $r \times p$ matrix T produced at the training stage, the problem is to transform X' to the set $X'' = \{x''_1, \dots, x''_m\}$, where x''_j is an r -dimensional feature vector, $1 \leq j \leq m$.

The feature vector x''_j is computed through applying linear transformation [Lang87] defined by the matrix T to the feature vector x'_j ,

$$x''_j = T x'_j, \quad 1 \leq j \leq m. \quad (8.3)$$

Inference methods: *Covariance* and *SVD*

Covariance and SVD inference methods compute x''_j according to (8.3).

Usage example

Training

```
pca::model<> run_training(const table& data) {
    const auto pca_desc = pca::descriptor<float>{}
        .set_component_count(5)
        .set_deterministic(true);

    const auto result = train(pca_desc, data);

    print_table("means", result.get_means());
    print_table("variances", result.get_variances());
    print_table("eigenvalues", result.get_eigenvalues());
    print_table("eigenvectors", result.get_eigenvectors());

    return result.get_model();
}
```

Inference

```
table run_inference(const pca::model<>& model,
                   const table& new_data) {
    const auto pca_desc = pca::descriptor<float>{}
        .set_component_count(model.get_component_count());

    const auto result = infer(pca_desc, model, new_data);

    print_table("labels", result.get_transformed_data());
}
```

Programming Interface

All types and functions in this section shall be declared in the `oneapi::dal::pca` namespace and be available via inclusion of the `oneapi/dal/algo/pca.hpp` header file.

Descriptor

```
template <typename Float = float,
         typename Method = method::by_default,
         typename Task = task::by_default>
class descriptor {
public:
    explicit descriptor(std::int64_t component_count = 0);

    int64_t get_component_count() const;
    descriptor& set_component_count(int64_t);

    bool get_deterministic() const;
    descriptor& set_deterministic(bool);
};
```

```
template<typename Float = float, typename Method = method::by_default, typename Task = task::by_default>
class descriptor
```

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be `float` or `double`.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::cov` or `method::svd`.
- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::dim_reduction`.

Constructors

descriptor(std::int64_t component_count = 0)

Creates a new instance of the class with the given `component_count` property value.

Properties

int64_t component_count

The number of principal components r . If it is zero, the algorithm computes the eigenvectors for all features, $r = p$. **Default value:** 0.

Getter & Setter

```
int64_t get_component_count() const
descriptor & set_component_count(int64_t)
```

Invariants

```
component_count >= 0
```

bool deterministic

Specifies whether the algorithm applies the *Sign-flip technique*. If it is *true*, the directions of the eigenvectors must be deterministic. **Default value:** true.

Getter & Setter

```
bool get_deterministic() const
descriptor & set_deterministic(bool)
```

Method tags

```
namespace method {
  struct cov {};
  struct svd {};
  using by_default = cov;
} // namespace method
```

struct cov

Tag-type that denotes *Covariance* computational method.

struct svd

Tag-type that denotes *SVD* computational method.

using by_default = cov

Alias tag-type for *Covariance* computational method.

Task tags

```
namespace task {
  struct dim_reduction {};
  using by_default = dim_reduction;
} // namespace task
```

struct dim_reduction

Tag-type that parameterizes entities used for solving *dimensionality reduction problem*.

using by_default = dim_reduction

Alias tag-type for dimensionality reduction task.

Model

```
template <typename Task = task::by_default>
class model {
public:
    model();

    const table& get_eigenvectors() const;

    int64_t get_component_count() const;
};
```

```
template<typename Task = task::by_default>
class model
```

Template Parameters **Task** – Tag-type that specifies type of the problem to solve. Can be `task::dim_reduction`.

Constructors

`model()`

Creates a new instance of the class with the default property values.

Public Methods

`const table& get_eigenvectors() const`

An $r \times p$ table with the eigenvectors. Each row contains one eigenvector.

`int64_t get_component_count() const`

The number of components r in the trained model.

Training `train(...)`

Input

```
template <typename Task = task::by_default>
class train_input {
public:
    train_input(const table& data = table{});

    const table& get_data() const;
    train_input& set_data(const table&);
};
```

```
template<typename Task = task::by_default>
class train_input
```

Template Parameters **Task** – Tag-type that specifies type of the problem to solve. Can be `task::dim_reduction`.

Constructors

`train_input(const table& data = table{})`

Creates a new instance of the class with the given data property value.

Properties

const *table* &data

An $n \times p$ table with the training data, where each row stores one feature vector. **Default value:** table{ }.

Getter & Setter

```
const table & get_data() const
train_input & set_data(const table &)
```

Result

```
template <typename Task = task::by_default>
class train_result {
public:
    train_result();

    const model<Task>& get_model() const;

    const table& get_means() const;

    const table& get_variances() const;

    const table& get_eigenvalues() const;

    const table& get_eigenvectors() const;
};
```

```
template<typename Task = task::by_default>
class train_result
```

Template Parameters **Task** – Tag-type that specifies type of the problem to solve. Can be `task::dim_reduction`.

Constructors

train_result()

Creates a new instance of the class with the default property values.

Public Methods

const *model*<Task> &get_model() const

The trained PCA model.

const *table* &get_means() const

A $1 \times r$ table that contains the mean values for the first r features.

const *table* &get_variances() const

A $1 \times r$ table that contains the variances for the first r features.

const *table* &get_eigenvalues() const

A $1 \times r$ table that contains the eigenvalues for for the first r features.

const *table* &get_eigenvectors() const

An $r \times p$ table with the eigenvectors. Each row contains one eigenvector.

Operation

```
template <typename Float, typename Method, typename Task>
train_result<Task> train(const descriptor<Float, Method, Task>& desc,
                       const train_input<Task>& input);
```

```
template<typename Float, typename Method, typename Task>
train_result<Task> train(const descriptor<Float, Method, Task> &desc, const train_input<Task> &input)
```

Runs the training operation for PCA. For more details, see `oneapi::dal::train`.

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be `float` or `double`.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::cov` or `method::svd`.
- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::dim_reduction`.

Parameters

- **desc** – Descriptor of the algorithm.
- **input** – Input data for the training operation.

Preconditions

```
input.data.has_data == true
input.data.column_count >= desc.component_count
```

Postconditions

```
result.means.row_count == 1
result.means.column_count == desc.component_count
result.variances.row_count == 1
result.variances.column_count == desc.component_count
result.variances[i] >= 0.0
result.eigenvalues.row_count == 1
result.eigenvalues.column_count == desc.component_count
result.model.eigenvectors.row_count == 1
result.model.eigenvectors.column_count == desc.component_count
```

Inference `infer(...)`

Input

```
template <typename Task = task::by_default>
class infer_input {
public:
    infer_input(const model<Task>& m = model<Task>{},
               const table& data = table{});

    const model<Task>& get_model() const;
```

(continues on next page)

(continued from previous page)

```
infer_input& set_model(const model&);

const table& get_data() const;
infer_input& set_data(const table&);
};
```

```
template<typename Task = task::by_default>
class infer_input
```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::dim_reduction`.

Constructors

```
infer_input(const model<Task> &m = model<Task>{}, const table &data = table{})
```

Creates a new instance of the class with the given `model` and `data` property values.

Properties

```
const table &data
```

The dataset for inference X' . **Default value:** `table{}`.

Getter & Setter

```
const table & get_data() const
infer_input & set_data(const table &)
```

```
const model<Task> &model
```

The trained PCA model. **Default value:** `model<Task>{}`.

Getter & Setter

```
const model< Task > & get_model() const
infer_input & set_model(const model &)
```

Result

```
template <typename Task = task::by_default>
class infer_result {
public:
    infer_result();

    const table& get_transformed_data() const;
};
```

```
template<typename Task = task::by_default>
class infer_result
```

Template Parameters Task – Tag-type that specifies type of the problem to solve. Can be `task::dim_reduction`.

Constructors

```
infer_result()
```

Creates a new instance of the class with the default property values.

Public Methods

```
const table &get_transformed_data() const
```

An $n \times r$ table that contains data projected to the r principal components.

Operation

```
template <typename Float, typename Method, typename Task>
infer_result<Task> infer(const descriptor<Float, Method, Task>& desc,
                        const infer_input<Task>& input);
```

```
template<typename Float, typename Method, typename Task>
```

```
infer_result<Task> infer(const descriptor<Float, Method, Task> &desc, const infer_input<Task> &input)
```

Runs the inference operation for PCA. For more details see `oneapi::dal::infer`.

Template Parameters

- **Float** – The floating-point type that the algorithm uses for intermediate computations. Can be `float` or `double`.
- **Method** – Tag-type that specifies an implementation of algorithm. Can be `method::cov` or `method::svd`.
- **Task** – Tag-type that specifies type of the problem to solve. Can be `task::dim_reduction`.

Parameters

- **desc** – Descriptor of the algorithm.
- **input** – Input data for the inference operation.

Preconditions

```
input.data.has_data == true
```

```
input.model.eigenvectors.row_count == desc.component_count
```

```
input.model.eigenvectors.column_count == input.data.column_count
```

Postconditions

```
result.transformed_data.row_count == input.data.row_count
```

```
result.transformed_data.column_count == desc.component_count
```

8.8 Appendix

8.8.1 k-d Tree

k - d tree is a space-partitioning binary tree [Bentley80], where

- Each non-leaf node induces the hyperplane that splits the feature space into two parts. To define the splitting hyperplane explicitly, a non-leaf node stores the identifier of the feature (that defines axis in the feature space) and a *cut-point*
- Each leaf node of the tree has an associated subset (*a bucket*) of elements of the training data set. Feature vectors from a bucket belong to the region of the space defined by tree nodes on the path from the root node to the respective leaf.

Related terms

A **cut-point** A feature value that corresponds to a non-leaf node of a k - d tree and defines the splitting hyperplane orthogonal to the axis specified by the given feature.

8.9 Bibliography

For more information about algorithms implemented in oneAPI Data Analytics Library (oneDAL), refer to the following publications:

9.1 General Information

9.1.1 Introduction

[intro]

This document specifies requirements for implementations of oneAPI Threading Building Blocks (oneTBB).

oneTBB is a programming model for scalable parallel programming using standard ISO C++ code. A program uses oneTBB to specify logical parallelism in algorithms, while a oneTBB implementation maps that parallelism onto execution threads.

oneTBB employs generic programming via C++ templates, with most of its interfaces defined by requirements on types and not specific types. Generic programming makes oneTBB flexible yet efficient through customizing APIs to specific needs of an application.

Here is the list of specific requirements for oneTBB implementations:

- An implementation should use the C++11 version of the standard and should not require newer versions except where explicitly specified; it also should not require any non-standard language extensions.
- An implementation can use platform-specific APIs if they are compatible with the C++ execution and memory models. For example, a platform-specific implementation of threads can be used if that implementation provides the same execution guarantees as C++ threads.
- An implementation should support execution on single-core and multi-core CPUs, including those that provide simultaneous multithreading capabilities.
- On CPU, an implementation should support nested parallelism to enable building larger parallel components from smaller ones.

9.1.2 Notational Conventions

[notational_conventions]

The following conventions are used in this document.

Convention	Explanation	Example
<i>Italic</i>	Used for introducing new terms, denotation of terms, placeholders, or titles of documents.	The filename consists of the <i>base-name</i> and the <i>extension</i> . For more information, refer to the <i>TBB Developer Guide</i> .
Monospace	Indicates directory paths and filenames, commands and command line options, function names, methods, classes, data structures in body text, source code.	oneapi/tbb.h \alt\include Use the okCreateObjs() function to... printf("hello, world\n");
Monospace italic	Indicates source code placeholders.	blocked_range<Type>
Monospace bold	Emphasizes parts of source code.	x = (h > 0 ? sizeof(m) : 0xF) + min;
[]	Square brackets indicate that the items enclosed in brackets are optional.	Fa[c] Indicates Fa or Fac.
{ }	Braces and vertical bars indicate the choice of one item from a selection of two or more items.	X{K W P} Indicates XK, XW, or XP.
“[” “]” “{” “}” “ ”	Writing a metacharacter in quotation marks negates the syntactical meaning stated above; the character is taken as a literal.	“[” X “]” [Y] Denotes the letter X enclosed in brackets, optionally followed by the letter Y.
...	The ellipsis indicates that the previous item can be repeated several times.	filename ... Indicates that one or more filenames can be specified.
,...	The ellipsis preceded by a comma indicates that the previous item can be repeated several times, separated by commas.	word ,... Indicates that one or more words can be specified. If more than one word is specified, the words are comma-separated.

Class members are summarized by informal class declarations that describe the class as it seems to clients, not how it is actually implemented. For example, here is an informal declaration of class Foo:

```
class Foo {
public:
    int x();
    int y;
    ~Foo();
};
```

The actual implementation might look like:

```
namespace internal {
    class FooBase {
    protected:
        int x();
    };

    class Foo_v3: protected FooBase {
    private:
```

(continues on next page)

(continued from previous page)

```
        int internal_stuff;
    public:
        using FooBase::x;
        int y;
};
typedef internal::Foo_v3 Foo;
```

The example shows two cases where the actual implementation departs from the informal declaration:

- Foo is actually a typedef to Foo_v3.
- Method x() is inherited from a protected base class.
- The destructor is an implicit method generated by the compiler.

The informal declarations are intended to show you what you need to know to use the class without the distraction of irrelevant clutter particular to the implementation.

9.1.3 Identifiers

[identifiers]

This section describes the identifier conventions used by oneTBB.

Case

The identifier convention in the library follows the style of the ISO C++ standard library. Identifiers are written in `underscore_style`, and concepts - in `PascalCase`.

Reserved Identifier Prefixes

The library reserves the `__TBB` prefix for internal identifiers and macros that should never be directly referenced by your code.

9.1.4 Named Requirements

[named_requirements]

This section describes named requirements used in the oneTBB Specification.

A *named requirement* is a set of requirements on a type. The requirements may be syntactic or semantic. The *named requirement* term is similar to “Requirements on types and expressions” term which is defined by the ISO C++ Standard (chapter “Library Introduction”) or “[Named Requirements](#)” section on the [cppreference.com](#) site.

For example, the named requirement of *sortable* could be defined as a set of requirements that enable an array to be sorted. A type T would be *sortable* if:

- `x < y` returns a boolean value, and represents a total order on items of type T.
- `swap(x, y)` swaps items x and y

You can write a sorting template function in C++ that sorts an array of any type that is *sortable*.

Two approaches for defining named requirements are *valid expressions* and *pseudo-signatures*. The ISO C++ standard follows the *valid expressions* approach, which shows what the usage pattern looks like for a requirement. It has the drawback of relegating important details to notational conventions. This document uses pseudo-signatures because they are concise and can be cut-and-pasted for an initial implementation.

For example, the table below shows pseudo-signatures for a *sortable* type T:

Sortable Requirements : Pseudo-Signature, Semantics

bool **operator<**(const T &x, const T &y)
Compare x and y.

void **swap**(T &x, T &y)
Swap x and y.

A real signature may differ from the pseudo-signature that it implements in ways where implicit conversions would deal with the difference. For an example type U, the real signature that implements **operator<** in the table above can be expressed as `int operator<(U x, U y)`, because C++ permits implicit conversion from `int` to `bool`, and implicit conversion from U to `(const U&)`. Similarly, the real signature `bool operator<(U& x, U& y)` is acceptable because C++ permits implicit addition of a `const` qualifier to a reference type.

Algorithms

Range

[req.range]

A *Range* can be recursively subdivided into two parts. Subdivision is done by calling *splitting constructor* of a *Range*. There are two types of splitting constructors:

- Basic splitting constructor. In this constructor, it is recommended that the division is done into nearly equal parts, but it is not required. Splitting as evenly as possible typically yields the best parallelism.
- Proportional splitting constructor. This constructor is optional and can be omitted. When using this type of constructor, for the best results, follow the given proportion with rounding to the nearest integer if necessary.

Ideally, a range is recursively splittable until the parts represent portions of work that are more efficient to execute serially rather than split further. The amount of work represented by *Range* typically depends on higher level context, therefore a typical type that models a *Range* should provide a way to control the degree of splitting. For example, the template class *blocked_range* has the *grainsize* parameter that specifies the biggest range considered indivisible.

If the set of values has a sense of direction, by convention the splitting constructor should construct the second part of the range and update its argument to be the first part of the range. This causes the *parallel_for*, *parallel_reduce*, and *parallel_scan* algorithms, when running sequentially, to work across a range in the increasing order, which is typical of an ordinary sequential loop.

Because a *Range* declares splitting and copy constructors, the default constructor for it is not generated automatically. You need to explicitly define the default constructor or add any other constructor to create an instance of a *Range* type in the program.

A type *R* meets *Range* if it satisfies the following requirements:

Range Requirements: Pseudo-Signature, Semantics

R::R(const R&)
Copy constructor.

R::~~R()
Destructor.

bool **R::empty**() const
True if range is empty.

bool **R::is_divisible**() const
True if range can be partitioned into two subranges.

R::R(R &r, split)
Basic splitting constructor. Splits r into two subranges.

R::R(R &r, *proportional_split* proportion)
Optional. Proportional splitting constructor. Splits r into two subranges in accordance with *proportion*.

- *blocked_range2d class*
- *blocked_range3d class*
- *parallel_reduce algorithm*
- *parallel_for algorithm*
- *split class*

Splittable

[req.splittable]

A type is splittable if it has a *splitting constructor* that allows an instance to be split into two pieces. The splitting constructor takes as arguments a reference to the original object, and a dummy argument of type `split`, which is defined by the library. The dummy argument distinguishes the splitting constructor from a copy constructor. After the constructor runs, `x` and the newly constructed object should represent the two pieces of the original `x`. The library uses splitting constructors in two contexts:

- *Partitioning* a range into two subranges that can be processed concurrently.
- *Forking* a body (function object) into two bodies that can run concurrently.

Types that meet the *Range requirements* may additionally define an optional *proportional splitting constructor*, distinguished by an argument of type *proportional_split Class*.

A type *X* satisfies *Splittable* if it meets the following requirements:

Splittable Requirements: Pseudo-Signature, Semantics

X::X(X &x, split)
Split x into x and newly constructed object.

See also:

- *Range requirements*

ParallelForBody

[req.parallel_for_body]

A type *Body* satisfies *ParallelForBody* if it meets the following requirements:

ParallelForBody Requirements: Pseudo-Signature, Semantics

Body : : **Body**(const *Body*&)
Copy constructor.

Body : : **~Body**()
Destructor.

void *Body* : : **operator**() (Range &range) const
Applies body to a range. Range type must meet the *Range requirements*.

See also:

- *parallel_for algorithm*

ParallelForFunc

[req.parallel_for_func]

A type *F* satisfies *ParallelForFunc* if it meets the following requirements:

ParallelForFunc Requirements: Pseudo-Signature, Semantics

void *F* : : **operator**() (Index index) const
Applies the function to the index. Index type must be the same as corresponding template parameter of the *parallel_for algorithm*.

See also:

- *parallel_for algorithm*
- *ParallelForIndex named requirement*

ParallelForIndex

[req.parallel_for_index]

A type *Index* satisfies *ParallelForIndex* if it meets the following requirements:

ParallelForIndex Requirements: Pseudo-Signature, Semantics

Index : : **Index**(int)
Constructor from an int value.

Index : : **Index**(const *Index*&)
Copy constructor.

Index : : **~Index**()
Destructor.

void **operator=**(const Index&)
Assignment.

Note: The return type `void` in the pseudo-signature denotes that `operator=` is not required to return a value. The actual `operator=` can return a value, which will be ignored.

bool **operator<**(const Index &i, const Index &j)
Value of *i* precedes value of *j*.

D **operator-**(const Index &i, const Index &j)
Number of values in range [*i*, *j*).

Index **operator+**(const Index &i, D k)
k-th value after *i*.

D is the type of the expression *j-i*. It can be any integral type that is convertible to `size_t`. Examples that model the Index requirements are integral types and pointers.

See also:

- [parallel_for algorithm](#)

ParallelReduceBody

[req.parallel_reduce_body]

A type *Body* satisfies *ParallelReduceBody* if it meets the following requirements:

ParallelReduceBody Requirements: Pseudo-Signature, Semantics

Body: :**Body**(*Body*&, split)
Splitting constructor. Must be able to run concurrently with `operator()` and method `join`.

Body: :~**Body**()
Destructor.

void *Body*: :**operator()**(const Range &range)
Accumulates result for a subrange. Range type must meet the *Range requirements*.

void *Body*: :**join**(*Body* &rhs)
Joins results. The result in rhs should be merged into the result of `this`.

See also:

- [parallel_reduce algorithm](#)
- [parallel_deterministic_reduce algorithm](#)

ParallelReduceFunc

[req.parallel_reduce_body]

A type *Func* satisfies *ParallelReduceFunc* if it meets the following requirements:

ParallelReduceFunc Requirements: Pseudo-Signature, Semantics

Value *Func* : : **operator**() (const Range &range, const Value &x) const

Accumulates result for a subrange, starting with initial value *x*. Range type must meet the *Range requirements*.

Value type must be the same as a corresponding template parameter for the *parallel_reduce algorithm*.

See also:

- *parallel_reduce algorithm*
- *parallel_deterministic_reduce algorithm*

ParallelReduceReduction

[req.parallel_reduce_reduction]

A type *Reduction* satisfies *ParallelReduceReduction* if it meets the following requirements:

ParallelReduceReduction Requirements: Pseudo-Signature, Semantics

Value *Reduction* : : **operator**() (const Value &x, const Value &y) const

Combines results *x* and *y*. Value type must be the same as a corresponding template parameter for the *parallel_reduce algorithm*.

See also:

- *parallel_reduce algorithm*
- *parallel_deterministic_reduce algorithm*

ParallelForEachBody

[req.parallel_for_each_body]

A type *Body* satisfies *ParallelForBody* if it meets the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard. It should also meet one of the following requirements:

ParallelForEachBody Requirements: Pseudo-Signature, Semantics

Body : : **operator**() (ItemType item) const

Process the received item.

Body : : **operator**() (ItemType item, oneapi::tbb::feeder<ItemType> &feeder) const

Process the received item. May invoke the `feeder.add(T)` function to spawn additional items.

Note: *ItemType* may be optionally passed to *Body* : : **operator**() by reference. `const` and `volatile` type qualifiers are also applicable.

Terms

- `iterator` determines the type of the iterator passed into the `parallel_for_each` algorithm, which is `decltype(std::begin(c))` for the overloads that accept the `Container` template argument or `InputIterator`.
- `value_type` - the type `std::iterator_traits<iterator>::value_type`.
- `reference` - the type `std::iterator_traits<iterator>::reference`.

`oneapi::tbb::parallel_for_each` requires the `Body::operator()` call with an object of the `reference` type to be well-formed if the `iterator` meets the *Forward iterator* requirements described in the [forward.iterators] section of the ISO C++ Standard.

`oneapi::tbb::parallel_for_each` algorithm requires the `Body::operator()` call with an object of type `const value_type&` or `value_type&&` to be well-formed if following requirements are met:

- the iterator meets the *Input iterator* requirements described in the [input.iterators] section of the ISO C++ Standard
- the iterator does not meet the *Forward iterator* requirements described in the [forward.iterators] section of the ISO C++ Standard

Caution: If the `Body` only takes non-const lvalue reference to the `value_type`, the requirements described above are violated, and the program can be ill-formed.

Additional elements submitted into `oneapi::tbb::parallel_for_each` through the `feeder::add` are passed to the `Body` as rvalues. In this case, the corresponding execution of the `Body` is required to be well-formed.

See also:

- [parallel_for_each algorithm](#)
- [feeder class](#)

ContainerBasedSequence

[req.container_based_sequence]

A type `C` satisfies *ContainerBasedSequence* if it meets the following requirements:

ContainerBasedSequence Requirements: Pseudo-Signature, Semantics

Note: In this page `c` is an object of type (possibly `const`) `C`.

Templates that use the named requirement can impose stricter requirements on the iterator concept.

`std::begin(c)`

Returns an input iterator to the beginning of the sequence represented by `c`.

`std::end(c)`

Returns an input iterator one past the end of the sequence represented by `c`.

See also:

- [parallel_for_each algorithm](#)

- *parallel_sort* algorithm

ParallelScanBody

[req.parallel_scan]

A type *Body* satisfies *ParallelScanBody* if it meets the following requirements:

ParallelScanBody Requirements: Pseudo-Signature, Semantics

void *Body*::**operator**() (const Range &r, pre_scan_tag)

Accumulates summary for range *r*. For example, when computing a running sum of an array, the summary for a range *r* is the sum of the array elements corresponding to *r*.

void *Body*::**operator**() (const Range &r, final_scan_tag)

Computes scan result and summary for range *r*.

Body::**Body**(*Body* &b, split)

Splits *b* so that *this* and *b* can accumulate summaries separately.

void *Body*::**reverse_join**(*Body* &b)

Merges the summary accumulated by *b* into the summary accumulated by *this*, where *this* was created earlier from *b* by splitting constructor.

void *Body*::**assign**(*Body* &b)

Assigns summary of *b* to *this*.

See also:

- *parallel_scan* algorithm

ParallelScanCombine

[req.parallel_scan_combine]

A type *Combine* satisfies *ParallelScanCombine* if it meets the following requirements:

ParallelScanCombine Requirements: Pseudo-Signature, Semantics

Value *Combine*::**operator**() (const Value &left, const Value &right) const

Combines summaries *left* and *right* and returns the result *Value* type must be the same as a corresponding template parameter for the *parallel_scan* algorithm.

See also:

- *parallel_scan* algorithm

ParallelScanFunc

[req.parallel_scan_func]

A type *Scan* satisfies *ParallelScanFunc* if it meets the following requirements:

ParallelScanFunc Requirements: Pseudo-Signature, Semantics

Value *Scan*: :**operator()** (const Range &r, const Value &sum, bool is_final) const

Starting with *sum*, computes the summary *and*, for *is_final* == *true*, the scan result for range *r*. Returns the computed summary. Value type must be the same as a corresponding template parameter for the *parallel_scan* algorithm.

See also:

- *parallel_scan algorithm*

BlockedRangeValue

[req.blocked_range_value]

A type *Value* satisfies *BlockedRangeValue* if it meets the following requirements:

BlockedRangeValue Requirements: Pseudo-Signature, Semantics

Value: :**Value**(const *Value*&)

Copy constructor.

Value: :~**Value**()

Destructor.

void **operator=**(const *Value*&)

Assignment.

Note: The return type *void* in the pseudo-signature denotes that *operator=* is not required to return a value. The actual *operator=* can return a value, which will be ignored by *blocked_range* .

bool **operator<**(const *Value* &*i*, const *Value* &*j*)

Value *i* precedes value *j*.

D **operator-**(const *Value* &*i*, const *Value* &*j*)

Number of values in range [*i*, *j*).

Value **operator+**(const *Value* &*i*, D *k*)

k-th value after *i*.

D is the type of the expression *j-i*. It can be any integral type that is convertible to *size_t*. Examples that model the Value requirements are integral types, pointers, and STL random-access iterators whose difference can be implicitly converted to a *size_t*.

See also:

- *blocked_range class*
- *blocked_range2d class*
- *blocked_range3d class*

- *parallel_reduce* algorithm
- *parallel_for* algorithm

FilterBody

[req.filter_body]

A type *Body* should meet one of the following requirements depending on the filter type:

MiddleFilterBody Requirements: Pseudo-Signature, Semantics

OutputType Body : **operator()** (InputType item) const
Processes the received item and then returns it.

FirstFilterBody Requirements: Pseudo-Signature, Semantics

OutputType Body : **operator()** (oneapi::tbb::flow_control fc) const
Returns the next item from an input stream. Calls `fc.stop()` at the end of an input stream.

LastFilterBody Requirements: Pseudo-Signature, Semantics

void Body : **operator()** (InputType item) const
Processes the received item.

SingleFilterBody Requirements: Pseudo-Signature, Semantics

void Body : **operator()** (oneapi::tbb::flow_control fc) const
Processes an element from an input stream. Calls `fc.stop()` at the end of an input stream.

See also:

- *filter class*

Mutexes

Mutex

[req.mutex]

The mutexes and locks have relatively spartan interfaces that are designed for high performance. The interfaces enforce the *scoped locking pattern*, which is widely used in C++ libraries because:

- Does not require to remember to release the lock
- Releases the lock if an exception is thrown out of the mutual exclusion region protected by the lock

There are two parts of the pattern: a *mutex* object, for which construction of a *lock* object acquires a lock on the mutex and destruction of the *lock* object releases the lock. Here is an example:

```

{
    // Construction of myLock acquires lock on myMutex
    M::scoped_lock myLock( myMutex );
    // ... actions to be performed while holding the lock ...
    // Destruction of myLock releases lock on myMutex
}

```

If the actions throw an exception, the lock is automatically released as the block is exited.

```

class M {
    // Implementation specifics
    // ...

    // Represents acquisition of a mutex
    class scoped_lock {
    public:
        constexpr scoped_lock() noexcept;
        scoped_lock(M& m);
        ~scoped_lock();

        scoped_lock(const scoped_lock&) = delete;
        scoped_lock& operator=(const scoped_lock&) = delete;

        void acquire(M& m);
        bool try_acquire(M& m);
        void release();
    };
};

```

A type *M* satisfies the *Mutex* requirements if it meets the following conditions:

type **M::scoped_lock**

Corresponding scoped lock type.

M::scoped_lock()

Constructs `scoped_lock` without acquiring mutex.

M::scoped_lock(M&)

Constructs `scoped_lock` and acquire the lock on a provided mutex.

M::~~scoped_lock()

Releases a lock (if acquired).

void **M::scoped_lock::acquire(M&)**

Acquires a lock on a provided mutex.

bool **M::scoped_lock::try_acquire(M&)**

Attempts to acquire a lock on a provided mutex. Returns true if the lock is acquired, false otherwise.

void **M::scoped_lock::release()**

Releases an acquired lock.

Also, the *Mutex* type requires a set of traits to be defined:

static constexpr bool **M::is_rw_mutex**

True if mutex is a reader-writer mutex; false, otherwise.

static constexpr bool **M::is_recursive_mutex**

True if mutex is a recursive mutex; false, otherwise.

static constexpr bool M::is_fair_mutex
 True if mutex is fair; false, otherwise.

A mutex type and an M::scoped_lock type are neither copyable nor movable.

The following table summarizes the library classes that model the `Mutex` requirement and provided guarantees.

Table 1: Provided guarantees for Mutexes that model the `Mutex` requirement

	Fair	Reentrant
.		
<code>mutex</code>	No	No
<code>spin_mutex</code>	No	No
<code>speculative_spin_mutex</code>	No	No
<code>queuing_mutex</code>	Yes	No
<code>null_mutex</code>	Yes	Yes

Note: Implementation is allowed to have an opposite guarantees (positive) in case of negative statements from the table above.

See the *oneAPI Threading Building Blocks Developer Guide* for description of the mutex properties and the rationale for null mutexes.

See also:

- `mutex`
- `spin_mutex`
- `speculative_spin_mutex`
- `queuing_mutex`
- `null_mutex`

ReaderWriterMutex

[req.rw_mutex]

The `ReaderWriterMutex` requirement extends the *Mutex Requirement* to include the notion of reader-writer locks. It introduces a boolean parameter `write` that specifies whether a writer lock (`write = true`) or reader lock (`write = false`) is being requested. Multiple reader locks can be held simultaneously on a `ReaderWriterMutex` if it does not have a writer lock on it. A writer lock on a `ReaderWriterMutex` excludes all other threads from holding a lock on the mutex at the same time.

```
class RWM {
    // Implementation specifics
    // ...

    // Represents acquisition of a mutex.
    class scoped_lock {
    public:
        constexpr scoped_lock() noexcept;
        scoped_lock(RWM& m, bool write = true);
        ~scoped_lock();
    };
};
```

(continues on next page)

(continued from previous page)

```

    scoped_lock(const scoped_lock&) = delete;
    scoped_lock& operator=(const scoped_lock&) = delete;

    void acquire(RWM& m, bool write = true);
    bool try_acquire(RWM& m, bool write = true);
    void release();

    bool upgrade_to_writer();
    bool downgrade_to_reader();
};
};
};

```

A type *RWM* satisfies *ReaderWriterMutex* if it meets the following requirements. They form a superset of the *Mutex requirements*.

type **RWM::scoped_lock**

Corresponding scoped-lock type.

RWM::scoped_lock()

Constructs `scoped_lock` without acquiring any mutex.

RWM::scoped_lock(RWM&, bool write = true)

Constructs `scoped_lock` and acquires a lock on a given mutex. The lock is a writer lock if `write` is true; a reader lock otherwise.

RWM::~scoped_lock()

Releases a lock (if acquired).

void **RWM::scoped_lock::acquire(RWM&, bool write = true)**

Acquires a lock on a given mutex. The lock is a writer lock if `write` is true; it is a reader lock, otherwise.

bool **RWM::scoped_lock::try_acquire(RWM&, bool write = true)**

Attempts to acquire a lock on a given mutex. The lock is a writer lock if `write` is true; it is a reader lock, otherwise. Returns `true` if the lock is acquired, `false` otherwise.

RWM::scoped_lock::release()

Releases a lock. The effect is undefined if no lock is held.

bool **RWM::scoped_lock::upgrade_to_writer()**

Changes a reader lock to a writer lock. Returns `false` if lock was released and reacquired. Otherwise, returns `true`, including the case when the lock was already a writer lock.

bool **RWM::scoped_lock::downgrade_to_reader()**

Changes a writer lock to a reader lock. Returns `false` if lock was released and reacquired. Otherwise, returns `true`, including the case when the lock was already a reader lock.

Like the *Mutex* requirement, *ReaderWriterMutex* also requires a set of traits to be defined.

static constexpr bool **M::is_rw_mutex**

True if mutex is a reader-writer mutex; false, otherwise.

static constexpr bool **M::is_recursive_mutex**

True if mutex is a recursive mutex; false, otherwise.

static constexpr bool **M::is_fair_mutex**

True if mutex is fair; false, otherwise.

The following table summarizes the library classes that model the *ReaderWriterMutex* requirement and provided guarantees.

Table 2: Provided guarantees for Mutexes that model the ReaderWriter-Mutex requirement

.	Fair	Reentrant
<code>rw_mutex</code>	No	No
<code>spin_rw_mutex</code>	No	No
<code>speculative_spin_rw_mutex</code>	No	No
<code>queuing_rw_mutex</code>	Yes	No
<code>null_rw_mutex</code>	Yes	Yes

Note: Implementation is allowed to have an opposite guarantees (positive) in case of negative statements from the table above.

Note: For all currently provided reader-writer mutexes,

- `is_recursive_mutex` is false
- `scoped_lock::downgrade_to_reader` always returns true

However, other implementations of the ReaderWriterMutex requirement are not required to do the same.

- `queuing_rw_mutex`
- `null_rw_mutex`

Containers

HashCompare

[req.hash_compare]

HashCompare is an object which is used to calculate hash code for an object and compare two objects for equality.

The type H satisfies HashCompare if it meets the following requirements:

HashCompare Requirements: Pseudo-Signature, Semantics

`H: :H(const H&)`
Copy constructor.

`H: :~H()`
Destructor.

`std::size_t H: :hash(const KeyType &k) const`
Calculates the hash for a provided key.

ReturnType `H: :equal(const KeyType &k1, const KeyType &k2) const`
Requirements:

- The type `ReturnType` should be implicitly convertible to `bool`.

Compares `k1` and `k2` for equality.

If this function returns `true`, `H::hash(k1)` should be equal to `H::hash(k2)`.

ContainerRange

[req.container_range]

`ContainerRange` is a range that represents a concurrent container or a part of the container.

The `ContainerRange` object can be used to traverse the container in parallel algorithms like `parallel_for`.

The type `CR` satisfies the `ContainerRange` requirements if:

- The type `CR` meets the requirements of *Range requirements*.
- The type `CR` provides the following member types and functions:

type `CR::value_type`

The type of the item in the range.

type `CR::reference`

Reference type to the item in the range.

type `CR::const_reference`

Constant reference type to the item in the range.

type `CR::iterator`

Iterator type for range traversal.

type `CR::size_type`

Unsigned integer type for obtaining grain size.

type `CR::difference_type`

The type of the difference between two iterators.

iterator `CR::begin()`

Returns an iterator to the beginning of the range.

iterator `CR::end()`

Returns an iterator to the position that follows the last element in the range.

size_type `CR::grainsize()` `const`

Returns the range grain size.

Task scheduler

SuspendFunc

[req.suspend_func]

A type `Func` satisfies `SuspendFunc` if it meets the following requirements:

SuspendFunc Requirements: Pseudo-Signature, Semantics

`Func::Func(const Func&)`

Copy constructor.

void Func : : **operator**() (oneapi::tbb::task::suspend_point)
 Body that accepts the current task execution point to resume later.

See also:

- *resumable tasks*

Flow Graph

AsyncNodeBody

[req.async_node_body]

A type *Body* satisfies *AsyncNodeBody* if it meets the following requirements:

AsyncNodeBody Requirements: Pseudo-Signature, Semantics

Body : : **Body**(const *Body*&)
 Copy constructor.

Body : : ~**Body**()
 Destructor.

void *Body* : : **operator**() (const Input &v, GatewayType &gateway)

Requirements:

- The Input type must be the same as the Input template type argument of the *async_node* instance in which the *Body* object is passed during construction.
- The GatewayType type must be the same as the *gateway_type* member type of the *async_node* instance in which the *Body* object is passed during construction.

The input value *v* is submitted by the flow graph to an external activity. The *gateway interface* allows the external activity to communicate with the enclosing flow graph.

ContinueNodeBody

[req.continue_node_body]

A type *Body* satisfies *ContinueNodeBody* if it meets the following requirements:

ContinueNodeBody Requirements: Pseudo-Signature, Semantics

Body : : **Body**(const *Body*&)
 Copy constructor.

Body : : ~**Body**()
 Destructor.

Output *Body* : : **operator**() (const continue_msg &v)

Requirements: The type Output must be the same as the template type argument Output of the *continue_node* instance in which the *Body* object is passed during construction.

Performs operation and returns a value of type Output.

See also:

- *continue_node class*

- *continue_msg* class

GatewayType

[req.gateway_type]

A type *T* satisfies *GatewayType* if it meets the following requirements:

GatewayType Requirements: Pseudo-Signature, Semantics

bool *T*::**try_put**(const Output &*v*)

Requirements: The type *Output* must be the same as the template type argument *Output* of the corresponding *async_node* instance.

Broadcasts *v* to all successors of the corresponding *async_node* instance.

void *T*::**reserve_wait**()

Notifies a flow graph that work has been submitted to an external activity.

void *T*::**release_wait**()

Notifies a flow graph that work submitted to an external activity has completed.

FunctionNodeBody

[req.function_node_body]

A type *Body* satisfies *FunctionNodeBody* if it meets the following requirements:

FunctionNodeBody Requirements: Pseudo-Signature, Semantics

Body::**Body**(const *Body*&)

Copy constructor.

Body::**~Body**()

Destructor.

Output *Body*::**operator**()(const Input &*v*)

Requirements: The *Input* and *Output* types must be the same as the *Input* and *Output* template type arguments of the *function_node* instance in which the *Body* object is passed during construction.

Performs operation on *v* and returns a value of type *Output*.

JoinNodeFunctionObject

[req.join_node_function_object]

A type *Func* satisfies *JoinNodeFunctionObject* if it meets the following requirements:

JoinNodeFunctionObject Requirements: Pseudo-Signature, Semantics

Func::**Func**(const *Func*&)

Copy constructor.

Func : : ~Func()
Destructor.

Key Func : : operator() (const Input &v)

Requirements: The Key and Input types must be the same as the K and the corresponding element of the OutputTuple template arguments of the join_node instance to which the Func object is passed during construction.

Returns key to be used for hashing input messages.

InputNodeBody

[req.input_node_body]

A type *Body* satisfies *InputNodeBody* if it meets the following requirements:

InputNodeBody Requirements: Pseudo-Signature, Semantics

Body : : Body (const *Body*&)
Copy constructor.

Body : : ~Body()
Destructor.

Output Body : : operator() (oneapi::tbb::flow_control &fc)

Requirements: The type Output must be the same as the template type argument Output of the input_node instance in which the Body object is passed during construction.

Applies body to generate the next item. Call fc.stop() when new element cannot be generated. Because Output needs to be returned, Body may return any valid value of Output, to be immediately discarded.

MultifunctionNodeBody

[req.multifunction_node_body]

A type *Body* satisfies *MultifunctionNodeBody* if it meets the following requirements:

MultifunctionNodeBody Requirements: Pseudo-Signature, Semantics

Body : : Body (const *Body*&)
Copy constructor.

Body : : ~Body()
Destructor.

void Body : : operator() (const Input &v, OutputPortsType &p)

Requirements:

- The Input type must be the same as the Input template type argument of the multifunction_node instance in which the Body object is passed during construction.
- The OutputPortsType type must be the same as the output_ports_type member type of the multifunction_node instance in which the Body object is passed during construction.

Performs operation on v. May call try_put() on zero or more of the output ports. May call try_put() on any output port multiple times.

Sequencer

[req.sequencer]

A type *S* satisfies *Sequencer* if it meets the following requirements:

Sequencer Requirements: Pseudo-Signature, Semantics

S : : **S**(const *S*&)
Copy constructor.

S : : ~**S**()
Destructor.

size_t *S* : : **operator**C)(const T &v)

Requirements: The type T must be the same as the template type argument T of the `sequencer_node` instance in which the *S* object is passed during construction.

Returns the sequence number for the provided message v.

See also:

- *sequencer_node* class

9.1.5 Thread Safety

[thread_safety]

Unless otherwise stated, the thread safety rules for the library are as follows:

- Two threads can invoke a method or function concurrently on different objects, but not the same object.
- It is unsafe for two threads to invoke concurrently methods or functions on the same object.

Departures from this convention are noted in the classes descriptions. For example, the concurrent containers are more liberal. By their nature, they do permit some concurrent operations on the same container object.

9.2 oneTBB Interfaces

9.2.1 Configuration

[configuration]

This section describes the most general features of oneAPI Threading Building Blocks (oneTBB) such as namespaces, versioning, and macros.

Namespaces

[configuration.namespaces]

This section describes the oneTBB namespace conventions.

tbb Namespace

The tbb namespace contains public identifiers defined by the library that you can reference in your program.

tbb::flow Namespace

The tbb::flow namespace contains public identifiers defined by the library that you can reference in your program related to the flow graph feature. See *Flow Graph* for more information.

oneapi::tbb Namespace

The tbb namespace is a part of the top level oneapi namespace. Therefore, all API from the tbb namespace (incl. the tbb::flow namespace) are available in the oneapi::tbb namespace. The oneapi::tbb namespace can be considered as an alias for the tbb namespace:

```
namespace oneapi { namespace tbb = ::tbb; }
```

Version Information

[configuration.version_information]

oneTBB has macros, an environment variable, and a function that reveal version and runtime information.

```
// Defined in header <oneapi/tbb/version.h>

#define TBB_VERSION_MAJOR /*implementation-defined*/
#define TBB_VERSION_MINOR /*implementation-defined*/
#define TBB_VERSION_STRING /*implementation-defined*/

#define TBB_INTERFACE_VERSION_MAJOR /*implementation-defined*/
#define TBB_INTERFACE_VERSION_MINOR /*implementation-defined*/
#define TBB_INTERFACE_VERSION /*implementation-defined*/

const char* TBB_runtime_version();
int TBB_runtime_interface_version();
```

Version Macros

oneTBB defines macros related to versioning, as described below.

- TBB_VERSION_MAJOR macro defined to integral value that represents major library version.
- TBB_VERSION_MINOR macro defined to integral value that represents minor library version.
- TBB_VERSION_STRING macro defined to the string representation of the full library version.

- `TBB_INTERFACE_VERSION` macro defined to current interface version. The value is a decimal numeral of the form `xyz` where `x` is the major interface version number and `y` is the minor interface version number. This macro is increased in each release.
- `TBB_INTERFACE_VERSION_MAJOR` macro defined to `TBB_INTERFACE_VERSION/1000`, which is the major interface version number.
- `TBB_INTERFACE_VERSION_MINOR` macro defined to `TBB_INTERFACE_VERSION%1000/10`, which is the minor interface version number.

TBB_runtime_interface_version Function

Function that returns the interface version of the oneTBB library that was loaded at runtime.

The value returned by `TBB_runtime_interface_version()` may differ from the value of `TBB_INTERFACE_VERSION` obtained at compile time. This can be used to identify whether an application was compiled against a compatible version of the oneTBB headers.

In general, the run-time value `TBB_runtime_interface_version()` must be greater than or equal to the compile-time value of `TBB_INTERFACE_VERSION`. Otherwise, the application may fail to resolve all symbols at run time.

TBB_runtime_version Function

Function that returns the version string of the oneTBB library that was loaded at runtime.

The value returned by `TBB_runtime_version()` may differ from the value of `TBB_VERSION_STRING` obtained at compile time.

TBB_VERSION Environment Variable

Set the environment variable `TBB_VERSION` to 1 to cause the library to print information on `stderr`. Each line is of the form “`TBB: tag value`”, where *tag* and *value* provide additional library information below.

Caution: This output is implementation specific and may change at any time.

Enabling Debugging Features

[`configuration.debug_features`]

The following macros control certain debugging features. In general, it is useful to compile with these features on for development code, and off for production code, because the features may decrease performance. The table below summarizes the macros and their default values. A value of 1 enables the corresponding feature; a value of 0 disables the feature.

Table 3: Debugging Macros

Macro	Default Value	Feature
TBB_USE_DEBUG	<ul style="list-style-type: none"> Windows* OS: 1 if <code>_DEBUG</code> is defined, 0, otherwise. All other systems: 0. 	Default value for all other macros in this table.
TBB_USE_ASSERT	TBB_USE_DEBUG	Enable internal assertion checking. Can significantly slow down performance.
TBB_USE_PROFILING_TOOLS	TBB_USE_DEBUG	Enable full support for analysis tools.

TBB_USE_ASSERT Macro

The `TBB_USE_ASSERT` macro controls whether error checking is enabled in the header files. Define `TBB_USE_ASSERT` as 1 to enable error checking.

If an error is detected, the library prints an error message on `stderr` and calls the standard C routine `abort`. To stop a program when internal error checking detects a failure, place a breakpoint on `oneapi::tbb::assertion_failure`.

TBB_USE_PROFILING_TOOLS Macro

The `TBB_USE_PROFILING_TOOLS` macro controls support for Intel® Inspector XE, Intel® VTune™ Amplifier XE and Intel® Advisor.

Define `TBB_USE_PROFILING_TOOLS` as 1 to enable full support for these tools. Leave `TBB_USE_PROFILING_TOOLS` undefined or equal to zero to enable top performance in release builds, at the expense of turning off some support for tools.

Feature Macros

[configuration.feature_macros]

Macros in this section control optional features of the library.

TBB_USE_EXCEPTIONS macro

The `TBB_USE_EXCEPTIONS` macro controls whether the library headers use exception-handling constructs such as `try`, `catch`, and `throw`. The headers do not use these constructs when `TBB_USE_EXCEPTIONS=0`.

For the Microsoft Windows*, Linux*, and macOS* operating systems, the default value is 1 if exception handling constructs are enabled in the compiler, and 0, otherwise.

Caution: The runtime library may still throw an exception when `TBB_USE_EXCEPTIONS=0`.

TBB_USE_GLIBCXX_VERSION macro

The TBB_USE_GLIBCXX_VERSION macro can be used to specify the proper version of GNU libstdc++ if the detection fails. Define the value of the macro equal to $\text{Major} * 10000 + \text{Minor} * 100 + \text{Patch}$, where Major.Minor.Patch is the actual GCC/libstdc++ version (if unknown, it can be obtained with the 'gcc -dumpversion' command). For example, if you use libstdc++ from GCC 4.9.2, define TBB_USE_GLIBCXX_VERSION=40902.

9.2.2 Algorithms

[algorithms]

oneAPI Threading Building Blocks provides a set of generic parallel algorithms.

Parallel Functions

collaborative_call_once

[algorithms.collaborative_call_once]

Function template that executes function exactly once.

```
// Defined in header <oneapi/tbb/collaborative_call_once.h>

namespace oneapi {
    namespace tbb {

        template<typename Func, typename... Args>
        void collaborative_call_once(collaborative_once_flag& flag, Func&& func, Args&&..
→. args);

    } // namespace tbb
} // namespace oneapi
```

Requirements:

- Func type must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard.

Executes the Func object only once, even if it is called concurrently. It allows other threads blocked on the same collaborative_once_flag to join oneTBB parallel construction called within the Func object.

In case of the exception thrown from the Func object, the thread calling the Func object receives this exception. One of the threads blocked on the same collaborative_once_flag calls the Func object again.

collaborative_once_flag Class

collaborative_once_flag

[algorithms.collaborative_call_once.collaborative_once_flag]

Special class that collaborative_call_once uses to perform a call only once.

```
// Defined in header <oneapi/tbb/collaborative_call_once.h>

namespace oneapi {
    namespace tbb {

        class collaborative_once_flag {
        public:
            collaborative_once_flag();
            collaborative_once_flag(const collaborative_once_flag&) = delete;
            collaborative_once_flag& operator=(const collaborative_once_flag&) = delete;
        };
    } // namespace tbb
} // namespace oneapi
```

Member functions

collaborative_once_flag()

Constructs an collaborative_once_flag object. The initial state indicates that no function has been called.

Example

The following example shows a class in which the “Lazy initialization” pattern is implemented on the cachedProperty field.

```
#include "oneapi/tbb/collaborative_call_once.h"
#include "oneapi/tbb/parallel_reduce.h"
#include "oneapi/tbb/blocked_range.h"

extern double foo(int i);

class LazyData {
    oneapi::tbb::collaborative_once_flag flag;
    double cachedProperty;
public:
    double getProperty() {
        oneapi::tbb::collaborative_call_once(flag, [&] {
            // serial part
            double result{};

            // parallel part where threads can collaborate
            result = oneapi::tbb::parallel_reduce(oneapi::tbb::blocked_range<int>(0,
↪1000), 0.,
            [] (auto r, double val) {
```

(continues on next page)

(continued from previous page)

```

        for(int i = r.begin(); i != r.end(); ++i) {
            val += foo(i);
        }
        return val;
    },
    std::plus<double>{}
);

    // continue serial part
    cachedProperty = result;
});

return cachedProperty;
}
};

```

parallel_for

[algorithms.parallel_for]

Function template that performs parallel iteration over a range of values.

```

// Defined in header <oneapi/tbb/parallel_for.h>

namespace oneapi {
    namespace tbb {

        template<typename Index, typename Func>
        void parallel_for(Index first, Index last, const Func& f, /* see-below */
↳partitioner, task_group_context& context);
        template<typename Index, typename Func>
        void parallel_for(Index first, Index last, const Func& f, task_group_context&
↳context);
        template<typename Index, typename Func>
        void parallel_for(Index first, Index last, const Func& f, /* see-below */
↳partitioner);
        template<typename Index, typename Func>
        void parallel_for(Index first, Index last, const Func& f);

        template<typename Index, typename Func>
        void parallel_for(Index first, Index last, Index step, const Func& f, /* see-
↳below */ partitioner, task_group_context& context);
        template<typename Index, typename Func>
        void parallel_for(Index first, Index last, Index step, const Func& f, task_group_
↳context& context);
        template<typename Index, typename Func>
        void parallel_for(Index first, Index last, Index step, const Func& f, /* see-
↳below */ partitioner);
        template<typename Index, typename Func>
        void parallel_for(Index first, Index last, Index step, const Func& f);
    }
}

```

(continues on next page)

(continued from previous page)

```

    template<typename Range, typename Body>
    void parallel_for(const Range& range, const Body& body, /* see-below */
↳partitioner, task_group_context& context);
    template<typename Range, typename Body>
    void parallel_for(const Range& range, const Body& body, task_group_context&
↳context);
    template<typename Range, typename Body>
    void parallel_for(const Range& range, const Body& body, /* see-below */
↳partitioner);
    template<typename Range, typename Body>
    void parallel_for(const Range& range, const Body& body);

} // namespace tbb
} // namespace oneapi

```

A partitioner type may be one of the following entities:

- `const auto_partitioner&`
- `const simple_partitioner&`
- `const static_partitioner&`
- `affinity_partitioner&`

Requirements:

- The Range type must meet the *Range requirements*.
- The Body type must meet the *ParallelForBody requirements*.
- The Index type must meet the *ParallelForIndex requirements*.
- The Func type must meet the *ParallelForFunc requirements*.

The `oneapi::tbb::parallel_for(first, last, step, f)` overload represents parallel execution of the loop:

```
for (auto i = first; i < last; i += step) f(i);
```

The loop must not wrap around. The step value must be positive. If omitted, it is implicitly 1. There is no guarantee that the iterations run in parallel. A deadlock may occur if a lesser iteration waits for a greater iteration. The partitioning strategy is `auto_partitioner` when the parameter is not specified.

The `parallel_for(range, body, partitioner)` overload provides a more general form of parallel iteration. It represents parallel execution of `body` over each value in `range`. The optional `partitioner` parameter specifies a partitioning strategy.

`parallel_for` recursively splits the range into subranges to the point such that `is_divisible()` is false for each subrange, and makes copies of the body for each of these subranges. For each such body/subrange pair, it invokes `Body::operator()`.

Some of the copies of the range and body may be destroyed after `parallel_for` returns. This late destruction is not an issue in typical usage, but is something to be aware of when looking at execution traces or writing range or body objects with complex side effects.

`parallel_for` may execute iterations in non-deterministic order. Do not rely on any particular execution order for correctness. However, for efficiency, do expect `parallel_for` to tend towards operating on consecutive runs of values.

In case of serial execution, `parallel_for` performs iterations from left to right in the following sense.

All overloads can accept a *task_group_context* object so that the algorithm's tasks are executed in this context. By default, the algorithm is executed in a bound context of its own.

Complexity

If the range and body take $O(I)$ space, and the range splits into nearly equal pieces, the space complexity is $O(P \log(N))$, where N is the size of the range and P is the number of threads.

- *Partitioners*

parallel_reduce

[algorithms.parallel_reduce]

Function template that computes reduction over a range.

```
// Defined in header <oneapi/tbb/parallel_reduce.h>

namespace oneapi {
    namespace tbb {

        template<typename Range, typename Value, typename Func, typename Reduction>
        Value parallel_reduce(const Range& range, const Value& identity, const Func&
        ↪func, const Reduction& reduction, /* see-below */ partitioner, task_group_context&
        ↪context);

        template<typename Range, typename Value, typename Func, typename Reduction>
        Value parallel_reduce(const Range& range, const Value& identity, const Func&
        ↪func, const Reduction& reduction, /* see-below */ partitioner);

        template<typename Range, typename Value, typename Func, typename Reduction>
        Value parallel_reduce(const Range& range, const Value& identity, const Func&
        ↪func, const Reduction& reduction, task_group_context& context);

        template<typename Range, typename Value, typename Func, typename Reduction>
        Value parallel_reduce(const Range& range, const Value& identity, const Func&
        ↪func, const Reduction& reduction);

        template<typename Range, typename Body>
        void parallel_reduce(const Range& range, Body& body, /* see-below */ partitioner,
        ↪ task_group_context& context);

        template<typename Range, typename Body>
        void parallel_reduce(const Range& range, Body& body, /* see-below */
        ↪partitioner);

        template<typename Range, typename Body>
        void parallel_reduce(const Range& range, Body& body, task_group_context&
        ↪context);

        template<typename Range, typename Body>
        void parallel_reduce(const Range& range, Body& body);

    } // namespace tbb
} // namespace oneapi
```

A partitioner type may be one of the following entities:

- `const auto_partitioner&`
- `const simple_partitioner&`

- `const static_partitioner&`
- `affinity_partitioner&`

Requirements:

- The Range type must meet the *Range requirements*.
- The Body type must meet the *ParallelReduceBody requirements*.
- The Func type must meet the *ParallelReduceFunc requirements*.
- The Reduction types must meet *ParallelReduceReduction requirements*.

The function template `parallel_reduce` has two forms: The functional form is designed to be easy to use in conjunction with lambda expressions. The imperative form is designed to minimize copying of data.

The functional form `parallel_reduce(range, identity, func, reduction)` performs a parallel reduction by applying `func` to subranges in `range` and reducing the results with the binary operator `reduction`. It returns the result of the reduction. The `identity` parameter specifies the left identity element for `func`'s `operator()`. Parameters `func` and `reduction` can be lambda expressions.

The imperative form `parallel_reduce(range, body)` performs parallel reduction of `body` over each value in `range`.

A `parallel_reduce` recursively splits the range into subranges to the point such that `is_divisible()` is false for each subrange. A `parallel_reduce` uses the splitting constructor to make one or more copies of the body for each thread. It may copy a body while the body's `operator()` or method `join` runs concurrently. You are responsible for ensuring the safety of such concurrency. In typical usage, the safety requires no extra effort.

`parallel_reduce` may invoke the splitting constructor for the body. For each such split of the body, it invokes the `join` method to merge the results from the bodies. Define `join` to update this to represent the accumulated result for this and rhs. The reduction operation should be associative, but does not have to be commutative. For a noncommutative operation `op`, `left.join(right)` should update `left` to be the result of `left op right`.

A body is split only if the range is split, but the converse is not necessarily to be so. The user must neither rely on a particular choice of body splitting nor on the subranges processed by a given body object being consecutive. `parallel_reduce` makes the choice of body splitting nondeterministically.

When executed serially `parallel_reduce` run sequentially from left to right in the same sense as for `parallel_for`. Sequential execution never invokes the splitting constructor or method `join`.

All overloads can accept a `task_group_context` object so that the algorithm's tasks are executed in this context. By default, the algorithm is executed in a bound context of its own.

Complexity

If the range and body take $O(1)$ space, and the range splits into nearly equal pieces, the space complexity is $O(P \times \log(N))$, where N is the size of the range and P is the number of threads.

Example (Imperative Form)

The following code sums the values in an array.

```
#include "oneapi/tbb/parallel_reduce.h"
#include "oneapi/tbb/blocked_range.h"

using namespace oneapi::tbb;

struct Sum {
    float value;
```

(continues on next page)

(continued from previous page)

```

Sum() : value(0) {}
Sum( Sum& s, split ) {value = 0;}
void operator()( const blocked_range<float*>& r ) {
    float temp = value;
    for( float* a=r.begin(); a!=r.end(); ++a ) {
        temp += *a;
    }
    value = temp;
}
void join( Sum& rhs ) {value += rhs.value;}
};

float ParallelSum( float array[], size_t n ) {
    Sum total;
    parallel_reduce( blocked_range<float*>( array, array+n ), total );
    return total.value;
}

```

The example generalizes to reduction for any associative operation *op* as follows:

- Replace occurrences of 0 with the identity element for *op*
- Replace occurrences of += with *op*= or its logical equivalent.
- Change the name Sum to something more appropriate for *op*.

The operation may be noncommutative. For example, *op* could be matrix multiplication.

Example with Lambda Expressions

The following is similar to the previous example, but written using lambda expressions and the functional form of `parallel_reduce`.

```

#include "oneapi/tbb/parallel_reduce.h"
#include "oneapi/tbb/blocked_range.h"

using namespace oneapi::tbb;

float ParallelSum( float array[], size_t n ) {
    return parallel_reduce(
        blocked_range<float*>( array, array+n ),
        0.f,
        [] (const blocked_range<float*>& r, float init) -> float {
            for( float* a=r.begin(); a!=r.end(); ++a )
                init += *a;
            return init;
        },
        [] ( float x, float y ) -> float {
            return x+y;
        }
    );
}

```

- *Partitioners*

parallel_deterministic_reduce

[algorithms.parallel_deterministic_reduce]

Function template that computes reduction over a range, with deterministic split/join behavior.

```
// Defined in header <oneapi/tbb/parallel_reduce.h>

namespace oneapi {
    namespace tbb {

        template<typename Range, typename Value, typename Func, typename Reduction>
        Value parallel_deterministic_reduce( const Range& range, const Value& identity,
        ↪const Func& func, const Reduction& reduction, /* see-below */ partitioner, task_group_
        ↪context& context);
        template<typename Range, typename Value, typename Func, typename Reduction>
        Value parallel_deterministic_reduce( const Range& range, const Value& identity,
        ↪const Func& func, const Reduction& reduction, /* see-below */ partitioner);
        template<typename Range, typename Value, typename Func, typename Reduction>
        Value parallel_deterministic_reduce( const Range& range, const Value& identity,
        ↪const Func& func, const Reduction& reduction, task_group_context& context);
        template<typename Range, typename Value, typename Func, typename Reduction>
        Value parallel_deterministic_reduce( const Range& range, const Value& identity,
        ↪const Func& func, const Reduction& reduction);

        template<typename Range, typename Body>
        void parallel_deterministic_reduce( const Range& range, Body& body, /* see-below
        ↪*/ partitioner, task_group_context& context);
        template<typename Range, typename Body>
        void parallel_deterministic_reduce( const Range& range, Body& body, /* see-below
        ↪*/ partitioner);
        template<typename Range, typename Body>
        void parallel_deterministic_reduce( const Range& range, Body& body, task_group_
        ↪context& context);
        template<typename Range, typename Body>
        void parallel_deterministic_reduce( const Range& range, Body& body);

    } // namespace tbb
} // namespace oneapi
```

A partitioner type may be one of the following entities:

- `const simple_partitioner&`
- `const static_partitioner&`

The function template `parallel_deterministic_reduce` is very similar to the `parallel_reduce` template. It also has the functional and imperative forms and has *similar requirements*.

Unlike `parallel_reduce`, `parallel_deterministic_reduce` has deterministic behavior with regard to splits of both `Body` and `Range` and joins of the bodies. For the functional form, `Func` is applied to a deterministic set of `Ranges`, and `Reduction` merges partial results in a deterministic order. To achieve that, `parallel_deterministic_reduce` uses a `simple_partitioner` or a `static_partitioner` only because other partitioners react to random work stealing behavior.

Caution: Since `simple_partitioner` does not automatically coarsen ranges, make sure to specify an appropriate grain size. See *Partitioners section* for more information.

`parallel_deterministic_reduce` always invokes the `Body` splitting constructor for each range split.

As a result, `parallel_deterministic_reduce` recursively splits a range until it is no longer divisible, and creates a new body (by calling the `Body` splitting constructor) for each new subrange. Like `parallel_reduce`, for each body split the method `join` is invoked in order to merge the results from the bodies.

Therefore, for given arguments, `parallel_deterministic_reduce` executes the same set of split and join operations no matter how many threads participate in execution and how tasks are mapped to the threads. If the user-provided functions are also deterministic (that is, different runs with the same input result in the same output), multiple calls to `parallel_deterministic_reduce` produce the same result. Note however that the result might differ from that obtained with an equivalent sequential (linear) algorithm.

Complexity

If the range and body take $O(I)$ space, and the range splits into nearly equal pieces, the space complexity is $O(P \log(N))$, where N is the size of the range and P is the number of threads.

- [parallel_reduce](#)
- [Partitioners](#)

parallel_scan

[algorithms.parallel_scan]

Function template that computes a parallel prefix.

```
// Defined in header <oneapi/tbb/parallel_scan.h>

template<typename Range, typename Body>
void parallel_scan( const Range& range, Body& body );
template<typename Range, typename Body>
void parallel_scan( const Range& range, Body& body, /* see-below */ partitioner );

template<typename Range, typename Value, typename Scan, typename Combine>
Value parallel_scan( const Range& range, const Value& identity, const Scan& scan, const_
↳Combine& combine );
template<typename Range, typename Value, typename Scan, typename Combine>
Value parallel_scan( const Range& range, const Value& identity, const Scan& scan, const_
↳Combine& combine, /* see-below */ partitioner );
```

A partitioner type may be one of the following entities:

- `const auto_partitioner&`
- `const simple_partitioner&`

Requirements:

- The `Range` type must meet the *Range requirement*.
- The `Body` type must meet the *ParallelScanBody requirements*.
- The `Scan` type must meet the *ParallelScanFunc requirements*.

- The Combine type must meet the *ParallelScanCombine requirements*.

The function template `parallel_scan` computes a parallel prefix, also known as a parallel scan. This computation is an advanced concept in parallel computing that is sometimes useful in scenarios that appear to have inherently serial dependences.

A mathematical definition of the parallel prefix is as follows. Let \times be an associative operation with left-identity element id_\times . The parallel prefix of \times over a sequence z_0, z_1, \dots, z_{n-1} is a sequence $y_0, y_1, y_2, \dots, y_{n-1}$ where:

- $y_0 = \text{id}_\times \times z_0$
- $y_i = y_{i-1} \times z_i$

For example, if \times is addition, the parallel prefix corresponds to a running sum. A serial implementation of a parallel prefix is:

```
T temp = id;
for( int i=1; i<=n; ++i ) {
    temp = temp + z[i];
    y[i] = temp;
}
```

Parallel prefix performs this in parallel by reassociating the application of \times (+ in example) and using two passes. It may invoke \times up to twice as many times as the serial prefix algorithm. Even though it does more work, given the right grain size the parallel algorithm can outperform the serial one because it distributes the work across multiple hardware threads.

The function template `parallel_scan` has two forms. The imperative form `parallel_scan(range, body)` implements parallel prefix generically.

A summary (refer to *ParallelScanBody requirements*) contains enough information such that for two consecutive sub-ranges r and s :

- If r has no preceding subrange, the scan result for s can be computed from knowing s and the summary for r .
- A summary of r concatenated with s can be computed from the summaries of r and s .

The functional form `parallel_scan(range, identity, scan, combine)` is designed to use with functors and lambda expressions, hiding some complexities of the imperative form. It uses the same `scan` functor in both passes, differentiating them via a boolean parameter, combines summaries with `combine` functor, and returns the summary computed over the whole `range`. The `identity` argument is the left identity element for `Scan::operator()`.

pre_scan and final_scan Classes

pre_scan_tag and final_scan_tag

[algorithms.parallel_scan.scan_tags]

Types that distinguish the phases of `parallel_scan`.

Types `pre_scan_tag` and `final_scan_tag` are dummy types used in conjunction with `parallel_scan`. See the example in the *parallel_scan* section for demonstration of how they are used in the signature of `operator()`.

```
// Defined in header <oneapi/tbb/parallel_scan.h>

namespace oneapi {
    namespace tbb {
```

(continues on next page)

(continued from previous page)

```

struct pre_scan_tag {
    static bool is_final_scan();
    operator bool();
};

struct final_scan_tag {
    static bool is_final_scan();
    operator bool();
};

} // namespace tbb
} // namespace oneapi

```

Member functions

`bool is_final_scan()`
true for a `final_scan_tag`, false, otherwise.

`operator bool()`
true for a `final_scan_tag`, false, otherwise.

The `parallel_scan` template makes an effort to avoid prescanning where possible. When executed serially, `parallel_scan` processes the subranges without any pre-scans by processing the subranges from left to right using final scans. That is why final scans must compute a summary as well as the final scan result. The summary might be needed to process the next subrange if no other thread has pre-scanned it yet.

Example (Imperative Form)

The following code demonstrates how `Body` could be implemented for `parallel_scan` to compute the same result as in the earlier sequential example.

```

class Body {
    T sum;
    T* const y;
    const T* const z;
public:
    Body( T y_[], const T z_[] ) : sum(id), z(z_), y(y_) {}
    T get_sum() const { return sum; }

    template<typename Tag>
    void operator()( const oneapi::tbb::blocked_range<int>& r, Tag ) {
        T temp = sum;
        for( int i=r.begin(); i<r.end(); ++i ) {
            temp = temp + z[i];
            if( Tag::is_final_scan() )
                y[i] = temp;
        }
        sum = temp;
    }
    Body( Body& b, oneapi::tbb::split ) : z(b.z), y(b.y), sum(id) {}
    void reverse_join( Body& a ) { sum = a.sum + sum; }
}

```

(continues on next page)

(continued from previous page)

```

    void assign( Body& b ) { sum = b.sum; }
};

T DoParallelScan( T y[], const T z[], int n ) {
    Body body(y,z);
    oneapi::tbb::parallel_scan( oneapi::tbb::blocked_range<int>(0,n), body );
    return body.get_sum();
}

```

The definition of operator() demonstrates typical patterns when using parallel_scan.

- A single template defines both versions. Doing so is not required, but usually saves coding effort, because two versions are usually similar. The library defines the static method is_final_scan to enable differentiation between the versions.
- The prescan variant computes the \times reduction, but does not update y. The prescan is used by parallel_scan to generate look-ahead partial reductions.
- The final scan variant computes the \times reduction and updates y.

The reverse_join operation is similar to the join operation used by parallel_reduce, except that the arguments are reversed. That is, this is the *right* argument of \times . The template function parallel_scan decides if and when to generate parallel work. Thus, it is crucial that \times is associative and that the methods of Body faithfully represent it. Operations such as floating-point addition, which are somewhat associative, can be used with the understanding that the results may be rounded differently depending on the association used by parallel_scan. The reassociation may differ between runs even on the same machine. However, when executed serially, parallel_scan associates identically to the serial form shown at the beginning of this section.

If you change the example to use a simple_partitioner, be sure to provide a grain size. The code below shows how to do this for the grain size of 1000:

```
parallel_scan( blocked_range<int>(0,n,1000), total, simple_partitioner() );
```

Example with Lambda Expressions

The following is analogous to the previous example, but written using lambda expressions and the functional form of parallel_scan:

```

T DoParallelScan( T y[], const T z[], int n ) {
    return oneapi::tbb::parallel_scan(
        oneapi::tbb::blocked_range<int>(0,n),
        id,
        [](const oneapi::tbb::blocked_range<int>& r, T sum, bool is_final_scan)->T {
            T temp = sum;
            for( int i=r.begin(); i<r.end(); ++i ) {
                temp = temp + z[i];
                if( is_final_scan )
                    y[i] = temp;
            }
            return temp;
        },
        []( T left, T right ) {
            return left + right;
        }
    );
}

```

(continues on next page)

(continued from previous page)

```

    }
);
}

```

See also:

- *blocked_range class*
- *parallel_reduce algorithm*

parallel_for_each

[algorithms.parallel_for_each]

Function template that processes work items in parallel.

```

// Defined in header <oneapi/tbb/parallel_for_each.h>

namespace oneapi {
    namespace tbb {

        template<typename InputIterator, typename Body>
        void parallel_for_each( InputIterator first, InputIterator last, Body body );
        template<typename InputIterator, typename Body>
        void parallel_for_each( InputIterator first, InputIterator last, Body body, task_
↪group_context& context );

        template<typename Container, typename Body>
        void parallel_for_each( Container& c, Body body );
        template<typename Container, typename Body>
        void parallel_for_each( Container& c, Body body, task_group_context& context );

        template<typename Container, typename Body>
        void parallel_for_each( const Container& c, Body body );
        template<typename Container, typename Body>
        void parallel_for_each( const Container& c, Body body, task_group_context&
↪context );

    } // namespace tbb
} // namespace oneapi

```

Requirements:

- The Body type must meet the *ParallelForEachBody requirements*.
- The InputIterator type must meet the *Input Iterator* requirements from the [input.iterators] ISO C++ Standard section.
- The Container type must meet the *ContainerBasedSequence requirements*.

The parallel_for_each template has two forms.

The sequence form parallel_for_each(first, last, body) applies a function object body over a sequence [first, last). Items may be processed in parallel.

The container form `parallel_for_each(c, body)` is equivalent to `parallel_for_each(std::begin(c), std::end(c), body)`.

All overloads can accept a *task_group_context* object so that the algorithm's tasks are executed in this context. By default, the algorithm is executed in a bound context of its own.

feeder Class

Additional work items can be added by `body` if it has a second argument of type `feeder`. The function terminates when `body(x)` returns for all items `x` that were in the input sequence or added by method `feeder::add`.

feeder

[algorithms.parallel_for_each.feeder]

Inlet into which additional work items for a `parallel_for_each` can be fed.

```
// Defined in header <oneapi/tbb/parallel_for_each.h>

namespace oneapi {
    namespace tbb {

        template<typename Item>
        class feeder {
        public:
            void add( const Item& item );
            void add( Item&& item );
        };

    } // namespace tbb
} //namespace oneapi
```

Member functions

void **add**(const Item &item)
Adds item to a collection of work items to be processed.

void **add**(Item &&item)
Same as the above but uses the move constructor of `Item`, if available.

Caution: Must be called from a `Body::operator()` created by the `parallel_for_each` function. Otherwise, the termination semantics of method `operator()` are undefined.

Example

The following code sketches a body with the two-argument form of `operator()`.

```

struct MyBody {
    void operator()(item_t item, parallel_do_feeder<item_t>& feeder ) {
        for each new piece of work implied by item do {
            item_t new_item = initializer;
            feeder.add(new_item);
        }
    }
};

```

parallel_invoke

[algorithms.parallel_invoke]

Function template that evaluates several functions in parallel.

```

// Defined in header <oneapi/tbb/parallel_invoke.h>

namespace oneapi {
    namespace tbb {

        template<typename... Functions>
        void parallel_invoke(Functions&&... fs);

    } // namespace tbb
} // namespace oneapi

```

Requirements:

- All members of `Functions` parameter pack must meet *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard.
- Last member of `Functions` parameter pack may be a `task_group_context&` type.

Evaluates each member passed to `parallel_invoke` possibly in parallel. Return values are ignored.

The algorithm can accept a *task_group_context* object so that the algorithm's tasks are executed in this context. By default, the algorithm is executed in a bound context of its own.

Example

The following example evaluates `f()`, `g()`, `h()`, and `bar(1)` in parallel.

```

#include "oneapi/tbb/parallel_invoke.h"

extern void f();
extern void bar(int);

class MyFunctor {
    int arg;

```

(continues on next page)

(continued from previous page)

```

public:
    MyFunctor(int a) : arg(a) {}
    void operator()() const { bar(arg); }
};

void RunFunctionsInParallel() {
    MyFunctor g(2);
    MyFunctor h(3);

    oneapi::tbb::parallel_invoke(f, g, h, []{bar(1);});
}

```

parallel_pipeline

[algorithms.parallel_pipeline]

Strongly-typed interface for pipelined execution.

```

// Defined in header <oneapi/tbb/parallel_pipeline.h>

namespace oneapi {
    namespace tbb {

        void parallel_pipeline( size_t max_number_of_live_tokens, const filter<void,void>
        →& filter_chain );
        void parallel_pipeline( size_t max_number_of_live_tokens, const filter<void,void>
        →& filter_chain, task_group_context& context );

    } // namespace tbb
} // namespace oneapi

```

A `parallel_pipeline` algorithm represents pipelined application of a series of filters to a stream of items. Each filter operates in a particular mode: parallel, serial in-order, or serial out-of-order.

To build and run a pipeline from functors $g_0, g_1, g_2, \dots, g_n$, write:

```

parallel_pipeline( max_number_of_live_tokens,
    make_filter<void,I1>(mode0,g0) &
    make_filter<I1,I2>(mode1,g1) &
    make_filter<I2,I3>(mode2,g2) &
    ...
    make_filter<In,void>(moden,gn) );

```

In general, the g_i functor should define its `operator()` to map objects of type I_i to objects of type I_{i+1} . Functor g_0 is a special case, because it notifies the pipeline when the end of an input stream is reached. Functor g_0 must be defined such that for a *flow_control* object fc , the expression $g_0(fc)$ either returns the next value in the input stream, or invokes $fc.stop()$ if the end of the input stream is reached and returns a dummy value.

Each *filter* should be specified by two template arguments. These arguments define filters input and output types. The first and last filters are special cases. Input type of the first filter must be *void*, output type of the last filter must be *void* too.

Before passing to `parallel_pipeline`, concatenate all filters to `one(filter<void, void>)` with `filter::operator&()`. The operator requires that the second template argument of its left operand matches the first template argument of its

second operand.

The number of items processed in parallel depends on the structure of the pipeline and number of available threads. *max_number_of_live_tokens* sets the threshold for concurrently processed items.

If the *context* argument is specified, pipeline's tasks are executed in this context. By default, the algorithm is executed in a bound context of its own.

Example

The following example uses `parallel_pipeline` to compute the root-mean-square of a sequence defined by [*first* , *last*).

```
float RootMeanSquare( float* first, float* last ) {
    float sum=0;
    parallel_pipeline( /*max_number_of_live_token=*/16,
        make_filter<void, float*>(
            filter::serial,
            [&](flow_control& fc)-> float*{
                if( first<last ) {
                    return first++;
                } else {
                    fc.stop();
                    return nullptr;
                }
            }
        ) &
        make_filter<float*, float>(
            filter::parallel,
            [](float* p){return (*p)*(*p);}
        ) &
        make_filter<float, void>(
            filter::serial,
            [&](float x) {sum+=x;}
        )
    );
    return sqrt(sum);
}
```

filter Class Template

filter

[algorithms.parallel_pipeline.filter]

A filter class template represents a strongly-typed filter in a `parallel_pipeline` algorithm, with its template parameters specifying the filter input and output types. A filter can be constructed from a functor or by composing two filter objects with `operator&()`. The same filter object can be reused in multiple `&` expressions.

The filter class should only be used in conjunction with `parallel_pipeline` functions.

```
// Defined in header <oneapi/tbb/parallel_pipeline.h>
```

(continues on next page)

(continued from previous page)

```

namespace oneapi {
    namespace tbb {

        template<typename InputType, typename OutputType>
        class filter {
        public:
            filter() = default;
            filter( const filter& rhs ) = default;
            filter( filter&& rhs ) = default;
            void operator=(const filter& rhs) = default;
            void operator=( filter&& rhs ) = default;

            template<typename Body>
            filter( filter_mode mode, const Body& body );

            filter& operator&=( const filter<OutputType,OutputType>& right );

            void clear();
        }

        template<typename T, typename U, typename Body>
        filter<T,U> make_filter( filter::mode mode, const Body& f );
        template<typename T, typename V, typename U>
        filter<T,U> operator&( const filter<T,V>& left, const filter<V,U>& right );

    } // namespace tbb
} // namespace oneapi

```

Requirements:

- If *InputType* is void, a *Body* type must meet the *StartFilterBody requirements*.
- If *OutputType* is void, a *Body* type must meet the *OutputFilterBody requirements*.
- If *InputType* and *OutputType* are not void, a *Body* type must meet the *MiddleFilterBody requirements*.
- If *InputType* and *OutputType* are void, a *Body* type must meet the *SingleFilterBody requirements*.

filter_mode Enumeration

filter_mode

[algorithms.parallel_pipeline.filter_mode]

A *filter_mode* enumeration represents an execution mode of a *filter* in a *parallel_pipeline* algorithm.

Its enumerated values and their meanings are as follows:

- A *parallel* filter can process multiple items in parallel and without a particular order.
- A *serial_out_of_order* filter processes items one at a time and without a particular order.
- A *serial_in_order* filter processes items one at a time. The order in which items are processed is implicitly set by the first *serial_in_order* filter and respected by all other such filters in the pipeline.

```
// Defined in header <oneapi/tbb/parallel_pipeline.h>

namespace oneapi {
    namespace tbb {

        enum class filter_mode {
            parallel = /*implementation-defined*/,
            serial_in_order = /*implementation-defined*/,
            serial_out_of_order = /*implementation-defined*/
        };

    } // namespace tbb
} // namespace oneapi
```

Member functions

filter()

Constructs an undefined filter.

Caution: The effect of using an undefined filter by operator&() or parallel_pipeline is undefined.

template<typename **Body**>

filter(filter_mode mode, const *Body* &body)

Constructs a *filter* that uses a copy of a provided body to map an input value of type *InputType* to an output value of type *OutputType*, and that operates in the specified mode.

void **clear**()

Sets *this to an undefined filter.

Non-member functions

template<typename **T**, typename **U**, typename **Func**>

filter<**T**, **U**> **make_filter**(*filter*::mode mode, const *Func* &f)

Returns *filter*<**T**, **U**>(mode, f).

template<typename **T**, typename **V**, typename **U**>

filter<**T**, **U**> **operator&**(const *filter*<**T**, **V**> &left, const *filter*<**V**, **U**> &right)

Returns a *filter* representing the composition of filters *left* and *right*. The composition behaves as if the output value of *left* becomes the input value of *right*.

Deduction Guides

```
template<typename Body>
filter(filter_mode, Body) -> filter<filter_input<Body>, filter_output<Body>>;
```

Where:

- `filter_input<Body>` is an alias to the `Body::operator()` input parameter type. If `Body::operator()` input parameter type is `flow_control` then `filter_input<Body>` is `void`.
- `filter_output<Body>` is an alias to the `Body::operator()` return type.

flow_control Class

flow_control

[algorithms.parallel_pipeline.flow_control]

Enables the first filter in a composite filter to indicate when the end of input stream is reached.

Template function `parallel_pipeline` passes a `flow_control` object to the functor of the first filter. When the functor reaches the end of its input stream, it should invoke `fc.stop()` and return a dummy value that will not be passed to the next filter.

```
// Defined in header <oneapi/tbb/parallel_pipeline.h>

namespace oneapi {
    namespace tbb {

        class flow_control {
        public:
            void stop();
        };

    } // namespace tbb
} namespace oneapi
```

Member functions

void **stop()**

Indicates that first filter of the pipeline reaches the end of its output.

See also:

- *FilterBody requirements*
- *filter class*

See also:

- *task_group_context*

parallel_sort

[algorithms.parallel_sort]

Function template that sorts a sequence.

```
// Defined in header <oneapi/tbb/parallel_sort.h>

namespace oneapi {
    namespace tbb {

        template<typename RandomAccessIterator>
        void parallel_sort( RandomAccessIterator begin, RandomAccessIterator end );
        template<typename RandomAccessIterator, typename Compare>
        void parallel_sort( RandomAccessIterator begin, RandomAccessIterator end, const_
↪ Compare& comp );

        template<typename Container>
        void parallel_sort( Container&& c );
        template<typename Container>
        void parallel_sort( Container&& c, const Compare& comp );

    } // namespace tbb
} // namespace oneapi
```

Requirements:

- The `RandomAccessIterator` type must meet the *Random Access Iterators* requirements from [random.access.iterators] and *ValueSwappable* requirements from the [swappable.requirements] ISO C++ Standard section.
- The `Compare` type must meet the *Compare* type requirements from the [alg.sorting] ISO C++ Standard section.
- The `Container` type must meet the *ContainerBasedSequence requirements* which iterators must meet the *Random Access Iterators* requirements from [random.access.iterators] and *Swappable* requirements from the [swappable.requirements] ISO C++ Standard section.
- The type of dereferenced `RandomAccessIterator` or dereferenced `Container` iterator must meet the *Move-Assignable* requirements from [moveassignable] section of ISO C++ Standard and the *MoveConstructible* requirements from [moveconstructible] section of ISO C++ Standard.

Sorts a sequence or a container. The sort is neither stable nor deterministic: relative ordering of elements with equal keys is not preserved and not guaranteed to repeat if the same sequence is sorted again.

A call `parallel_sort(begin, end, comp)` sorts the sequence $[begin, end)$ using the argument `comp` to determine relative orderings. If `comp(x, y)` returns `true`, x appears before y in the sorted sequence.

A call `parallel_sort(begin, end)` is equivalent to `parallel_sort(begin, end, comp)`, where `comp` uses `operator<` to determine relative orderings.

A call `parallel_sort(c, comp)` is equivalent to `parallel_sort(std::begin(c), std::end(c), comp)`.

A call `parallel_sort(c)` is equivalent to `parallel_sort(c, comp)`, where `comp` uses `operator<` to determine relative orderings.

Complexity

`parallel_sort` is a comparison sort with an average time complexity of $O(N \times \log(N))$, where N is the number of elements in the sequence. `parallel_sort` may be executed concurrently to improve execution time.

Blocked Ranges

Types that meet the *Range requirements*.

blocked_range

[algorithms.blocked_range]

Class template for a recursively divisible half-open interval.

A `blocked_range` represents a half-open range $[i,*j*)$ that can be recursively split.

A `blocked_range` meets the *Range requirements*.

A `blocked_range` specifies a *grain size* of type `size_t`.

A `blocked_range` is splittable into two subranges if the size of the range exceeds its grain size. The ideal grain size depends on the context of the `blocked_range`, which is typically passed as the range argument to the loop templates `parallel_for`, `parallel_reduce`, or `parallel_scan`.

```
// Defined in header <oneapi/tbb/blocked_range.h>

namespace oneapi {
    namespace tbb {

        template<typename Value>
        class blocked_range {
        public:
            // types
            using size_type = size_t;
            using const_iterator = Value;

            // constructors
            blocked_range( Value begin, Value end, size_type grainsize=1 );
            blocked_range( blocked_range& r, split );
            blocked_range( blocked_range& r, proportional_split& proportion );

            // capacity
            size_type size() const;
            bool empty() const;

            // access
            size_type grainsize() const;
            bool is_divisible() const;

            // iterators
            const_iterator begin() const;
            const_iterator end() const;
        };

    } // namespace tbb
} // namespace oneapi
```

Requirements:

- The Value type must meet the *BlockedRangeValue requirements*.

Member functions

type **size_type**

The type for measuring the size of a `blocked_range`. The type is always a `size_t`.

type **const_iterator**

The type of a value in the range. Despite its name, the `const_iterator` type is not necessarily an STL iterator; it merely needs to meet the *BlockedRangeValue requirements*. However, it is convenient to call it `const_iterator` so that if it is a `const_iterator`, the `blocked_range` behaves like a read-only STL container.

blocked_range(Value begin, Value end, *size_type* grainsize = 1)

Requirements: The parameter `grainsize` must be positive. The debug version of the library raises an assertion failure if this requirement is not met.

Effects: Constructs a `blocked_range` representing the half-open interval `[begin, end)` with the given `grainsize`.

Example: The statement `"blocked_range<int> r(5, 14, 2);"` constructs a range of `int` that contains the values 5 through 13 inclusive, with the grain size of 2. Afterwards, `r.begin()==5` and `r.end()==14`.

blocked_range(*blocked_range* &range, split)

Basic splitting constructor.

Requirements: `is_divisible()` is true.

Effects: Partitions `range` into two subranges. The newly constructed `blocked_range` is approximately the second half of the original `range`, and `range` is updated to be the remainder. Each subrange has the same `grainsize` as the original `range`.

Example: Let `r` be a `blocked_range` that represents a half-open interval `[i, j)` with a grain size `g`. Running the statement `blocked_range<int> s(r, split);` subsequently causes `r` to represent `[i, i+(j-i)/2)` and `s` to represent `[i+(j-i)/2, j)`, both with grain size `g`.

blocked_range(*blocked_range* &range, *proportional_split* proportion)

Proportional splitting constructor.

Requirements: `is_divisible()` is true.

Effects: Partitions `range` into two subranges such that the ratio of their sizes is close to the ratio of `proportion.left()` to `proportion.right()`. The newly constructed `blocked_range` is the subrange at the right, and `range` is updated to be the subrange at the left.

Example: Let `r` be a `blocked_range` that represents a half-open interval `[i, j)` with a grain size `g`. Running the statement `blocked_range<int> s(r, proportional_split(2, 3));` subsequently causes `r` to represent `[i, i+2*(j-i)/(2+3))` and `s` to represent `[i+2*(j-i)/(2+3), j)`, both with grain size `g`.

size_type **size**() const

Requirements: `end()<begin()` is false.

Effects: Determines size of range.

Returns: `end()-begin()`.

bool **empty**() const

Effects: Determines if range is empty.

Returns: `!(begin()<end())`

size_type **grainsize**() const

Returns: Grain size of range.

bool **is_divisible**() const

Requirements: `end()<begin()` is false.

Effects: Determines if the range can be split into subranges.

Returns: True if `size()>grainsize()`; false, otherwise.

const_iterator **begin**() const

Returns: Inclusive lower bound of the range.

const_iterator **end**() const

Returns: Exclusive upper bound of the range.

- *parallel_reduce*
- *parallel_for*
- *parallel_scan*

blocked_range2d

[algorithms.blocked_range2d]

Class template that represents a recursively divisible two-dimensional half-open interval.

A `blocked_range2d` represents a half-open two-dimensional range $[i_0, j_0) \times [i_1, j_1)$. Each axis of the range has its own splitting threshold. A `blocked_range2d` is divisible if either axis is divisible.

A `blocked_range2d` meets the *Range requirements*.

```
// Defined in header <oneapi/tbb/blocked_range2d.h>

namespace oneapi {
    namespace tbb {

        template<typename RowValue, typename ColValue=RowValue>
        class blocked_range2d {
        public:
            // Types
            using row_range_type = blocked_range<RowValue>;
            using col_range_type = blocked_range<ColValue>;

            // Constructors
            blocked_range2d(
                RowValue row_begin, RowValue row_end,
                typename row_range_type::size_type row_grainsize,
                ColValue col_begin, ColValue col_end,
                typename col_range_type::size_type col_grainsize);
            blocked_range2d( RowValue row_begin, RowValue row_end,
                            ColValue col_begin, ColValue col_end );

            // Splitting constructors
            blocked_range2d( blocked_range2d& r, split );
            blocked_range2d( blocked_range2d& r, proportional_split proportion );

            // Capacity
            bool empty() const;

            // Access
```

(continues on next page)

(continued from previous page)

```

        bool is_divisible() const;
        const row_range_type& rows() const;
        const col_range_type& cols() const;
    };

    } // namespace tbb
} // namespace oneapi

```

Requirements:

- The *RowValue* and *ColValue* must meet the *blocked_range requirements*

Member types

```
using row_range_type = blocked_range<RowValue>;
```

The type of the row values.

```
using col_range_type = blocked_range<ColValue>;
```

The type of the column values.

Member functions

```
blocked_range2d(
    RowValue row_begin, RowValue row_end,
    typename row_range_type::size_type row_grainsize,
    ColValue col_begin, ColValue col_end,
    typename col_range_type::size_type col_grainsize);
```

Effects: Constructs a `blocked_range2d` representing a two-dimensional space of values. The space is the half-open Cartesian product $[\text{row_begin}, \text{row_end}) \times [\text{col_begin}, \text{col_end})$, with the given grain sizes for the rows and columns.

Example: The statement `blocked_range2d<char,int> r('a', 'z'+1, 3, 0, 10, 2);` constructs a two-dimensional space that contains all value pairs of the form (i, j) , where i ranges from 'a' to 'z' with a grain size of 3, and j ranges from 0 to 9 with a grain size of 2.

```
blocked_range2d(RowValue row_begin, RowValue row_end,
                ColValue col_begin, ColValue col_end);
```

Same as `blocked_range2d(row_begin, row_end, 1, col_begin, col_end, 1)`.

```
blocked_range2d(blocked_range2d& range, split);
```

Basic splitting constructor.

Requirements: `is_divisible()` is true.

Effects: Partitions `range` into two subranges. The newly constructed `blocked_range2d` is approximately the second half of the original range, and `range` is updated to be the remainder. Each subrange has the same grain size as the original range. Splitting is done either by rows or columns. The choice of which axis to split is intended to cause, after repeated splitting, the subranges to approach the aspect ratio of the respective row and column grain sizes.

```
blocked_range2d(blocked_range2d& range, proportional_split proportion);
```

Proportional splitting constructor.

Requirements: `is_divisible()` is true.

Effects: Partitions `range` into two subranges in the given `proportion` across one of its axes. The choice of which axis to split is made in the same way as for the basic splitting constructor; then, proportional splitting is done for the chosen axis. The second axis and the grain sizes for each subrange remain the same as in the original range.

```
bool empty() const;
```

Effects: Determines if `range` is empty.

Returns: `rows().empty() || cols().empty()`

```
bool is_divisible() const;
```

Effects: Determines if `range` can be split into subranges.

Returns: `rows().is_divisible() || cols().is_divisible()`

```
const row_range_type& rows() const;
```

Returns: Range containing the rows of the value space.

```
const col_range_type& cols() const;
```

Returns: Range containing the columns of the value space.

- [blocked_range](#)

blocked_range3d

[algorithms.blocked_range3d]

Class template that represents a recursively divisible three-dimensional half-open interval.

A `blocked_range3d` is the three-dimensional extension of `blocked_range2d`.

```
namespace oneapi {
    namespace tbb {
        template<typename PageValue, typename RowValue=PageValue, typename ColValue=RowValue>
        class blocked_range3d {
        public:
            // Types
            using page_range_type = blocked_range<PageValue>;
            using row_range_type = blocked_range<RowValue>;
            using col_range_type = blocked_range<ColValue>;

            // Constructors
            blocked_range3d(
                PageValue page_begin, PageValue page_end,
                typename page_range_type::size_type page_grainsize,
```

(continues on next page)

(continued from previous page)

```

        RowValue row_begin, RowValue row_end,
        typename row_range_type::size_type row_grainsize,
        ColValue col_begin, ColValue col_end,
        typename col_range_type::size_type col_grainsize );
blocked_range3d( PageValue page_begin, PageValue page_end
                RowValue row_begin, RowValue row_end,
                ColValue col_begin, ColValue col_end );
blocked_range3d( blocked_range3d& r, split );
blocked_range3d( blocked_range3d& r, proportional_split& proportion );

    // Capacity
    bool empty() const;

    // Access
    bool is_divisible() const;
    const page_range_type& pages() const;
    const row_range_type& rows() const;
    const col_range_type& cols() const;
};

} // namespace tbb
} // namespace oneapi

```

Requirements:

- The *PageValue*, *RowValue* and *ColValue* must meet the *blocked_range requirements*

Member types

```
using page_range_type = blocked_range<PageValue>;
```

The type of the page values.

```
using row_range_type = blocked_range<RowValue>;
```

The type of the row values.

```
using col_range_type = blocked_range<ColValue>;
```

The type of the column values.

Member functions

```
blocked_range3d(PageValue page_begin, PageValue page_end,
               typename page_range_type::size_type page_grainsize,
               RowValue row_begin, RowValue row_end,
               typename row_range_type::size_type row_grainsize,
               ColValue col_begin, ColValue col_end,
               typename col_range_type::size_type col_grainsize);

```

Effects: Constructs a `blocked_range3d` representing a three-dimensional space of values. The space is the half-open Cartesian product $[\text{page_begin}, \text{page_end}) \times [\text{row_begin}, \text{row_end}) \times [\text{col_begin}, \text{col_end})$, with the given grain sizes for the pages, rows and columns.

Example: The statement `blocked_range3d<int, char, int> r(0, 6, 2, 'a', 'z'+1, 3, 0, 10, 2);` constructs a three-dimensional space that contains all value pairs of the form (i, j, k) , where i ranges from 0 to 6 with a grain size of 2, j ranges from 'a' to 'z' with a grain size of 3, and k ranges from 0 to 9 with a grain size of 2.

```
blocked_range3d(PageValue page_begin, PageValue page_end,
               RowValue row_begin, RowValue row_end,
               ColValue col_begin, ColValue col_end);
```

Same as `blocked_range3d(page_begin, page_end, 1, row_begin, row_end, 1, col_begin, col_end, 1)`.

```
blocked_range3d( blocked_range3d& range, split );
```

Basic splitting constructor.

Requirements: `is_divisible()` is true.

Effects: Partitions `range` into two subranges. The newly constructed `blocked_range3d` is approximately the second half of the original range, and `range` is updated to be the remainder. Each subrange has the same grain size as the original range. Splitting is done either by pages, rows, or columns. The choice of which axis to split is intended to cause, after repeated splitting, the subranges to approach the aspect ratio of the respective page, row, and column grain sizes.

```
blocked_range3d( blocked_range3d& range, proportional_split proportion );
```

Proportional splitting constructor.

Requirements: `is_divisible()` is true.

Effects: Partitions `range` into two subranges in the given `proportion` across one of its axes. The choice of which axis to split is made in the same way as for the basic splitting constructor; then, proportional splitting is done for the chosen axis. The second axis and the grain sizes for each subrange remain the same as in the original range.

```
bool empty() const;
```

Effects: Determines if `range` is empty.

Returns: `pages.empty() || rows().empty() || cols().empty()`

```
bool is_divisible() const;
```

Effects: Determines if the range can be split into subranges.

Returns: `pages().is_divisible() || rows().is_divisible() || cols().is_divisible()`

```
const page_range_type& pages() const;
```

Returns: Range containing the pages of the value space.

```
const row_range_type& rows() const;
```

Returns: Range containing the rows of the value space.

```
const col_range_type& cols() const;
```

Returns: Range containing the columns of the value space.

Partitioners

A partitioner specifies how a loop template should partition its work among threads.

auto_partitioner

[algorithms.auto_partitioner]

Specifies that a parallel loop should optimize its range subdivision based on work-stealing events.

A loop template with an `auto_partitioner` attempts to minimize range splitting while providing ample opportunities for work stealing.

The range subdivision is initially limited to *S* subranges, where *S* is proportional to the number of threads specified by the *global_control* or *task_arena*. Each of these subranges is not divided further unless it is stolen by an idle thread. If stolen, it is further subdivided to create additional subranges. Thus a loop template with an `auto_partitioner` creates additional subranges only when it is necessary to balance a load.

An `auto_partitioner` performs sufficient splitting to balance load, not necessarily splitting as finely as `Range::is_divisible` permits. When used with classes such as `blocked_range`, the selection of an appropriate grain size is less important, and often acceptable performance can be achieved with the default grain size of 1.

The `auto_partitioner` class satisfies the *CopyConstructible* requirement from the ISO C++ [utility.arg.requirements] section.

Tip: When using `auto_partitioner` and a `blocked_range` for a parallel loop, the body may receive a subrange larger than the grain size of the `blocked_range`. Therefore, do not assume that the grain size is an upper bound of the subrange size. Use `simple_partitioner` if an upper bound is required.

```
// Defined in header <oneapi/tbb/partitioner.h>

namespace oneapi {
    namespace tbb {

        class auto_partitioner {
        public:
            auto_partitioner() = default;
            ~auto_partitioner() = default;
        };

    } // namespace tbb
} // namespace oneapi
```

affinity_partitioner

[algorithms.affinity_partitioner]

Hints that loop iterations should be assigned to threads in a way that optimizes for cache affinity.

An `affinity_partitioner` hints that execution of a loop template should use the same task affinity pattern for splitting the work as used by previous execution of the loop (or another loop) with the same `affinity_partitioner` object.

`affinity_partitioner` uses proportional splitting when it is enabled for a *Range* type.

Unlike the other partitioners, it is important that the same `affinity_partitioner` object be passed to the loop templates to be optimized for affinity.

The `affinity_partitioner` class satisfies the *CopyConstructible* requirement from the ISO C++ [utility.arg.requirements] section.

```
// Defined in header <oneapi/tbb/partitioner.h>

namespace oneapi {
    namespace tbb {

        class affinity_partitioner {
        public:
            affinity_partitioner() = default;
            ~affinity_partitioner() = default;
        };

    } // namespace tbb
} // namespace oneapi
```

See also:

- *Range named requirement*

static_partitioner

[algorithms.static_partitioner]

Specifies that a parallel algorithm should distribute the work uniformly across threads and should not do additional load balancing.

An algorithm with a `static_partitioner` distributes the range across threads in subranges of approximately equal size. The number of subranges is equal to the number of threads that can possibly participate in task execution, as specified by *global_contol* or *task_arena* classes. These subranges are not further split.

Caution: The regularity of subrange sizes is not guaranteed if the range type does not support proportional splitting, or if the grain size is set larger than the size of the range divided by the number of threads participating in task execution.

In addition, `static_partitioner` uses a deterministic task affinity pattern to hint the task scheduler how the subranges should be assigned to threads.

The `static_partitioner` class satisfies the *CopyConstructible* requirement from the ISO C++ [utility.arg.requirements] section.

Tip: Use `static_partitioner` to:

- Parallelize small well-balanced workloads where enabling additional load balancing opportunities brings more overhead than performance benefits.
- Port OpenMP* parallel loops with `schedule(static)` if deterministic work partitioning across threads is important.

```
// Defined in header <oneapi/tbb/partitioner.h>

namespace oneapi {
    namespace tbb {

        class static_partitioner {
        public:
            static_partitioner() = default;
            ~static_partitioner() = default;
        };

    } // namespace tbb
} // namespace oneapi
```

See also:

- *Range named requirement*

simple_partitioner

[algorithms.simple_partitioner]

Specifies that a parallel loop should recursively split its range until it cannot be further subdivided.

A `simple_partitioner` specifies that a loop template should recursively divide its range until for each subrange r , the condition `!r.is_divisible()` holds. This is the default behavior of the loop templates that take a range argument.

The `simple_partitioner` class satisfies the *CopyConstructible* requirement from the ISO C++ [utility.arg.requirements] section.

Tip: When using `simple_partitioner` and a `blocked_range` for a parallel loop, make sure to specify an appropriate grain size for the `blocked_range`. The default grain size is 1, which may make the subranges much too small for efficient execution.

```
// Defined in header <oneapi/tbb/partitioner.h>

namespace oneapi {
    namespace tbb {

        class simple_partitioner {
        public:
            simple_partitioner() = default;
            ~simple_partitioner() = default;
        };
    };
};
```

(continues on next page)

(continued from previous page)

```

    } // namespace tbb
} // namespace oneapi

```

- *Range named requirement*

Split Tags

proportional split

[algorithms.proportional_split]

Type of an argument for a proportional splitting constructor of *Range*.

An argument of type `proportional_split` may be used by classes that satisfy *Range requirements* to distinguish a proportional splitting constructor from a basic splitting constructor and from a copy constructor, and to suggest a ratio in which a particular instance of the class should be split.

```

// Defined in header <oneapi/tbb/blocked_range.h>
// Defined in header <oneapi/tbb/blocked_range2d.h>
// Defined in header <oneapi/tbb/blocked_range3d.h>
// Defined in header <oneapi/tbb/partitioner.h>
// Defined in header <oneapi/tbb/parallel_for.h>
// Defined in header <oneapi/tbb/parallel_reduce.h>
// Defined in header <oneapi/tbb/parallel_scan.h>

namespace oneapi {
    namespace tbb {
        class proportional_split {
        public:
            proportional_split(std::size_t _left = 1, std::size_t _right = 1);

            std::size_t left() const;
            std::size_t right() const;

            explicit operator split() const;
        };
    } // namespace tbb
} // namespace oneapi

```

Member functions

proportional_split(std::size_t _left = 1, std::size_t _right = 1)

Constructs a proportion with the ratio specified by coefficients *_left* and *_right*.

std::size_t **left**() const

Returns the size of the left part of the proportion.

std::size_t **right**() const

Returns the size of the right part of the proportion.

explicit **operator split()** const

Makes `proportional_split` convertible to the `split` type to use with ranges that do not support proportional splitting.

See also:

- [split](#)
- [Range requirements](#)

split

[algorithms.split]

Type of an argument for a splitting constructor of *Range*. An argument of type `split` is used to distinguish a splitting constructor from a copy constructor.

```
// Defined in header <oneapi/tbb/blocked_range.h>
// Defined in header <oneapi/tbb/blocked_range2d.h>
// Defined in header <oneapi/tbb/blocked_range3d.h>
// Defined in header <oneapi/tbb/partitioner.h>
// Defined in header <oneapi/tbb/parallel_for.h>
// Defined in header <oneapi/tbb/parallel_reduce.h>
// Defined in header <oneapi/tbb/parallel_scan.h>

class split;
```

9.2.3 Flow Graph

[flow_graph]

In addition to loop parallelism, the oneAPI Threading Building Blocks (oneTBB) library also supports graph parallelism. With this feature, highly scalable and completely sequential graphs can be created.

There are three types of components used to implement a graph:

- A `graph` class instance
- Nodes
- Ports and edges

Graph Class

The `graph` class instance owns all the tasks created on behalf of the flow graph. Users can wait on the graph if they need to wait for the completion of all of the tasks related to the flow graph execution. Users can also register external interactions with the graph and run tasks under the ownership of the flow graph.

graph

[flow_graph.graph]

Class that serves as a handle to a flow graph of nodes and edges.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    class graph {
    public:
        graph();
        graph(task_group_context& context);
        ~graph();

        void wait_for_all();

        void reset(reset_flags f = rf_reset_protocol);
        void cancel();
        bool is_cancelled();
        bool exception_thrown();
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

reset_flags enumeration

reset_flags Enumeration

[flow_graph.reset_flags]

A reset_flags enumeration represents flags that can be passed to the `graph::reset()` function.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    enum reset_flags {
        rf_reset_protocol = /*implementation-defined*/,
        rf_reset_bodies = /*implementation-defined*/,
        rf_clear_edges = /*implementation-defined*/
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

Its enumerated values and their meanings are as follows:

- `rf_reset_protocol` - All buffers are emptied, internal state of nodes reinitialized. All calls to `reset()` perform these actions.
- `rf_reset_bodies` - When nodes with bodies are created, the body specified in the constructor is copied and preserved. When `rf_reset_bodies` is specified, the current body of the node is deleted and replaced with a copy of the body saved during construction.

Caution: If the body contains state which has an external component (such as a file descriptor), the node may not behave the same on re-execution of the graph after body replacement. In this case, the node should be re-created.

- `rf_clear_edges` - All edges are removed from the graph.

Member functions

graph(*task_group_context* &context)

Constructs a graph with no nodes. If `context` is specified, the graph tasks are executed in this context. By default, the graph is executed in a bound context of its own.

~graph()

Calls `wait_for_all()` on the graph, then destroys the graph.

void **wait_for_all**()

Blocks execution until all tasks associated with the graph have completed or cancelled.

void **reset**(reset_flags f = `rf_reset_protocol`)

Resets the graph according to the specified flags. Flags to `reset()` can be combined with bitwise-or.

Note: `reset()` is a thread-unsafe operation, don't call it concurrently.

void **cancel**()

Cancels all tasks in the graph.

bool **is_cancelled**()

Returns: `true` if the graph was cancelled during the last call to `wait_for_all()`; `false`, otherwise.

bool **exception_thrown**()

Returns: `true` if during the last call to `wait_for_all()` an exception was thrown; `false`, otherwise.

Nodes

Abstract Interfaces

To be used as a graph node type, a class needs to inherit certain abstract types and implement the corresponding interfaces. `graph_node` is the base class for any other node type; its interfaces always have to be implemented. If a node sends messages to other nodes, it has to implement the `sender` interface, while with the `receiver` interface the node may accept messages. For nodes that have multiple inputs and/or outputs, each input port is a `receiver` and each output port is a `sender`.

graph_node

[flow_graph.graph_node]

A base class for all graph nodes.

```

namespace oneapi {
namespace tbb {
namespace flow {

    class graph_node {
    public:
        explicit graph_node( graph &g );
        virtual ~graph_node();
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

The `graph_node` class is a base class for all flow graph nodes. The virtual destructor allows flow graph nodes to be destroyed through pointers to `graph_node`. For example, a `vector< graph_node * >` can be used to hold the addresses of flow graph nodes that will need to be destroyed later.

sender

[flow_graph.sender]

A base class for all nodes that may send messages.

```

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename T >
    class sender { /*unspecified*/ };

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

The `T` type is a message type.

receiver

[flow_graph.receiver]

A base class for all nodes that may receive messages.

```

namespace oneapi {
namespace tbb {
namespace flow {

```

(continues on next page)

(continued from previous page)

```

template< typename T >
class receiver { /*unspecified*/ };

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

The T type is a message type.

Properties

Every node in a flow graph has its own properties.

Forwarding and Buffering

[[flow_graph.forwarding_and_buffering](#)]

Forwarding

In a flow: :graph, nodes that forward messages to successors have one of two possible forwarding policies, which are a property of the node:

- **broadcast-push** - the message will be pushed to as many successors as will accept the message. If no successor accepts the message, the fate of the message depends on the output buffering policy of the node.
- **single-push** - if the message is accepted by a successor, no further push of that message will occur. If a successor rejects the message, the next successor in the set is tried. This continues until a successor accepts the message, or all successors have been attempted. If no successor accepts the message, it will be retained for a possible future resend. Message that is successfully transferred to a successor is removed from the node.

Buffering

There are two policies for handling a message that cannot be pushed to any successor:

- **buffering** - if no successor accepts a message, it is stored so subsequent node processing can use it. Nodes that buffer outputs have “yes” in the “try_get()?” column below.
- **discarding** - if no successor accepts a message, it is discarded and has no further effect on graph execution. Nodes that discard outputs have “no” in the “try_get()?” column below.

The following table lists the policies of each node:

Table 4: Buffering and Forwarding properties summary

Node	try_get()?	Forwarding
Functional Nodes		
input_node	yes	broadcast-push
function_node<rejecting>	no	broadcast-push
function_node<queueing>	no	broadcast-push
continue_node	no	broadcast-push
multifunction_node<rejecting>	no	broadcast-push
multifunction_node<queueing>	no	broadcast-push
Buffering Nodes		
buffer_node	yes	single-push
priority_queue_node	yes	single-push
queue_node	yes	single-push
sequencer_node	yes	single-push
overwrite_node	yes	broadcast-push
write_once_node	yes	broadcast-push
Split/Join Nodes		
join_node<queueing>	yes	broadcast-push
join_node<reserving>	yes	broadcast-push
join_node<tag_matching>	yes	broadcast-push
split_node	no	broadcast-push
indexer_node	no	broadcast-push
Other Nodes		
broadcast_node	no	broadcast-push
limiter_node	no	broadcast-push

Functional Nodes

Functional nodes do computations in response to input messages (if any), and send the result or a signal to their successors.

continue_node

[flow_graph.continue_node]

A node that executes a specified body object when triggered.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename Output, typename Policy = /*implementation-defined*/ >
    class continue_node : public graph_node, public receiver<continue_msg>, public sender
    ↪<Output> {
    public:
        template<typename Body>
        continue_node( graph &g, Body body, node_priority_t priority = no_priority );
        template<typename Body>
```

(continues on next page)

(continued from previous page)

```

continue_node( graph &g, Body body, Policy /*unspecified*/ = Policy(),
               node_priority_t priority = no_priority );

template<typename Body>
continue_node( graph &g, int number_of_predecessors, Body body,
               node_priority_t priority = no_priority );
template<typename Body>
continue_node( graph &g, int number_of_predecessors, Body body,
               Policy /*unspecified*/ = Policy(), node_priority_t priority = no_
↳priority );

continue_node( const continue_node &src );
~continue_node();

bool try_put( const input_type &v );
bool try_get( output_type &v );
};

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The type Output must meet the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard section.
- The type Policy can be specified as *lightweight policy* or defaulted.
- The type Body must meet the *ContinueNodeBody requirements*.

A `continue_node` is a `graph_node`, `receiver<continue_msg>`, and `sender<Output>`.

This node is used for nodes that wait for their predecessors to complete before executing, but no explicit data is passed across the incoming edges.

A `continue_node` maintains an internal threshold that defines the number of predecessors. This value can be provided at construction. Call of the *make_edge function* with `continue_node` as a receiver increases its threshold. Call of the *remove_edge function* with `continue_node` as a receiver decreases it.

Each time the number of `try_put()` calls reaches the defined threshold, node's body is called and the node starts counting the number of `try_put()` calls from the beginning.

`continue_node` has a *discarding* and *broadcast-push properties*.

The body object passed to a `continue_node` is copied. Updates to member variables do not affect the original object used to construct the node. If the state held within a body object must be inspected from outside of the node, the *copy_body function* can be used to obtain an updated copy.

Member functions

```
template<typename Body>
continue_node( graph &g, Body body, node_priority_t priority = no_priority );
```

Constructs a `continue_node` that invokes `body`. The internal threshold is set to 0.

This function specifies *node priority*.

```
template<typename Body>
continue_node( graph &g, Body body, Policy /*unspecified*/ = Policy(),
              node_priority_t priority = no_priority );
```

Constructs a `continue_node` that invokes `body`. The internal threshold is set to 0.

This function specifies *lightweight policy* and *node priority*.

```
template<typename Body>
continue_node( graph &g, int number_of_predecessors, Body body,
              node_priority_t priority = no_priority );
```

Constructs a `continue_node` that invokes `body`. The internal threshold is set to `number_of_predecessors`.

This function specifies *node priority*.

```
template<typename Body>
continue_node( graph &g, int number_of_predecessors, Body body,
              Policy /*unspecified*/ = Policy(), node_priority_t priority = no_priority,
              ↪ );
```

Constructs a `continue_node` that invokes `body`. The internal threshold is set to `number_of_predecessors`.

This function specifies *lightweight policy* and *node priority*.

```
template<typename Body>
continue_node( graph &g, int number_of_predecessors, Body body );
```

Constructs a `continue_node` that invokes `body`. The internal threshold is set to `number_of_predecessors`.

```
continue_node( const continue_node &src )
```

Constructs a `continue_node` that has the same initial state that `src` had after its construction. It does not copy the current count of `try_puts` received, or the current known number of predecessors. The `continue_node` that is constructed has a reference to the same `graph` object as `src`, has a copy of the initial body used by `src`, and only has a non-zero threshold if `src` is constructed with a non-zero threshold.

The new body object is copy-constructed from a copy of the original body provided to `src` at its construction.

```
bool try_put( const Input &v )
```

Increments the count of `try_put()` calls received. If the incremented count is equal to the number of known predecessors, performs the body function object execution. It does not wait for the execution of the body to complete.

Returns: true

```
bool try_get( Output &v )
```

Returns: false

Deduction Guides

```
template <typename Body, typename Policy>
continue_node(graph&, Body, Policy, node_priority_t = no_priority)
    -> continue_node<continue_output_t<std::invoke_result_t<Body, continue_msg>>, Policy>
    ↪;

template <typename Body, typename Policy>
continue_node(graph&, int, Body, Policy, node_priority_t = no_priority)
    -> continue_node<continue_output_t<std::invoke_result_t<Body, continue_msg>>, Policy>
    ↪;

template <typename Body>
continue_node(graph&, Body, node_priority_t = no_priority)
    -> continue_node<continue_output_t<std::invoke_result_t<Body, continue_msg>>, /
    ↪*default-policy*/>;

template <typename Body>
continue_node(graph&, int, Body, node_priority_t = no_priority)
    -> continue_node<continue_output_t<std::invoke_result_t<Body, continue_msg>>, /
    ↪*default-policy*/>;
```

Where:

- `continue_output_t<Output>` is an alias to *Output* template argument type. If *Output* specified as void, `continue_output_t<Output>` is an alias to `continue_msg` type.

Example

A set of `continue_nodes` forms a *Dependency Flow Graph*.

function_node

[flow_graph.function_node]

A node that executes a user-provided body on incoming messages.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template < typename Input, typename Output = continue_msg, typename Policy = /
↳ *implementation-defined*/ >
    class function_node : public graph_node, public receiver<Input>, public sender
↳ <Output> {
    public:
        template<typename Body>
        function_node( graph &g, size_t concurrency, Body body, Policy /*unspecified*/ =
↳ Policy(),
                        node_priority_t priority = no_priority );
        template<typename Body>
        function_node( graph &g, size_t concurrency, Body body,
                        node_priority_t priority = no_priority );
        ~function_node();

        function_node( const function_node &src );

        bool try_put( const Input &v );
        bool try_get( Output &v );
    };
} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The Input type must meet the *DefaultConstructible* requirements from [defaultconstructible] and the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard sections.
- The Output type must meet the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard section.
- The type Policy may be specified as *lightweight*, *queueing and rejecting policies* or defaulted.
- The type Body must meet the *FunctionNodeBody requirements*.

function_node has a user-settable concurrency limit. It can be set to one of *predefined values*. The user can also provide a value of type `std::size_t` to limit concurrency to a value between 1 and `tbb::flow::unlimited`.

Messages that cannot be immediately processed due to concurrency limits are handled according to the *Policy* template argument.

function_node is a `graph_node`, `receiver<Input>`, and `sender<Output>`.

function_node has a *discarding* and *broadcast-push properties*.

The body object passed to a `function_node` is copied. Updates to member variables do not affect the original object used to construct the node. If the state held within a body object must be inspected from outside of the node, the `copy_body` function can be used to obtain an updated copy.

Member functions

```
template<typename Body>
function_node( graph &g, size_t concurrency, Body body,
              node_priority_t priority = no_priority );
```

Constructs a `function_node` that invokes a copy of `body`. Most of concurrency calls to `body` can be made concurrently.

Use this function to specify *node priority*.

```
template<typename Body>
function_node( graph &g, size_t concurrency, Body body, Policy /*unspecified*/ =
↳Policy(),
              node_priority_t priority = no_priority );
```

Constructs a `function_node` that invokes a copy of `body`. Most of concurrency calls to `body` can be made concurrently.

Use this function to specify *policy* and *node priority*.

```
function_node( const function_node &src )
```

Constructs a `function_node` that has the same initial state that `src` had when it was constructed. The `function_node` that is constructed has a reference to the same `graph` object as `src`, has a copy of the initial body used by `src`, and has the same concurrency threshold as `src`. The predecessors and successors of `src` are not copied.

The new body object is copy-constructed from a copy of the original body provided to `src` at its construction. Changes made to member variables in `src`'s body after the construction of `src` do not affect the body of the new `function_node`.

```
bool try_put( const Input &v )
```

If the concurrency limit allows, executes the user-provided body on the incoming message `v`. Otherwise, depending on the policy of the node, either queues the incoming message `v` or rejects it.

Returns: `true` if the input was accepted; and `false`, otherwise.

```
bool try_get( Output &v )
```

Returns: `false`

Deduction Guides

```

template <typename Body, typename Policy>
function_node(graph&, size_t, Body, Policy, node_priority_t = no_priority)
    ->function_node<std::decay_t<input_t<Body>>, output_t<Body>, Policy>;

template <typename Body>
function_node(graph&, size_t, Body, node_priority_t = no_priority)
    ->function_node<std::decay_t<input_t<Body>>, output_t<Body>, /*default-policy*/>;

```

Where:

- `input_t` is an alias to Body input argument type.
- `output_t` is an alias to Body return type.

Example

Data Flow Graph example illustrates how `function_node` performs computation on input data and passes the result to successors.

input_node

[flow_graph.input_node]

A node that generates messages by invoking the user-provided functor and broadcasts the result to all of its successors.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template < typename Output >
    class input_node : public graph_node, public sender<Output> {
    public:
        template< typename Body >
        input_node( graph &g, Body body );
        input_node( const input_node &src );
        ~input_node();

        void activate();
        bool try_get( Output &v );
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The Output type must meet the *DefaultConstructible* requirements from [defaultconstructible], *CopyConstructible* requirements from [copyconstructible] and *CopyAssignable* requirements from [copyassignable] ISO C++ Standard sections.

- The type `Body` must meet the *InputNodeBody requirements*.

This node can have no predecessors. It executes a user-provided `body` function object to generate messages that are broadcast to all successors. It is a serial node and never calls its `body` concurrently. This node can buffer a single item. If no successor accepts an item that it has generated, the message is buffered and provided to successors before a new item is generated.

`input_node` is a `graph_node` and `sender<Output>`.

`input_node` has a *buffering* and *broadcast-push properties*.

An `input_node` continues to invoke `body` and broadcast messages until the `body` toggles `fc.stop()` or it has no valid successors. A message may be generated and then rejected by all successors. In this case, the message is buffered and will be the next message sent once a successor is added to the node or `try_get` is called. Calls to `try_get` return a message from the buffer, or invoke `body` to attempt to generate a new message. A call to `body` is made only when the buffer is empty.

The `body` object passed to an `input_node` is copied. Updates to member variables do not affect the original object used to construct the node. If the state held within a `body` object must be inspected from outside of the node, the *copy_body function* can be used to obtain an updated copy.

Member functions

template<typename `Body`>

`input_node`(*graph* &g, *Body* body)

Constructs an `input_node` that invokes `body`. By default, the node is created in an inactive state, which means that messages are not generated until a call to `activate` is made.

`input_node`(const *input_node* &src)

Constructs an `input_node` that has the same initial state that `src` had when it was constructed. The `input_node` that is constructed has a reference to the same `graph` object as `src`, has a copy of the initial `body` used by `src`, and has the same initial active state as `src`. The successors of `src` are not copied.

The new `body` object is copy-constructed from a copy of the original `body` provided to `src` at its construction. Changes made to member variables in `src` `body` after the construction of `src` do not affect the `body` of the new `input_node`.

void `activate`()

Sets the `input_node` to the active state, which enables messages generation.

bool `try_get`(`Output` &v)

Copies the message from the buffer to `v` if available, or, if the node is in active state, invokes `body` to attempt to generate a new message that will be copied into `v`.

Returns: `true` if a message is copied to `v`; `false`, otherwise.

Deduction Guides

```
template <typename Body>
input_node(graph&, Body) -> input_node<std::decay_t<input_t<Body>>>>;
```

Where:

- `input_t` is an alias to `Body` input argument type.

multifunction_node

[flow_graph.multifunction_node]

A node that used for nodes that receive messages at a single input port and may generate one or more messages that are broadcast to successors.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template < typename Input, typename Output, typename Policy = /*implementation-
↳defined*/ >
    class multifunction_node : public graph_node, public receiver<Input> {
    public:
        template<typename Body>
        multifunction_node( graph &g, size_t concurrency, Body body, Policy /
↳*unspecified*/ = Policy(),
                            node_priority_t priority = no_priority );
        template<typename Body>
        multifunction_node( graph &g, size_t concurrency, Body body,
                            node_priority_t priority = no_priority );

        multifunction_node( const multifunction_node& other );
        ~multifunction_node();

        bool try_put( const Input &v );

        using output_ports_type = /*implementation-defined*/;
        output_ports_type& output_ports();
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

Requirements:

- The Input type must meet the *DefaultConstructible* requirements from [defaultconstructible] and the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard sections.
- The type Policy can be specified as *lightweight*, *queueing and rejecting policies* or defaulted.
- The type Body must meet the *MultifunctionNodeBody requirements*.

multifunction_node has a user-settable concurrency limit. It can be set to one of *predefined values*. The user can also provide a value of type `std::size_t` to limit concurrency to a value between 1 and `tbb::flow::unlimited`.

When the concurrency limit allows, it executes the user-provided body on incoming messages. The body can create one or more output messages and broadcast them to successors.

multifunction_node is a `graph_node`, `receiver<InputType>` and has a tuple of `sender<Output>` outputs.

multifunction_node has a *discarding* and *broadcast-push properties*.

The body object passed to a multifunction_node is copied. Updates to member variables do not affect the original

object used to construct the node. If the state held within a body object must be inspected from outside of the node, the *copy_body_function* can be used to obtain an updated copy.

Member types

`output_ports_type` is an alias to a `std::tuple` of output ports.

Member functions

```
template<typename Body>
multifunction_node( graph &g, size_t concurrency, Body body,
                   node_priority_t priority = no_priority );
```

Constructs a `multifunction_node` that invokes a copy of `body`. Most concurrency calls to `body` can be made concurrently.

Use this function to specify *node priority*.

```
template<typename Body>
multifunction_node( graph &g, size_t concurrency, Body body, Policy /*unspecified*/ =_
↳Policy(),
                   node_priority_t priority = no_priority );
```

Constructs a `multifunction_node` that invokes a copy of `body`. Most concurrency calls to `body` can be made concurrently.

Use this function to specify a *policy* and *node priority*.

```
multifunction_node( const multifunction_node &src )
```

Constructs a `multifunction_node` that has the same initial state that `other` had when it was constructed. The `multifunction_node` that is constructed has a reference to the same `graph` object as `other`, has a copy of the initial body used by `other`, and has the same concurrency threshold as `other`. The predecessors and successors of `other` are not copied.

The new body object is copy-constructed from a copy of the original body provided to `other` at its construction. Changes made to member variables in `other` body after the construction of `other` do not affect the body of the new `multifunction_node`.

```
bool try_put( const input_type &v )
```

If the concurrency limit allows, executes the user-provided body on the incoming message `v`. Otherwise, depending on the policy of the node, either queues the incoming message `v` or rejects it.

Returns: `true` if the input was accepted; `false`, otherwise.

```
output_ports_type& output_ports();
```

Returns: a `std::tuple` of output ports.

async_node

[flow_graph.async_node]

A node that enables communication between a flow graph and an external activity managed by the user or another runtime.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template < typename Input, typename Output, typename Policy = /*implemetation-
↳defined*/ >
    class async_node : public graph_node, public receiver<Input>, public sender<Output> {
    public:
        template<typename Body>
        async_node( graph &g, size_t concurrency, Body body, Policy /*unspecified*/ =
↳Policy(),
                    node_priority_t priority = no_priority );
        template<typename Body>
        async_node( graph &g, size_t concurrency, Body body, node_priority_t priority =
↳no_priority );

        async_node( const async_node& src );
        ~async_node();

        using gateway_type = /*implementation-defined*/;
        gateway_type& gateway();

        bool try_put( const input_type& v );
        bool try_get( output_type& v );
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

Requirements:

- The Input type must meet the *DefaultConstructible* requirements from [defaultconstructible] and the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard sections.
- The type Policy can be specified as *lightweight*, *queueing and rejecting policies* or defaulted.
- The type Body must meet the *AsyncNodeBody requirements*.

async_node executes a user-provided body on incoming messages. The body typically submits the messages to an external activity for processing outside of the graph. It is responsibility of body to be able to pass the message to an external activity. This node also provides the gateway_type interface that allows an external activity to communicate with the flow graph.

async_node is a graph_node, receiver<Input>, and a sender<Output>.

async_node has a *discarding* and *broadcast-push properties*.

`async_node` has a user-settable concurrency limit, which can be set to one of *predefined values*. The user can also provide a value of type `std::size_t` to limit concurrency to a value between 1 and *tbb::flow::unlimited*.

The body object passed to a `async_node` is copied. Updates to member variables do not affect the original object used to construct the node. If the state held within a body object must be inspected from outside of the node, the *copy_body* function can be used to obtain an updated copy.

Member types

`gateway_type` meets the *GatewayType requirements*.

Member functions

```
template<typename Body>
async_node( graph &g, size_t concurrency, Body body,
            node_priority_t priority = no_priority );
```

Constructs an `async_node` that invokes a copy of `body`. The concurrency value limits the number of simultaneous body invocations for the node.

This function specifies *node priority*.

```
template<typename Body>
async_node( graph &g, size_t concurrency, Body body, Policy /*unspecified*/ = Policy(),
            node_priority_t priority = no_priority );
```

Constructs a `async_node` that invokes a copy of `body`. Most concurrency calls to `body` can be made concurrently.

This function specifies a *policy* and *node priority*.

```
async_node( const async_node &src )
```

Constructs an `async_node` that has the same initial state that `src` had when it was constructed. The `async_node` that is constructed has a reference to the same `graph` object as `src`, has a copy of the initial body used by `src`, and has the same concurrency threshold as `src`. The predecessors and successors of `src` are not copied.

The new body object is copy-constructed from a copy of the original body provided to `src` at its construction. Changes made to member variables in `src`'s body after the construction of `src` do not affect the body of the new `async_node`.

```
gateway_type& gateway()
```

Returns reference to the `gateway_type` interface.

```
bool try_put( const input_type& v )
```

If the concurrency limit allows, executes the user-provided body on the incoming message `v`. Otherwise, depending on the policy of the node, either queues the incoming message `v` or rejects it.

Returns: `true` if the input was accepted; and `false`, otherwise.

```
bool try_get( output_type& v )
```

Returns: `false`

Auxiliary

Function Nodes Policies

[`flow_graph.function_node_policies`]

`function_node`, `multifunction_node`, `async_node` and `continue_node` can be specified by the `Policy` parameter, which is represented as a set of tag classes. This parameter affects behavior of node execution.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    class queueing { /*unspecified*/ };
    class rejecting { /*unspecified*/ };
    class lightweight { /*unspecified*/ };
    class queueing_lightweight { /*unspecified*/ };
    class rejecting_lightweight { /*unspecified*/ };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

Each policy class satisfies the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard sections.

Queueing

This policy defines behavior for input messages acceptance. The `queueing` policy means that input messages that cannot be processed right away are kept to be processed when possible.

Rejecting

This policy defines behavior for input messages acceptance. The `rejecting` policy means that input messages that cannot be processed right away are not accepted by the node and it is responsibility of a predecessor to handle this.

Lightweight

This policy allows to specify that the node body takes little time to process, as a non-binding hint for an implementation to reduce overheads associated with the node execution. Any optimization applied by an implementation must have no observable side effects on the node and graph execution.

When combined with another policy, the `lightweight` policy results in extending the behavior of that other policy with the optimization hint. This rule automatically applies to functional nodes that have a default value for the `Policy` template parameter. For example, if the default value of `Policy` is `queueing`, specifying `lightweight` as the `Policy` value is equivalent to specifying `queueing_lightweight`.

The function call operator() of a node body must be `noexcept` for lightweight policies to have effect.

Example

The example below shows the application of the `lightweight` policy to a graph with a pipeline topology. It is reasonable to apply the `lightweight` policy to the second and third nodes because the bodies of these nodes are small. This allows the second and third nodes to execute without task scheduling overhead. The `lightweight` policy is not specified for the first node in order to permit concurrent invocations of the graph.

```
#include "oneapi/tbb/flow_graph.h"

int main() {
    using namespace oneapi::tbb::flow;

    graph g;

    function_node< int, int > add( g, unlimited, [](const int &v) {
        return v+1;
    } );
    function_node< int, int, lightweight > multiply( g, unlimited, [](const int &v)
↳noexcept {
        return v*2;
    } );
    function_node< int, int, lightweight > cube( g, unlimited, [](const int &v) noexcept
↳{
        return v*v*v;
    } );

    make_edge(add, multiply);
    make_edge(multiply, cube);

    for(int i = 1; i <= 10; ++i)
        add.try_put(i);
    g.wait_for_all();

    return 0;
}
```

Nodes Priorities

[flow_graph.node_priorities]

Flow graph provides interface for setting relative priorities at construction of flow graph functional nodes, guiding threads that execute the graph to prefer nodes with higher priority.

```
namespace oneapi {
namespace tbb {
namespace flow {

    typedef unsigned int node_priority_t;

    const node_priority_t no_priority = node_priority_t(0);

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

function_node, multifunction_node, async_node and continue_node has a constructor with parameter of node_priority_t type, which sets the node priority in the graph: the larger the specified value for the parameter, the higher the priority. The special constant value no_priority, which is also the default value of the parameter, switches priority off for a particular node.

For a particular graph, tasks to execute the nodes whose priority is specified have precedence over tasks for the nodes with lower or no priority value set. When looking for a task to execute, a thread chooses the one with the highest priority from those in the graph that are available for execution.

Example

The following basic example demonstrates prioritization of one path in the graph over the other, which may help to improve overall performance of the graph.

Consider executing the graph from the picture above using two threads. Assume that the nodes f1 and f3 take equal time to execute, while the node f2 takes longer. That makes the nodes bs, f2, and fe constitute the critical path in this graph. Due to the non-deterministic behavior in selection of the tasks, oneTBB might execute nodes f1 and f3 in parallel first, which would make the whole graph execution time last longer than the case when one of the threads chooses the node f2 just after the broadcast node. By setting a higher priority on node f2, threads are guided to take the critical path task earlier, thus reducing overall execution time.

```
#include <iostream>
#include <cmath>

#include "oneapi/tbb/tick_count.h"
#include "oneapi/tbb/global_control.h"

#include "oneapi/tbb/flow_graph.h"

void spin_for( double delta_seconds ) {
    oneapi::tbb::tick_count start = oneapi::tbb::tick_count::now();
    while( (oneapi::tbb::tick_count::now() - start).seconds() < delta_seconds ) ;
}

static const double unit_of_time = 0.1;
```

(continues on next page)

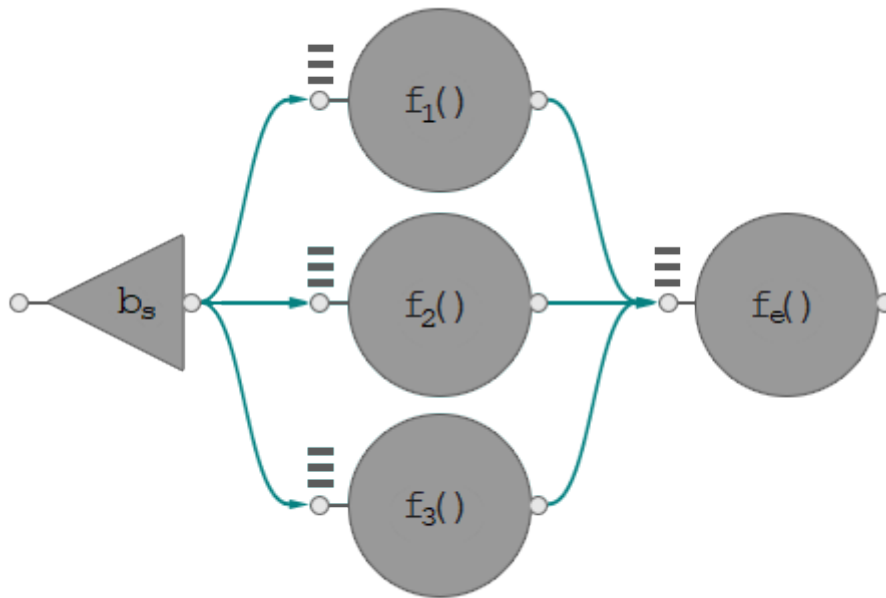

Fig. 1: Dependency flow graph with a critical path.

(continued from previous page)

```

struct Body {
    unsigned factor;
    Body( unsigned times ) : factor( times ) {}
    void operator()( const oneapi::tbb::flow::continue_msg& ) {
        // body execution takes 'factor' units of time
        spin_for( factor * unit_of_time );
    }
};

int main() {
    using namespace oneapi::tbb::flow;

    const int max_threads = 2;
    oneapi::tbb::global_control control(oneapi::tbb::global_control::max_allowed_
    ↪parallelism, max_threads);

    graph g;

    broadcast_node<continue_msg> bs(g);

    continue_node<continue_msg> f1(g, Body(5));

    // f2 is a heavy one and takes the most execution time as compared to the other.
    ↪nodes in the
    // graph. Therefore, let the graph start this node as soon as possible by.
    ↪prioritizing it over

```

(continues on next page)

(continued from previous page)

```

// the other nodes.
continue_node<continue_msg> f2(g, Body(10), node_priority_t(1));

continue_node<continue_msg> f3(g, Body(5));

continue_node<continue_msg> fe(g, Body(7));

make_edge( bs, f1 );
make_edge( bs, f2 );
make_edge( bs, f3 );

make_edge( f1, fe );
make_edge( f2, fe );
make_edge( f3, fe );

oneapi::tbb::tick_count start = oneapi::tbb::tick_count::now();

bs.try_put( continue_msg() );
g.wait_for_all();

double elapsed = std::floor((oneapi::tbb::tick_count::now() - start).seconds() /
↪unit_of_time);

std::cout << "Elapsed approximately " << elapsed << " units of time" << std::endl;

return 0;
}

```

Predefined Concurrency Limits

[flow_graph.concurrency_limits]

Predefined constants that can be used as `function_node`, `multifunction_node`, and `async_node` constructors arguments to define concurrency limit.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    std::size_t unlimited = /*implementation-defined*/;
    std::size_t serial = /*implementation-defined*/;

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

`unlimited` concurrency allows an unlimited number of invocations of the body to execute concurrently.

`serial` concurrency allows only a single call of body to execute concurrently.

copy_body

[flow_graph.copy_body]

copy_body is a function template that returns a copy of the body function object from the following nodes:

- *continue_node*
- *function_node*
- *multifunction_node*
- *input_node*
- *async_node*

```

namespace oneapi {
namespace tbb {
namespace flow {

    // Defined in header <oneapi/tbb/flow_graph.h>

    template< typename Body, typename Node >
    Body copy_body( Node &n );

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Buffering Nodes

Buffering nodes are designed to accumulate input messages and pass them to successors in a predefined order, depending on the node type.

overwrite_node

[flow_graph.overwrite_node]

A node that is a buffer of a single item that can be overwritten.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template<typename T>
    class overwrite_node : public graph_node, public receiver<T>, public sender<T> {
    public:
        explicit overwrite_node( graph &g );
        overwrite_node( const overwrite_node &src );
        ~overwrite_node();

        bool try_put( const T &v );
    };
} // namespace flow
} // namespace tbb
} // namespace oneapi

```

(continues on next page)

(continued from previous page)

```

    bool try_get( T &v );

    bool is_valid( );
    void clear( );
};

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The type T must meet the *DefaultConstructible* requirements from [defaultconstructible] and *CopyAssignable* requirements from [copyassignable] ISO C++ Standard sections.

This type of node buffers a single item of type T. The value is initially invalid. Gets from the node are non-destructive.

`overwrite_node` is a `graph_node`, `receiver<T>` and `sender<T>`.

`overwrite_node` has a *buffering* and *broadcast-push properties*.

`overwrite_node` allows overwriting its single item buffer.

Member functions

explicit `overwrite_node`(*graph* &g)

Constructs an object of type `overwrite_node` that belongs to the graph g with an invalid internal buffer item.

`overwrite_node`(const *overwrite_node* &src)

Constructs an object of type `overwrite_node` that belongs to the graph g with an invalid internal buffer item. The buffered value and list of successors and predecessors are not copied from `src`.

`~overwrite_node`()

Destroys the `overwrite_node`.

bool `try_put`(const T &v)

Stores v in the internal single item buffer and calls `try_put(v)` on all successors.

Returns: true

bool `try_get`(T &v)

If the internal buffer is valid, assigns the value to v.

Returns: true if v is assigned to; false, otherwise.

bool `is_valid`()

Returns: true if the buffer holds a valid value; false, otherwise.

void `clear`()

Invalidates the value held in the buffer.

Examples

The example demonstrates `overwrite_node` as a single-value storage that might be updated. Data can be accessed with direct `try_get()` call.

```
#include "oneapi/tbb/flow_graph.h"

int main() {
    const int data_limit = 20;
    int count = 0;

    oneapi::tbb::flow::graph g;

    oneapi::tbb::flow::function_node< int, int > data_set_preparation(g,
        oneapi::tbb::flow::unlimited, []( int data ) {
            printf("Prepare large data set and keep it inside node storage\n");
            return data;
        });

    oneapi::tbb::flow::overwrite_node< int > overwrite_storage(g);

    oneapi::tbb::flow::input_node< int > data_generator(g,
        [&]( oneapi::tbb::flow_control& fc ) -> int {
            if ( count < data_limit ) {
                return ++count;
            }
            fc.stop();
            return {};
        });

    oneapi::tbb::flow::function_node< int > process(g, oneapi::tbb::flow::unlimited,
        [&]( const int& data ) {
            int data_from_storage = 0;
            overwrite_storage.try_get(data_from_storage);
            printf("Data from a storage: %d\n", data_from_storage);
            printf("Data to process: %d\n", data);
        });

    oneapi::tbb::flow::make_edge(data_set_preparation, overwrite_storage);
    oneapi::tbb::flow::make_edge(data_generator, process);

    data_set_preparation.try_put(1);
    data_generator.activate();

    g.wait_for_all();

    return 0;
}
```

`overwrite_node` supports reserving `join_node` as its successor. See the example in *the example section of [write_once_node](#)*.

write_once_node

[flow_graph.write_once_node]

A node that is a buffer of a single item that cannot be overwritten.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename T >
    class write_once_node : public graph_node, public receiver<T>, public sender<T> {
    public:
        explicit write_once_node( graph &g );
        write_once_node( const write_once_node &src );
        ~write_once_node();

        bool try_put( const T &v );
        bool try_get( T &v );

        bool is_valid( );
        void clear( );
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

Requirements:

- The T type must meet the *DefaultConstructible* requirements from [defaultconstructible] and *CopyAssignable* requirements from [copyassignable] ISO C++ Standard sections.

This type of node buffers a single item of type T. The value is initially invalid. Gets from the node are non-destructive.

write_once_node is a graph_node, receiver<T> and sender<T>.

write_once_node has a *buffering* and *broadcast-push properties*.

write_once_node does not allow overwriting its single item buffer.

Member functions

explicit **write_once_node**(*graph* &g)

Constructs an object of type write_once_node that belongs to the graph g, with an invalid internal buffer item.

write_once_node(const *write_once_node* &src)

Constructs an object of type write_once_node with an invalid internal buffer item. The buffered value and list of successors is not copied from src.

~write_once_node()

Destroys the write_once_node.

bool **try_put**(const T &v)

Stores v in the internal single item buffer if it does not contain a valid value already. If a new value is set, the node broadcast it to all successors.

Returns: true for the first time after construction or a call to `clear()`; false, otherwise.

bool **try_get**(T &v)

If the internal buffer is valid, assigns the value to v.

Returns: true if v is assigned to; false, otherwise.

bool **is_valid**()

Returns: true if the buffer holds a valid value; false, otherwise.

void **clear**()

Invalidates the value held in the buffer.

Example

Usage scenario is similar to *overwrite_node* but an internal buffer can be updated only after `clear()` call. The following example shows the possibility to connect the node to a reserving `join_node`, avoiding direct calls to the `try_get()` method from the body of the successor node.

```
#include "oneapi/tbb/flow_graph.h"

typedef int data_type;

int main() {
    using namespace oneapi::tbb::flow;

    graph g;

    function_node<data_type, data_type> static_result_computer_n(
        g, serial,
        [&](const data_type& msg) {
            // compute the result using incoming message and pass it further, e.g.:
            data_type result = data_type((msg << 2 + 3) / 4);
            return result;
        });
    write_once_node<data_type> write_once_n(g); // for buffering once computed value

    buffer_node<data_type> buffer_n(g);
    join_node<tuple<data_type, data_type>, reserving> join_n(g);

    function_node<tuple<data_type, data_type>> consumer_n(
        g, unlimited,
        [&](const tuple<data_type, data_type>& arg) {
            // use the precomputed static result along with dynamic data
            data_type precomputed_result = get<0>(arg);
            data_type dynamic_data = get<1>(arg);
        });

    make_edge(static_result_computer_n, write_once_n);
    make_edge(write_once_n, input_port<0>(join_n));
    make_edge(buffer_n, input_port<1>(join_n));
}
```

(continues on next page)

(continued from previous page)

```

make_edge(join_n, consumer_n);

// do one-time calculation that will be reused many times further in the graph
static_result_computer_n.try_put(1);

for (int i = 0; i < 100; i++) {
    buffer_n.try_put(1);
}

g.wait_for_all();

return 0;
}

```

buffer_node

[flow_graph.buffer_node]

A node that is an unbounded buffer of messages. Messages are forwarded in an arbitrary order.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename T>
    class buffer_node : public graph_node, public receiver<T>, public sender<T> {
    public:
        explicit buffer_node( graph &g );
        buffer_node( const buffer_node &src );
        ~buffer_node();

        bool try_put( const T &v );
        bool try_get( T &v );
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The type T must meet the *CopyConstructible* requirements from [copyconstructible] and *CopyAssignable* requirements from [copyassignable] ISO C++ Standard sections.

buffer_node is a graph_node, receiver<T>, and sender<T>.

buffer_node has a *buffering* and *single-push properties*.

buffer_node forwards messages in an arbitrary order to a single successor in its successor set.

Member functions

explicit **buffer_node**(*graph* &g)

Constructs an empty **buffer_node** that belongs to the graph *g*.

explicit **buffer_node**(const *buffer_node* &src)

Constructs an empty **buffer_node** that belongs to the same graph *g* as *src*. Any intermediate state of *src*, including its links to predecessors and successors, is not copied.

bool **try_put**(const T &v)

Adds *v* to the set of items managed by the node, and tries forwarding it to a successor.

Returns: true

bool **try_get**(T &v)

Returns: true if an item can be removed from the node and assigned to *v*. Returns false if there is no non-reserved item currently in the node.

queue_node

[flow_graph.queue_node]

A node that forwards messages in a first-in first-out (FIFO) order.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template <typename T >
    class queue_node : public graph_node, public receiver<T>, public sender<T> {
    public:
        explicit queue_node( graph &g );
        queue_node( const queue_node &src );
        ~queue_node();

        bool try_put( const T &v );
        bool try_get( T &v );
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

Requirements:

- The type *T* must meet the *CopyConstructible* requirements from [copyconstructible] and *CopyAssignable* requirements from [copyassignable] ISO C++ Standard sections.

queue_node forwards messages in a FIFO order to a single successor in its successor set.

queue_node is a **graph_node**, **receiver** and **sender**.

queue_node has a *buffering* and *single-push properties*.

Member functions

explicit `queue_node`(*graph* &g)

Constructs an empty `queue_node` that belongs to the graph g.

`queue_node`(const *queue_node* &src)

Constructs an empty `queue_node` that belongs to the same graph g as src. Any intermediate state of src, including its links to predecessors and successors, is not copied.

bool `try_put`(const T &v)

Adds v to the set of items managed by the node, and tries forwarding the least recently added item to a successor.

Returns: true.

bool `try_get`(T &v)

Returns: true if an item can be taken from the node and assigned to v. Returns false if there is no item currently in the `queue_node` or if the node is reserved.

Example

Usage scenario is similar to *buffer_node* except that messages are passed in first-in first-out (FIFO) order.

priority_queue_node

[flow_graph.priority_queue_node]

A class template that forwards messages in a priority order.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename T, typename Compare = std::less<T>>
    class priority_queue_node : public graph_node, public receiver<T>, public sender<T> {
    public:
        explicit priority_queue_node( graph &g );
        priority_queue_node( const priority_queue_node &src );
        ~priority_queue_node();

        bool try_put( const T &v );
        bool try_get( T &v );
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

Requirements:

- The type T must meet the *CopyConstructible* requirements from [copyconstructible] and *CopyAssignable* requirements from [copyassignable] ISO C++ Standard sections.

- The type `Compare` must meet the *Compare* type requirements from [alg.sorting] ISO C++ Standard section. If `Compare` instance throws an exception, then behavior is undefined.

The next message to be forwarded has the largest priority as determined by the `Compare` template argument.

`priority_queue_node` is a `graph_node`, `receiver<T>`, and `sender<T>`.

`priority_queue_node` has a *buffering* and *single-push properties*.

Member functions

explicit `priority_queue_node`(*graph* &g)

Constructs an empty `priority_queue_node` that belongs to the graph `g`.

`priority_queue_node`(const *priority_queue_node* &src)

Constructs an empty `priority_queue_node` that belongs to the same graph `g` as `src`. Any intermediate state of `src`, including its links to predecessors and successors, is not copied.

bool `try_put`(const T &v)

Adds `v` to the `priority_queue_node` and tries forwarding to a successor the item with the largest priority among all of the items that were added to the node and have not been yet forwarded to successors.

Returns: true

bool `try_get`(T &v)

Returns: true if a message is available in the node and the node is not currently reserved. Otherwise, returns false. If the node returns true, the message with the largest priority is copied to `v`.

Example

Usage scenario is similar to *sequencer_node* except that the `priority_queue_node` provides local order, passing the message with highest priority of all stored at the moment, while *sequencer_node* enforces global order and does not allow a “smaller priority” message to pass through before all preceding messages.

sequencer_node

[`flow_graph.sequencer_node`]

A node that forwards messages in a sequence order.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename T >
    class sequencer_node : public graph_node, public receiver<T>, public sender<T> {
    public:
        template< typename Sequencer >
        sequencer_node( graph &g, const Sequencer &s );
        sequencer_node( const sequencer_node &src );

        bool try_put( const T &v );
    };
};
};
};
```

(continues on next page)

(continued from previous page)

```

    bool try_get( output_type &v );
};

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The type T must meet the *CopyConstructible* requirements from [copyconstructible] and *CopyAssignable* requirements from [copyassignable] ISO C++ Standard sections.
- The type Sequencer must meet the *Sequencer requirements*. If Sequencer instance throws an exception, behavior is undefined.

sequencer_node forwards messages in a sequence order to a single successor in its successor set.

sequencer_node is a graph_node, receiver<T> and sender<T>.

Each item that passes through a sequencer_node is ordered by its sequencer order number. These sequence order numbers range from 0 to the largest integer representable by the std::size_t type. Sequencer order number of an item is determined by passing the item to a user-provided Sequencer function object.

Note: The sequencer_node rejects duplicate sequencer numbers.

Member functions

template<typename Sequencer>

sequencer_node(graph &g, const Sequencer &s)

Constructs an empty sequencer_node that belongs to the graph g and uses s to compute sequence numbers for items.

sequencer_node(const sequencer_node &src)

Constructs an empty sequencer_node that belongs to the same graph g as src and uses a copy of the Sequencer s used to construct src. The list of predecessors, the list of successors, and the messages inside are not copied.

Caution: The new sequencer object is copy-constructed from a copy of the original sequencer object provided to src at its construction. Changes made to member variables in the src object do not affect the sequencer of the new sequencer_node.

bool **try_put**(const T &v)

Adds v to the sequencer_node and tries forwarding the next item in the sequence to a successor.

Returns: true

bool **try_get**(T &v)

Returns: true if the next item in the sequence is available in the sequencer_node. If so, it is removed from the node and assigned to v. Returns false if the next item in sequencer order is not available or if the node is reserved.

Deduction Guides

```
template <typename Body>
sequencer_node(graph&, Body) -> input_node<std::decay_t<input_t<Body>>>;
```

Where:

- `input_t` is an alias to `Body` input argument type.

Example

The example demonstrates ordering capabilities of the `sequencer_node`. While being processed in parallel, the data is passed to the successor node in the exact same order it was read.

```
#include "oneapi/tbb/flow_graph.h"

struct Message {
    int id;
    int data;
};

int main() {
    oneapi::tbb::flow::graph g;

    // Due to parallelism the node can push messages to its successors in any order
    oneapi::tbb::flow::function_node< Message, Message > process(g,
↳oneapi::tbb::flow::unlimited, [] (Message msg) -> Message {
        msg.data++;
        return msg;
    });

    oneapi::tbb::flow::sequencer_node< Message > ordering(g, [] (const Message& msg) ->
↳int {
        return msg.id;
    });

    oneapi::tbb::flow::function_node< Message > writer(g, oneapi::tbb::flow::serial, []
↳(const Message& msg) {
        printf("Message recieved with id: %d\n", msg.id);
    });

    oneapi::tbb::flow::make_edge(process, ordering);
    oneapi::tbb::flow::make_edge(ordering, writer);

    for (int i = 0; i < 100; ++i) {
        Message msg = { i, 0 };
        process.try_put(msg);
    }

    g.wait_for_all();
}
```

Service Nodes

These nodes are designed for advanced control of the message flow, such as combining messages from different paths in a graph or limiting the number of simultaneously processed messages, as well as for creating reusable custom nodes.

limiter_node

[flow_graph.limiter_node]

A node that counts and limits the number of messages that pass through it.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename T, typename DecrementType=continue_msg >
    class limiter_node : public graph_node, public receiver<T>, public sender<T> {
    public:
        limiter_node( graph &g, size_t threshold );
        limiter_node( const limiter_node &src );

        receiver<DecrementType>& decrementer();

        bool try_put( const T &v );
        bool try_get( T &v );
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

Requirements:

- T type must meet the *DefaultConstructible* requirements from [defaultconstructible] ISO C++ Standard section.
- The DecrementType type must be an integral type or `continue_msg`.

`limiter_node` is a `graph_node`, `receiver<T>`, and `sender<T>`

`limiter_node` has a *discarding* and *broadcast-push properties*.

This node does not accept new messages once the user-specified `threshold` is reached. The internal counter of broadcasts is adjusted through use of the *decrementer*, a `receiver` object embedded into the node that can be obtained by calling the `decrementer` method. The counter values are truncated to be inside the `[0, threshold]` interval.

The template parameter `DecrementType` specifies the type of the message that can be sent to the decrementer. This template parameter is defined to `continue_msg` by default. If an integral type is specified, positive values sent to the decrementer determine the value by which the internal counter of broadcasts will be decreased, while negative values determine the value by which the internal counter of broadcasts will be increased.

If `continue_msg` is used as an argument for the `DecrementType` template parameter, the `decrementer`'s port of the `limiter_node` also acquires the behavior of the `continue_node`. This behavior requires the number of messages sent to it to be equal to the number of connected predecessors before decrementing the internal counter of broadcasts by one.

When `try_put` call on the decremter results in the new value of the counter of broadcasts to be less than the threshold, the `limiter_node` tries to get a message from one of its known predecessors and forward that message to all its successors. If it cannot obtain a message from a predecessor, it decrements the counter of broadcasts.

Member functions

`limiter_node`(*graph* &g, size_t threshold)

Constructs a `limiter_node` that allows up to `threshold` items to pass through before rejecting `try_put`'s.

`limiter_node`(const *limiter_node* &src)

Constructs a `limiter_node` that has the same initial state that `src` had at its construction. The new `limiter_node` belongs to the same graph `g` as `src`, has the same `threshold`. The list of predecessors, the list of successors, and the current count of broadcasts are not copied from `src`.

receiver<DecrementType> &`decrementer`()

Obtains a reference to the embedded `receiver` object that is used for the internal counter adjustments.

bool `try_put`(const T &v)

If the broadcast count is below the threshold, `v` is broadcast to all successors.

Returns: true if `v` is broadcast; false if `v` is not broadcast because the threshold has been reached.

bool `try_get`(T &v)

Returns: false.

broadcast_node

[`flow_graph.broadcast_node`]

A node that broadcasts incoming messages to all of its successors.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename T >
    class broadcast_node :
    public graph_node, public receiver<T>, public sender<T> {
    public:
        explicit broadcast_node( graph &g );
        broadcast_node( const broadcast_node &src );

        bool try_put( const T &v );
        bool try_get( T &v );
    };

} // namespace flow
} // namespace tbb
} //namespace oneapi
```

`broadcast_node` is a `graph_node`, `receiver<T>`, and `sender<T>`.

`broadcast_node` has a *discarding* and *broadcast-push properties*.

All messages are forwarded immediately to all successors.

Member functions

explicit **broadcast_node**(*graph* &g)

Constructs an object of type `broadcast_node` that belongs to the graph `g`.

broadcast_node(const *broadcast_node* &src)

Constructs an object of type `broadcast_node` that belongs to the same graph `g` as `src`. The list of predecessors and the list of successors are not copied.

bool **try_put**(const input_type &v)

Broadcasts `v` to all successors.

Returns: always returns `true`, even if it was unable to successfully forward the message to any of its successors.

bool **try_get**(output_type &v)

Returns: `false`.

join_node

[flow_graph.join_node]

A node that creates a tuple from a set of messages received at its input ports and broadcasts the tuple to all of its successors.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {
    using tag_value = /*implementation-specific*/;

    template<typename OutputTuple, class JoinPolicy = /*implementation-defined*/>
    class join_node : public graph_node, public sender< OutputTuple > {
    public:
        using input_ports_type = /*implementation-defined*/;

        explicit join_node( graph &g );
        join_node( const join_node &src );

        input_ports_type &input_ports( );

        bool try_get( OutputTuple &v );
    };

    template<typename OutputTuple, typename K, class KHash=tbb_hash_compare<K> >
    class join_node< OutputTuple, key_matching<K,KHash> > : public graph_node, public
    ↪ sender< OutputTuple > {
    public:
        using input_ports_type = /*implementation-defined*/;

        explicit join_node( graph &g );
        join_node( const join_node &src );
    };

```

(continues on next page)

(continued from previous page)

```

template<typename B0, typename B1>
join_node( graph &g, B0 b0, B1 b1 );
template<typename B0, typename B1, typename B2>
join_node( graph &g, B0 b0, B1 b1, B2 b2 );
template<typename B0, typename B1, typename B2, typename B3>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3 );
template<typename B0, typename B1, typename B2, typename B3, typename B4>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4 );
template<typename B0, typename B1, typename B2, typename B3, typename B5>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5 );
template<typename B0, typename B1, typename B2, typename B3, typename B5, ↵
↵typename B6>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6 );
template<typename B0, typename B1, typename B2, typename B3, typename B5, ↵
↵typename B6, typename B6>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6, B7 b7 );
template<typename B0, typename B1, typename B2, typename B3, typename B5, ↵
↵typename B6, typename B7>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6, B7 b7 );
template<typename B0, typename B1, typename B2, typename B3, typename B5, ↵
↵typename B6, typename B7, typename B8>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6, B7 b7, B8 ↵
↵b8 );
template<typename B0, typename B1, typename B2, typename B3, typename B5, ↵
↵typename B6, typename B7, typename B8, typename B9>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6, B7 b7, B8 ↵
↵b8, B9 b9 );

input_ports_type &input_ports( );

bool try_get( OutputTuple &v );
};

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The type `OutputTuple` must be an instantiation of `std::tuple`. Each type that the tuple stores must meet the *DefaultConstructible* requirements from [defaultconstructible], *CopyConstructible* requirements from [copyconstructible] and *CopyAssignable* requirements from [copyassignable] ISO C++ Standard sections.
- The `JoinPolicy` type must be specified as one of *buffering policies* for `join_node`.
- The `KHash` type must meet the *HashCompare requirements*.
- The `Bi` types must meet the *JoinNodeFunctionObject requirements*.

A `join_node` is a `graph_node` and a `sender<OutputTuple>`. It contains a tuple of input ports, each of which is a `receiver<Type>` for each *Type* in `OutputTuple`. It supports multiple input receivers with distinct types and broadcasts a tuple of received messages to all of its successors. All input ports of a `join_node` must use the same buffering policy.

The behavior of a `join_node` is based on its buffering policy.

join_node Policies

[flow_graph.join_node_policies]

join_node supports three buffering policies at its input ports: `reserving`, `queueing`, and `key_matching`.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    struct reserving;
    struct queueing;
    template<typename K, class KHash=tbb_hash_compare<K> > struct key_matching;
    using tag_matching = key_matching<tag_value>;

} // namespace flow
} // namespace tbb
} // namespace oneapi
```

- `queueing` - As each input port is put to, the incoming message is added to an unbounded first-in first-out queue in the port. When there is at least one message at each input port, the `join_node` broadcasts a tuple containing the head of each queue to all successors. If at least one successor accepts the tuple, the head of each input port's queue is removed; otherwise, the messages remain in their respective input port queues.
- `reserving` - As each input port is put to, the `join_node` marks that an input may be available at that port and returns `false`. When all ports have been marked as possibly available, the `join_node` tries to reserve a message at each port from their known predecessors. If it is unable to reserve a message at a port, it unmarks that port, and releases all previously acquired reservations. If it is able to reserve a message at all ports, it broadcasts a tuple containing these messages to all successors. If at least one successor accepts the tuple, the reservations are consumed; otherwise, they are released.
- `key_matching<typename K, class KHash=tbb_hash_compare<K>>` - As each input port is put to, a user-provided function object is applied to the message to obtain its key. The message is then added to a hash table of the input port. When there is a message at each input port for a given key, the `join_node` removes all matching messages from the input ports, constructs a tuple containing the matching messages and attempts to broadcast it to all successors. If no successor accepts the tuple, it is saved and will be forwarded on a subsequent `try_get`.
- `tag_matching` - A specialization of `key_matching` that accepts keys of type `tag_value`.

The function template `input_port` simplifies the syntax for getting a reference to a specific input port.

`join_node` has a *buffering* and *broadcast-push properties*.

Member types

`input_ports_type` is an alias to a tuple of input ports.

Member functions

```
explicit join_node( graph &g );
```

Constructs an empty `join_node` that belongs to the graph `g`.

```
template<typename B0, typename B1>
join_node( graph &g, B0 b0, B1 b1 );
template<typename B0, typename B1, typename B2>
join_node( graph &g, B0 b0, B1 b1, B2 b2 );
template<typename B0, typename B1, , typename B2, typename B3>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3 );
template<typename B0, typename B1, , typename B2, typename B3, typename B4>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4 );
template<typename B0, typename B1, , typename B2, typename B3, typename B5>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5 );
template<typename B0, typename B1, , typename B2, typename B3, typename B5, typename B6>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6 );
template<typename B0, typename B1, , typename B2, typename B3, typename B5, typename B6,
↳ typename B6>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6, B7 b7 );
template<typename B0, typename B1, , typename B2, typename B3, typename B5, typename B6,
↳ typename B7>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6, B7 b7 );
template<typename B0, typename B1, , typename B2, typename B3, typename B5, typename B6,
↳ typename B7, typename B8>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6, B7 b7, B8 b8 );
template<typename B0, typename B1, , typename B2, typename B3, typename B5, typename B6,
↳ typename B7, typename B8, typename B9>
join_node( graph &g, B0 b0, B1 b1, B2 b2, B3 b3, B4 b4, B5 b5, B6 b6, B7 b7, B8 b8, B9
↳ b9 );
```

A constructor only available in the `key_matching` specialization of `join_node`.

Creates a `join_node` that uses the function objects `b0`, `b1`, ... , `bN` to determine the tags for the input ports 0 through `N`.

Caution: Function objects passed to the `join_node` constructor must not throw. They are called in parallel, and should be pure, take minimal time, and be non-blocking.

```
join_node( const join_node &src )
```

Creates a `join_node` that has the same initial state that `src` had at its construction. The list of predecessors, messages in the input ports, and successors are not copied.

```
input_ports_type &input_ports( )
```

Returns: a `std::tuple` of receivers. Each element inherits values from `receiver<T>`, where T is the type of message expected at that input. Each tuple element can be used like any other `receiver<T>`. The behavior of the ports is based on the selected `join_node` policy.

```
bool try_get( output_type &v )
```

Attempts to generate a tuple based on the buffering policy of the `join_node`.

If it can successfully generate a tuple, it copies it to `v` and returns `true`. Otherwise, it returns `false`.

Non-Member Types

```
using tag_value = /*implementation-specific*/;
```

`tag_value` is an unsigned integral type for defining the `tag_matching` policy.

Deduction Guides

```
template <typename Body, typename... Bodies>
join_node(graph&, Body, Bodies...)
    ->join_node<std::tuple<std::decay_t<input_t<Body>>, std::decay_t<input_t<Bodies>>...>
    ↔, key_matching<output_t<Body>>>;
```

Where:

- `input_t` is an alias to the input argument type of the passed function object.
- `output_t` is an alias to the return type of the passed function object.

split_node

[flow_graph.split_node]

A `split_node` sends each element of the incoming `std::tuple` to the output port that matches the element index in the incoming tuple.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template < typename TupleType >
    class split_node : public graph_node, public receiver<TupleType> {
    public:
        explicit split_node( graph &g );
        split_node( const split_node &other );
        ~split_node();

        bool try_put( const TupleType &v );
```

(continues on next page)

(continued from previous page)

```

    using output_ports_type = /*implementation-defined*/ ;
    output_ports_type& output_ports();
};

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The type TupleType must be an instantiation of `std::tuple`.

`split_node` is a receiver<TupleType> and has a tuple of sender output ports. Each of output ports is specified by corresponding tuple element type. This node receives a tuple at its single input port and generates a message from each element of the tuple, passing each to the corresponding output port.

`split_node` has a *discarding* and *broadcast-push properties*.

`split_node` has unlimited concurrency, and behaves as a `broadcast_node` with multiple output ports.

Member functions

explicit `split_node`(*graph* &g)

Constructs a `split_node` registered with graph g.

`split_node`(const *split_node* &other)

Constructs a `split_node` that has the same initial state that `other` had when it was constructed. The `split_node` that is constructed has a reference to the same `graph` object as `other`. The predecessors and successors of `other` are not copied.

`~split_node`()

Destructor

bool `try_put`(const TupleType &v)

Broadcasts each element of the incoming tuple to the nodes connected to the `split_node` output ports. The element at index `i` of `v` will be broadcast through the `i`th output port.

Returns: true

output_ports_type &`output_ports`()

Returns: a `std::tuple` of output ports.

indexer_node

[`flow_graph.indexer_node`]

`indexer_node` broadcasts messages received at input ports to all of its successors. The messages are broadcast individually as they are received at each port. The output is a *tagged message* that contains a tag and a value; the tag identifies the input port on which the message was received.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {

```

(continues on next page)

(continued from previous page)

```

namespace flow {

    template<typename T0, typename... TN>
    class indexer_node : public graph_node, public sender</*implementation_defined*/> {
    public:
        indexer_node(graph &g);
        indexer_node(const indexer_node &src);

        using input_ports_type = /*implementation_defined*/;
        input_ports_type &input_ports();

        using output_type = tagged_msg<size_t, T0, TN...>;
        bool try_get( output_type &v );
    };

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The T0 type and all types in TN template parameter pack must meet the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard section.

An `indexer_node` is a `graph_node` and `sender<tagged_msg<size_t, T0, TN...>>`. It contains a tuple of input ports, each of which is a receiver specified by corresponding input template parameter pack element. It supports multiple input receivers with distinct types and broadcasts each received message to all of its successors. Unlike a `join_node`, each message is broadcast individually to all successors of the `indexer_node` as it arrives at an input port. Before broadcasting, a message is tagged with the index of the port on which the message arrived.

`indexer_node` has a *discarding* and *broadcast-push properties*.

The function template `input_port` simplifies the syntax for getting a reference to a specific input port.

Member types

- `input_ports_type` is an alias to a `std::tuple` of input ports.
- `output_type` is an alias to the message of type `tagged_msg`, which is sent to successors.

Member functions

`indexer_node`(*graph* &g)

Constructs an `indexer_node` that belongs to the graph g.

`indexer_node`(const *indexer_node* &src)

Constructs an `indexer_node`. The list of predecessors, messages in the input ports, and successors are not copied.

`input_ports_type` &`input_ports`()

Returns: A `std::tuple` of receivers. Each element inherits from `receiver<T>` where T is the type of message expected at that input. Each tuple element can be used like any other `receiver<T>`.

bool `try_get`(`output_type` &v)

An `indexer_node` contains no buffering and therefore does not support gets.

Returns: false.

See also:

- *input_port function template*
- *tagged_msg template class*

composite_node

[flow_graph.composite_node]

A node that encapsulates a collection of other nodes as a first class graph node.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template< typename InputTuple, typename OutputTuple > class composite_node;

    // composite_node with both input ports and output ports
    template< typename... InputTypes, typename... OutputTypes>
    class composite_node <std::tuple<InputTypes...>, std::tuple<OutputTypes...> > :
    ↪ public graph_node {
    public:
        typedef std::tuple< receiver<InputTypes>&... > input_ports_type;
        typedef std::tuple< sender<OutputTypes>&... > output_ports_type;

        composite_node( graph &g );
        virtual ~composite_node();

        void set_external_ports(input_ports_type&& input_ports_tuple, output_ports_type&&
    ↪ output_ports_tuple);
        input_ports_type& input_ports();
        output_ports_type& output_ports();
    };

    // composite_node with only input ports
    template< typename... InputTypes>
    class composite_node <std::tuple<InputTypes...>, std::tuple<> > : public graph_node{
    public:
        typedef std::tuple< receiver<InputTypes>&... > input_ports_type;

        composite_node( graph &g );
        virtual ~composite_node();

        void set_external_ports(input_ports_type&& input_ports_tuple);
        input_ports_type& input_ports();
    };

    // composite_nodes with only output_ports
    template<typename... OutputTypes>
```

(continues on next page)

(continued from previous page)

```

class composite_node <std::tuple<>, std::tuple<OutputTypes...> > : public graph_node{
public:
    typedef std::tuple< sender<OutputTypes>&... > output_ports_type;

    composite_node( graph &g );
    virtual ~composite_node();

    void set_external_ports(output_ports_type&& output_ports_tuple);
    output_ports_type& output_ports();
};

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

- The InputTuple and OutputTuple must be instantiations of std::tuple.

composite_node is a graph_node, receiver<T>, and sender<T>.

The composite_node can package any number of other nodes. It maintains input and output port references to nodes in the package that border the composite_node. This allows the references to be used to make edges to other nodes outside of the composite_node. The InputTuple is a tuple of input types. The composite_node has an input port for each type in InputTuple. Likewise, the OutputTuple is a tuple of output types. The composite_node has an output port for each type in OutputTuple.

The composite_node is a multi-port node with three specializations.

- **A multi-port node with multi-input ports and multi-output ports:** This specialization has a tuple of input ports, each of which is a receiver of a type in InputTuple. Each input port is a reference to a port of a node that the composite_node encapsulates. Similarly, this specialization also has a tuple of output ports, each of which is a sender of a type in OutputTuple. Each output port is a reference to a port of a node that the composite_node encapsulates.
- **A multi-port node with only input ports and no output ports:** This specialization only has a tuple of input ports.
- **A multi-port node with only output ports and no input ports:** This specialization only has a tuple of output ports.

The function template *input_port* can be used to get a reference to a specific input port and the function template *output_port* can be used to get a reference to a specific output port.

Construction of a composite_node is done in two stages:

- Defining the composite_node with specification of InputTuple and OutputTuple.
- Making aliases from the encapsulated nodes that border the composite_node to the input and output ports of the composite_node. This step is mandatory as without it the composite_node input and output ports are not bound to any actual nodes. Making the aliases is achieved by calling the method set_external_ports.

The composite_node does not meet the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard section.

Member functions

composite_node(*graph* &g)

Constructs a `composite_node` that belongs to the graph `g`.

void **set_external_ports**(input_ports_type &&input_ports_tuple, output_ports_type &&output_ports_tuple)

Creates input and output ports of the `composite_node` as aliases to the ports referenced by `input_ports_tuple` and `output_ports_tuple`, respectively. That is, a port referenced at position `N` in `input_ports_tuple` is mapped as the `N`th input port of the `composite_node`, similarly for output ports.

input_ports_type &**input_ports**()

Returns: A `std::tuple` of receivers. Each element is a reference to the actual node or input port that was aliased to that position in `set_external_ports()`.

Caution: Calling `input_ports()` without a prior call to `set_external_ports()` results in undefined behavior.

output_ports_type &**output_ports**()

Returns: A `std::tuple` of senders. Each element is a reference to the actual node or output port that was aliased to that position in `set_external_ports()`.

Caution: Calling `output_ports()` without a prior call to `set_external_ports()` results in undefined behavior.

Ports and Edges

Flow Graph provides an API to manage connections between the nodes. For nodes that have more than one input or output ports (for example, `join_node`), making a connection requires to specify a certain port by using special helper functions.

input_port

[`flow_graph.input_port`]

A template function that returns a reference to a specific input port of a given `join_node`, `indexer_node` or `composite_node`.

```
// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template<size_t N, typename NodeType>
```

(continues on next page)

(continued from previous page)

```

    /*implementation-defined*/& input_port(NodeType &n);
} // namespace flow
} // namespace tbb
} // namespace oneapi

```

See also:

- *join_node* template class
- *indexer_node* template class
- *composite_node* template class

output_port

[flow_graph.output_port]

A template function that returns a reference to a specific output port of a given `split_node`, `indexer_node`, or `composite_node`.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    template<size_t N, typename NodeType>
        /*implementation-defined*/& output_port(NodeType &n);

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

See also:

- *split_node* Template Class
- *multifunction_node* Template Class
- *composite_node* Template Class

make_edge

[flow_graph.make_edge]

A function template for building edges between nodes.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

```

(continues on next page)

(continued from previous page)

```

template<typename Message>
inline void make_edge( sender<Message> &p, receiver<Message> &s );

template< typename MultiOutputNode, typename MultiInputNode >
inline void make_edge( MultiOutputNode& output, MultiInputNode& input );

template<typename MultiOutputNode, typename Message>
inline void make_edge( MultiOutputNode& output, receiver<Message> input );

template<typename Message, typename MultiInputNode>
inline void make_edge( sender<Message> output, MultiInputNode& input );

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The *MultiOutputNode* type must have a valid `MultiOutputNode::output_ports_type` qualified-id that denotes a type.
- The *MultiInputNode* type must have a valid `MultiInputNode::input_ports_type` qualified-id that denotes a type.

The common form of `make_edge(sender, receiver)` creates an edge between provided sender and receiver instances.

Overloads that accept a *MultiOutputNode* type instance make an edge from port 0 of a multi-output predecessor.

Overloads that accept a *MultiInputNode* type instance make an edge to port 0 of a multi-input successor.

remove_edge

[flow_graph.remove_edge]

A function template for building edges between nodes.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

template<typename Message>
inline void remove_edge( sender<Message> &p, receiver<Message> &s );

template< typename MultiOutputNode, typename MultiInputNode >
inline void remove_edge( MultiOutputNode& output, MultiInputNode& input );

template<typename MultiOutputNode, typename Message>
inline void remove_edge( MultiOutputNode& output, receiver<Message> input );

template<typename Message, typename MultiInputNode>
inline void remove_edge( sender<Message> output, MultiInputNode& input );

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

(continues on next page)

(continued from previous page)

```

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- The *MultiOutputNode* type must have a valid `MultiOutputNode::output_ports_type` qualified-id that denotes a type.
- The *MultiInputNode* type must have a valid `MultiInputNode::input_ports_type` qualified-id that denotes a type.

The common form of `remove_edge(sender, receiver)` creates an edge between provided `sender` and `receiver` instances.

Overloads that accept a *MultiOutputNode* type instance remove an edge from port 0 of a multi-output predecessor.

Overloads that accept a *MultiInputNode* type instance remove an edge to port 0 of a multi-input successor.

Special Messages Types

Flow Graph supports a set of specific message types.

continue_msg

[flow_graph.continue_msg]

An empty class that represents a continue message. An object of this class is used to indicate that the sender has completed.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {
namespace flow {

    class continue_msg {};

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

tagged_msg

[flow_graph.tagged_msg]

A class template composed of a tag and a message. The message is a value that can be one of several defined types.

```

// Defined in header <oneapi/tbb/flow_graph.h>

namespace oneapi {
namespace tbb {

```

(continues on next page)

(continued from previous page)

```

namespace flow {

    template<typename TagType, typename... TN>
    class tagged_msg {
    public:
        template<typename T, typename R>
        tagged_msg(T const &index, R const &val);

        TagType tag() const;

        template<typename V>
        const V& cast_to() const;

        template<typename V>
        bool is_a() const;

    };

} // namespace flow
} // namespace tbb
} // namespace oneapi

```

Requirements:

- All types in TN template parameter pack must meet the *CopyConstructible* requirements from [copyconstructible] ISO C++ Standard section.
- The type *TagType* must be an integral unsigned type.

The `tagged_msg` class template is intended for messages whose type is determined at runtime. A message of one of the types TN is tagged with a tag of type `TagType`. The tag then can serve to identify the message. In the flow graph, `tagged_msg` is used as the output of `indexer_node`.

Member functions

```

template<typename T, typename R>
tagged_msg(T const &index, R const &value)

```

Requirements:

- The type *R* must be the same as one of the TN types.
- The type *T* must be acceptable as a `TagType` constructor parameter.

Constructs a `tagged_msg` with tag `index` and value `val`.

```

TagType tag() const

```

Returns the current tag.

```

template<typename V>
const V &cast_to() const

```

Requirements:

- The type *V* must be the same as one of the TN types.

Returns the value stored in `tagged_msg`. If the value is not of type *V*, the `std::runtime_error` exception is thrown.

```
template<typename V>
bool is_a() const
```

Requirements:

- The type V must be the same as one of the TN types.

Returns true if V is the type of the value held by the `tagged_msg`. Returns false, otherwise.

Non-member functions

```
template<typename V, typename T>
const V& cast_to(T const &t) {
    return t.cast_to<V>();
}

template<typename V, typename T>
bool is_a(T const &t);
```

Requirements:

- The type T must be an instantiated `tagged_msg` class template.
- The type V must be the same as one of the corresponding template arguments for `tagged_msg`.

The free-standing template functions `cast_to` and `is_a` applied to a `tagged_msg` object are equivalent to the calls of the corresponding methods of that object.

- *indexer_node class template*

Examples

Dependency Flow Graph Example

In the following example, five computations A-E are set up with the partial ordering shown below in “A simple dependency graph.”. For each edge in the flow graph, the node at the tail of the edge must complete its execution before the node at the head may begin.

```
#include <stdio>
#include "oneapi/tbb/flow_graph.h"

using namespace oneapi::tbb::flow;

struct body {
    std::string my_name;
    body(const char *name) : my_name(name) {}
    void operator()(continue_msg) const {
        printf("%s\n", my_name.c_str());
    }
};

int main() {
    graph g;
```

(continues on next page)

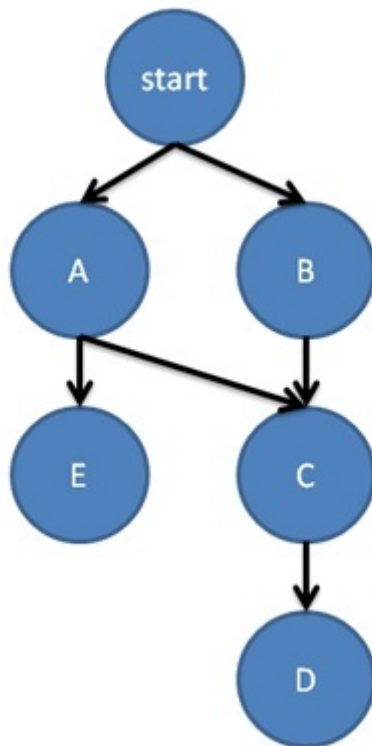

Fig. 2: A simple dependency graph.

(continued from previous page)

```

broadcast_node< continue_msg > start(g);
continue_node<continue_msg> a(g, body("A"));
continue_node<continue_msg> b(g, body("B"));
continue_node<continue_msg> c(g, body("C"));
continue_node<continue_msg> d(g, body("D"));
continue_node<continue_msg> e(g, body("E"));

make_edge(start, a);
make_edge(start, b);
make_edge(a, c);
make_edge(b, c);
make_edge(c, d);
make_edge(a, e);

for (int i = 0; i < 3; ++i) {
    start.try_put(continue_msg());
    g.wait_for_all();
}

return 0;
}

```

In this example, nodes A-E print out their names. All of these nodes are therefore able to use `struct body` to construct their body objects.

In function `main`, the flow graph is set up once and then run three times. All of the nodes in this example pass around `continue_msg` objects. This type is used to communicate that a node has completed execution.

The first line in function `main` instantiates a `graph` object `g`. On the next line, a `broadcast_node` named `start` is created. Anything passed to this node will be broadcast to all of its successors. The node `start` is used in the `for` loop at the bottom of `main` to launch the execution of the rest of the flow graph.

In the example, five `continue_node` objects are created, named a - e. Each node is constructed with a reference to graph `g` and the function object to invoke when it runs. The successor / predecessor relationships are set up by the `make_edge` calls that follow the declaration of the nodes.

After the nodes and edges are set up, the `try_put` in each iteration of the `for` loop results in a broadcast of a `continue_msg` to both a and b. Both a and b are waiting for a single `continue_msg`, since they both have only a single predecessor, `start`.

When they receive the message from `start`, they execute their body objects. When complete, each of them forwards a message to a successor, and so on. The graph uses tasks to execute the node bodies as well as to forward messages between the nodes, allowing computation to execute concurrently when possible.

- [*continue_msg class*](#)
- [*continue_node class*](#)

Message Flow Graph Example

This example calculates the sum $x*x + x*x*x$ for all $x = 1$ to 10 . The layout of this example is shown in the figure below.

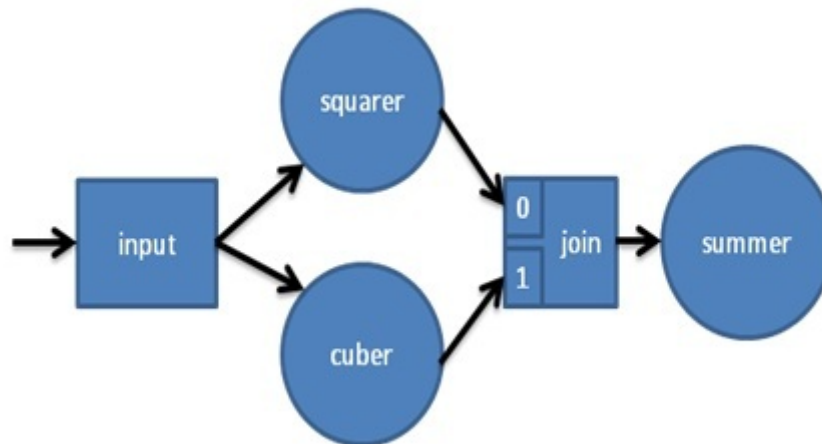

Fig. 3: A simple message flow graph.

Each value enters through the `broadcast_node<int>` `input`. This node broadcasts the value to both `squarer` and `cuber`, which calculate $x*x$ and $x*x*x$, respectively. The output of each of these nodes is put to one of `join`'s ports. A tuple containing both values is created by `join_node<std::tuple<int,int>>` `join` and forwarded to `summer`, which adds both values to the running total. Both `squarer` and `cuber` allow unlimited concurrency, that is they each may process multiple values simultaneously. The final `summer`, which updates a shared total, is only allowed to process a single incoming tuple at a time, eliminating the need for a lock around the shared value.

```

#include <cstdio>
#include "oneapi/tbb/flow_graph.h"

using namespace oneapi::tbb::flow;

struct square {
    int operator()(int v) { return v*v; }
};

struct cube {
    int operator()(int v) { return v*v*v; }
};

class sum {
    int &my_sum;
public:
    sum( int &s ) : my_sum(s) {}
    int operator()( std::tuple<int, int> v ) {
        my_sum += get<0>(v) + get<1>(v);
        return my_sum;
    }
};

```

(continues on next page)

(continued from previous page)

```

int main() {
    int result = 0;

    graph g;
    broadcast_node<int> input(g);
    function_node<int,int> squarer( g, unlimited, square() );
    function_node<int,int> cuber( g, unlimited, cube() );
    join_node<std::tuple<int,int>, queueing> join( g );
    function_node<std::tuple<int,int>,int>
        summer( g, serial, sum(result) );

    make_edge( input, squarer );
    make_edge( input, cuber );
    make_edge( squarer, get<0>( join.input_ports() ) );
    make_edge( cuber, get<1>( join.input_ports() ) );
    make_edge( join, summer );

    for (int i = 1; i <= 10; ++i)
        input.try_put(i);
    g.wait_for_all();

    printf("Final result is %d\n", result);
    return 0;
}

```

In the example code above, the classes `square`, `cube`, and `sum` define the three user-defined operations. Each class is used to create a `function_node`.

In function `main`, the flow graph is set up and then the values 1-10 are put into the node `input`. All the nodes in this example pass around values of type `int`. The nodes used in this example are all class templates and therefore can be used with any type that supports copy construction, including pointers and objects.

9.2.4 Task Scheduler

[scheduler]

oneAPI Threading Building Blocks (oneTBB) provides a task scheduler, which is the engine that drives the algorithm templates and task groups. The exact tasking API depends on the implementation.

The tasks are quanta of computation. The scheduler implements worker thread pool and maps tasks onto these threads. The mapping is non-preemptive. Once a thread starts running a task, the task is bound to that thread until completion. During that time, the thread services other tasks only when it waits for completion of nested parallel constructs, as described below. While waiting, either user or worker thread may run any available task, including unrelated tasks created by this or other threads.

The task scheduler is intended for parallelizing computationally intensive work. Because task objects are not scheduled preemptively, they should generally avoid making calls that might block a thread for long periods during which the thread cannot service other tasks.

Caution: There is no guarantee that *potentially* parallel tasks *actually* execute in parallel, because the scheduler adjusts actual parallelism to fit available worker threads. For example, given a single worker thread, the scheduler

creates no actual parallelism. For example, it is generally unsafe to use tasks in a producer consumer relationship, because there is no guarantee that the consumer runs at all while the producer is running.

Scheduling controls

task_group_context

[scheduler.task_group_context]

`task_group_context` represents a set of properties used by task scheduler for execution of the associated tasks. Each task is associated with only one `task_group_context` object.

The `task_group_context` objects form a forest of trees. Each tree's root is a `task_group_context` constructed as isolated.

`task_group_context` is cancelled explicitly by the user request, or implicitly when an exception is thrown out of an associated task. Canceling `task_group_context` causes the entire subtree rooted at it to be cancelled.

The `task_group_context` carries floating point settings inherited from the parent `task_group_context` object or captured with a dedicated interface.

```
// Defined in header <oneapi/tbb/task_group.h>

namespace oneapi {
namespace tbb {

    class task_group_context {
    public:
        enum kind_t {
            isolated = /* implementation-defined */,
            bound = /* implementation-defined */
        };
        enum traits_type {
            fp_settings = /* implementation-defined */,
            default_traits = 0
        };

        task_group_context( kind_t relation_with_parent = bound,
                           uintptr_t traits = default_traits );
        ~task_group_context();

        void reset();
        bool cancel_group_execution();
        bool is_group_execution_cancelled() const;
        void capture_fp_settings();
        uintptr_t traits() const;
    };

} // namespace tbb;
} // namespace oneapi
```

Member types and constants

enum `kind_t::isolated`

When passed to the specific constructor, the created `task_group_context` object has no parent.

enum `kind_t::bound`

When passed to the specific constructor, the created `task_group_context` object becomes a child of the innermost running task's group when the first task associated to the `task_group_context` is passed to the task scheduler. If there is no innermost running task on the current thread, the `task_group_context` becomes `isolated`.

enum `traits_type::fp_settings`

When passed to the specific constructor, the flag forces the context to capture floating-point settings from the current thread.

Member functions

`task_group_context`(`kind_t` `relation_to_parent` = `bound`, `uintptr_t` `traits` = `default_traits`)

Constructs an empty `task_group_context`.

`~task_group_context`()

Destroys an empty `task_group_context`. The behavior is undefined if there are still extant tasks associated with this `task_group_context`.

bool `cancel_group_execution`()

Requests that tasks associated with this `task_group_context` are not executed.

Returns `false` if this `task_group_context` is already cancelled; `true`, otherwise. If concurrently called by multiple threads, exactly one call returns `true` and the rest return `false`.

bool `is_group_execution_cancelled`() const

Returns `true` if this `task_group_context` has received the cancellation request.

void `reset`()

Reinitializes this `task_group_context` to the uncancelled state.

Caution: This method is only safe to call once all tasks associated with the group's subordinate groups have completed. This method must not be invoked concurrently by multiple threads.

void `capture_fp_settings`()

Captures floating-point settings from the current thread.

Caution: This method is only safe to call once all tasks associated with the group's subordinate groups have completed. This method must not be invoked concurrently by multiple threads.

`uintptr_t` `traits`() const

Returns traits of this `task_group_context`.

global_control

[scheduler.global_control]

Use this class to control certain settings or behavior of the oneTBB dynamic library.

An object of class `global_control`, or a “control variable”, affects one of several behavioral aspects, or parameters, of TBB. The `global_control` class is primarily intended for use at the application level, to control the whole application behavior.

The current set of parameters that you can modify is defined by the `global_control::parameter` enumeration. The parameter and the value it should take are specified as arguments to the constructor of a control variable. The impact of the control variable ends when its lifetime is complete.

Control variables can be created in different threads, and may have nested or overlapping scopes. However, at any point in time each controlled parameter has a single active value that applies to the whole process. This value is selected from all currently existing control variables by applying a parameter-specific selection rule.

```
// Defined in header <oneapi/tbb/global_control.h>

namespace oneapi {
namespace tbb {
    class global_control {
    public:
        enum parameter {
            max_allowed_parallelism,
            thread_stack_size,
            terminate_on_exception
        };

        global_control(parameter p, size_t value);
        ~global_control();

        static size_t active_value(parameter param);
    };
} // namespace tbb
} // namespace oneapi
```

Member types and constants

enum `parameter::max_allowed_parallelism`

Selection rule: minimum

Limits total number of worker threads that can be active in the task scheduler to `parameter_value - 1`.

Note: With `max_allowed_parallelism` set to 1, `global_control` enforces serial execution of all tasks by the application thread(s), that is, the task scheduler does not allow worker threads to run. There is one exception: if some work is submitted for execution via `task_arena::enqueue`, a single worker thread will still run ignoring the `max_allowed_parallelism` restriction.

enum `parameter::thread_stack_size`

Selection rule: maximum

Set stack size for working threads created by the library.

enum parameter::**terminate_on_exception**

Selection rule: logical disjunction

Setting the parameter to 1 causes termination in any condition that would throw or rethrow an exception. If set to 0 (default), the parameter does not affect the implementation behavior.

Member functions

global_control(parameter param, size_t value)

Constructs a `global_control` object with a specified control parameter and its value.

~global_control()

Destructs a control variable object and ends its impact.

static size_t **active_value**(parameter param)

Returns the currently active value of the setting defined by `param`.

- [task_arena](#)

Resumable tasks

[scheduler.resumable_tasks]

Functions to suspend task execution at a specific point and signal to resume it later.

```
// Defined in header <oneapi/tbb/task.h>
using oneapi::tbb::task::suspend_point = /* implementation-defined */;
template < typename Func > void oneapi::tbb::task::suspend( Func );
void oneapi::tbb::task::resume( oneapi::tbb::task::suspend_point );
```

Requirements:

- The `Func` type must meet the *SuspendFunc requirements*.

The `oneapi::tbb::task::suspend` function called within a running task suspends execution of the task and switches the thread to participate in other oneTBB parallel work. This function accepts a user callable object with the current execution context `oneapi::tbb::task::suspend_point` as an argument. The user-specified callable object is executed by the calling thread.

The `oneapi::tbb::task::suspend_point` context tag must be passed to the `oneapi::tbb::task::resume` function to trigger a program execution at the suspended point. The `oneapi::tbb::task::resume` function can be called at any point of an application, even on a separate thread. In this regard, this function acts as a signal for the task scheduler.

Note: There are no guarantees that the same thread that called `oneapi::tbb::task::suspend` continues execution after the suspended point. However, these guarantees are provided for the outermost blocking oneTBB calls (such as `oneapi::tbb::parallel_for` and `oneapi::tbb::flow::graph::wait_for_all`) and `oneapi::tbb::task_arena::execute` calls.

Example

```
// Parallel computation region
oneapi::tbb::parallel_for(0, N, [&](int) {
    // Suspend the current task execution and capture the context
    oneapi::tbb::task::suspend([&] (oneapi::tbb::task::suspend_point tag) {
        // Dedicated user-managed activity that processes async requests.
        async_activity.submit(tag); // could be OpenCL/IO/Database/Network etc.
    }); // execution will be resumed after this function
});
```

```
// Dedicated user-managed activity:

// Signal to resume execution of the task referenced by the oneapi::tbb::task::suspend_
↪point
// from a dedicated user-managed activity
oneapi::tbb::task::resume(tag);
```

task_scheduler_handle

[scheduler.task_scheduler_handle]

The `oneapi::tbb::task_scheduler_handle` class and the `oneapi::tbb::finalize` function allow user to wait for completion of worker threads.

When the `oneapi::tbb::finalize` function is called with an `oneapi::tbb::task_scheduler_handle` instance, it blocks the calling thread until the completion of all worker threads that were implicitly created by the library.

```
// Defined in header <oneapi/tbb/global_control.h>

namespace oneapi {
    namespace tbb {

        class task_scheduler_handle {
        public:
            task_scheduler_handle() = default;
            task_scheduler_handle(oneapi::tbb::attach);
            ~task_scheduler_handle();

            task_scheduler_handle(const task_scheduler_handle& other) = delete;
            task_scheduler_handle(task_scheduler_handle&& other) noexcept;
            task_scheduler_handle& operator=(const task_scheduler_handle& other) =
↪delete;
            task_scheduler_handle& operator=(task_scheduler_handle&& other) noexcept;

            explicit operator bool() const noexcept;

            void release();
        };

        void finalize(task_scheduler_handle& handle);
        bool finalize(task_scheduler_handle& handle, const std::nothrow_t&) noexcept;
```

(continues on next page)

(continued from previous page)

```

    } // namespace tbb
} // namespace oneapi

```

Member Functions

`task_scheduler_handle()`

Effects: Creates an empty instance of the `task_scheduler_handle` class that does not contain any references to the task scheduler.

`task_scheduler_handle(oneapi::tbb::attach)`

Effects: Creates an instance of the `task_scheduler_handle` class that holds a reference to the task scheduler preventing its premature destruction.

`~task_scheduler_handle()`

Effects: Destroys an instance of the `task_scheduler_handle` class. If not empty, releases a reference to the task scheduler and deactivates an instance of the `task_scheduler_handle` class.

`task_scheduler_handle(task_scheduler_handle &&other) noexcept`

Effects: Creates an instance of the `task_scheduler_handle` class that references the task scheduler referenced by `other`. In turn, `other` releases its reference to the task scheduler.

`task_scheduler_handle &operator=(task_scheduler_handle &&other) noexcept`

Effects: If not empty, releases a reference to the task scheduler referenced by `this`. Adds a reference to the task scheduler referenced by `other`. In turn, `other` releases its reference to the task scheduler. **Returns:** A reference to `*this`.

`explicit operator bool() const noexcept`

Returns: `true` if `this` is not empty and refers to some task scheduler; `false` otherwise.

`void release()`

Effects: If not empty, releases a reference to the task scheduler and deactivates an instance of the `task_scheduler_handle` class; otherwise, does nothing. Non-blocking method.

Non-member Functions

`void finalize(task_scheduler_handle &handle)`

Effects: If `handle` is not empty, blocks the program execution until all worker threads have been completed; otherwise, does nothing. Throws the `oneapi::tbb::unsafe_wait` exception if it is not safe to wait for the completion of the worker threads.

The following conditions should be met for finalization to succeed:

- No active, not yet terminated, instances of `task_arena` class exist in the whole program.

- `task_scheduler_handle::release` is called for each other active instance of `task_scheduler_handle` class, possibly by different application threads.

Under these conditions, it is guaranteed that at least one `finalize` call succeeds, at which point all worker threads have been completed. If calls are performed simultaneously, more than one call might succeed.

Note: If user knows how many active `task_scheduler_handle` instances exist in the program, it is necessary to release all but the last one, then call `finalize` for the last instance.

Caution: The method always fails if called within a task, a parallel algorithm, or a flow graph node.

bool **finalize**(*task_scheduler_handle* &handle, const std::nothrow_t&) noexcept

Effects: If `handle` is not empty, blocks the program execution until all worker threads have been completed; otherwise, does nothing. The behavior is the same as `finalize(handle)` however, `false` is returned instead of exception or `true` if no exception.

Examples

```
#include <oneapi/tbb/global_control.h>
#include <oneapi/tbb/parallel_for.h>

#include <iostream>

int main() {
    oneapi::tbb::task_scheduler_handle handle;

    handle = oneapi::tbb::task_scheduler_handle{oneapi::tbb::attach{}};

    // Do some parallel work here, e.g.
    oneapi::tbb::parallel_for(0, 10000, [](int){});
    try {
        oneapi::tbb::finalize(handle);
        // oneTBB worker threads are terminated at this point.
    } catch (const oneapi::tbb::unsafe_wait&) {
        std::cerr << "Failed to terminate the worker threads." << std::endl;
    }
    return 0;
}
```

- [attach](#)

Task Group

task_group

[scheduler.task_group]

A `task_group` represents concurrent execution of a group of tasks. Tasks can be dynamically added to the group while it is executing.

```
// Defined in header <oneapi/tbb/task_group.h>

namespace oneapi {
namespace tbb {

    class task_group {
    public:
        task_group();
        task_group(task_group_context& context);

        ~task_group();

        template<typename Func>
        void run(Func&& f);

        template<typename Func>
        task_handle defer(Func&& f);

        void run(task_handle&& h);

        template<typename Func>
        task_group_status run_and_wait(const Func& f);

        task_group_status run_and_wait(task_handle&& h);

        task_group_status wait();
        void cancel();
    };

    bool is_current_task_group_canceling();
} // namespace tbb
} // namespace oneapi
```

Member functions

`task_group()`

Constructs an empty `task_group`.

`task_group(task_group_context &context)`

Constructs an empty `task_group`. All tasks added into the `task_group` are associated with the context.

`~task_group()`

Destroys the `task_group`.

Requires: Method `wait` must be called before destroying a `task_group`, otherwise, the destructor throws an exception.

```
template<typename F>
```

```
task_handle defer(F &&f)
```

Creates a deferred task to compute `f()` and returns `task_handle` pointing to it.

The task is not scheduled for the execution until it is explicitly requested, for example, with the `task_group::run` method. However, the task is still added into the `task_group`, thus the `task_group::wait` method waits until the `task_handle` is either scheduled or destroyed.

The `F` type must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard.

Returns: `task_handle` object pointing to a task to compute `f()`.

```
template<typename Func>
```

```
void run(Func &&f)
```

Adds a task to compute `f()` and returns immediately. The `Func` type must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard.

```
void run(task_handle &&h)
```

Schedules the task object pointed by the `h` for the execution.

Note:

The failure to satisfy the following conditions leads to undefined behavior:

- `h` is not empty.
 - `*this` is the same `task_group` that `h` is created with.
-

```
template<typename Func>
```

```
task_group_status run_and_wait(const Func &f)
```

Equivalent to `{run(f); return wait();}`. The `Func` type must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard.

Returns: The status of `task_group`. See *task_group_status*.

```
task_group_status wait()
```

Waits for all tasks in the group to complete or be cancelled.

Returns: The status of `task_group`. See *task_group_status*.

```
void cancel()
```

Cancels all tasks in this `task_group`.

Non-member functions

```
bool is_current_task_group_canceling()
```

Returns true if an innermost `task_group` executing on this thread is cancelling its tasks.

task_group_status

[scheduler.task_group_status]

A task_group_status type represents the status of a task_group.

```

namespace oneapi {
namespace tbb {
    enum task_group_status {
        not_complete,
        complete,
        canceled
    };
} // namespace tbb
} // namespace oneapi

```

Member constants

not_complete

Not cancelled and not all tasks in a group have completed.

complete

Not cancelled and all tasks in a group have completed.

canceled

Task group received cancellation request.

task_handle

[scheduler.task_handle]

An instance of task_handle type owns a deferred task object.

```

namespace oneapi {
namespace tbb {

    class task_handle {
    public:
        task_handle();
        task_handle(task_handle&& src);

        ~task_handle();

        task_handle& operator=(task_handle&& src);

        explicit operator bool() const noexcept;
    };

    bool operator==(task_handle const& h, std::nullptr_t) noexcept;
    bool operator==(std::nullptr_t, task_handle const& h) noexcept;

    bool operator!=(task_handle const& h, std::nullptr_t) noexcept;
    bool operator!=(std::nullptr_t, task_handle const& h) noexcept;

```

(continues on next page)

(continued from previous page)

```

} // namespace tbb
} // namespace oneapi

```

Member Functions

`task_handle()`

Creates an empty `task_handle` object.

`task_handle(task_handle &&src)`

Constructs `task_handle` object with the content of `src` using move semantics. `src` becomes empty after the construction.

`~task_handle()`

Destroys the `task_handle` object and associated task if it exists.

`task_handle &operator=(task_handle &&src)`

Replaces the content of `task_handle` object with the content of `src` using move semantics. `src` becomes empty after the assignment. The previously associated task object, if any, is destroyed before the assignment.

Returns: Reference to `*this`.

explicit `operator bool()` const noexcept

Checks if `*this` has an associated task object.

Returns: true if `*this` is not empty, false otherwise.

Non-Member Functions

```

bool operator==(task_handle const& h, std::nullptr_t) noexcept
bool operator==(std::nullptr_t, task_handle const& h) noexcept

```

Returns: true if `h` is empty, false otherwise.

```

bool operator!=(task_handle const& h, std::nullptr_t) noexcept
bool operator!=(std::nullptr_t, task_handle const& h) noexcept

```

Returns: true if `h` is not empty, false otherwise.

Task Arena

`task_arena`

[scheduler.task_arena]

A class that represents an explicit, user-managed task scheduler arena.

```

// Defined in header <oneapi/tbb/task_arena.h>

namespace oneapi {
    namespace tbb {

```

(continues on next page)

(continued from previous page)

```

class task_arena {
public:
    static const int automatic = /* unspecified */;
    static const int not_initialized = /* unspecified */;
    enum class priority : /* unspecified type */ {
        low = /* unspecified */,
        normal = /* unspecified */,
        high = /* unspecified */
    };

    struct constraints {
        constraints( numa_node_id numa_node_          = task_arena::automatic,
                    int max_concurrency_            = task_arena::automatic);

        constraints& set_numa_id( numa_node_id id);
        constraints& set_max_concurrency( int maximal_concurrency);
        constraints& set_core_type( core_type_id id);
        constraints& set_max_threads_per_core( int threads_number);

        numa_node_id numa_id = task_arena::automatic;
        int max_concurrency = task_arena::automatic;
        core_type_id core_type = task_arena::automatic;
        int max_threads_per_core = task_arena::automatic;
    };

    task_arena( int max_concurrency = automatic, unsigned reserved_for_masters = 1,
               priority a_priority = priority::normal);
    task_arena( constraints a_constraints, unsigned reserved_for_masters = 1,
               priority a_priority = priority::normal);
    task_arena( const task_arena &s);
    explicit task_arena( oneapi::tbb::attach);
    ~task_arena();

    void initialize();
    void initialize( int max_concurrency, unsigned reserved_for_masters = 1,
                   priority a_priority = priority::normal);
    void initialize( constraints a_constraints, unsigned reserved_for_masters = 1,
                   priority a_priority = priority::normal);
    void initialize( oneapi::tbb::attach);

    void terminate();

    bool is_active() const;
    int max_concurrency() const;

    template<typename F> auto execute( F&& f) -> decltype( f());
    template<typename F> void enqueue( F&& f);

    void enqueue( task_handle&& h);
};

```

(continues on next page)

(continued from previous page)

```

} // namespace tbb
} // namespace oneapi

```

A `task_arena` class represents a place where threads may share and execute tasks.

The number of threads that may simultaneously execute tasks in a `task_arena` is limited by its concurrency level.

Each user thread that invokes any parallel construction outside an explicit `task_arena` uses an implicit task arena representation object associated with the calling thread.

The tasks spawned or enqueued into one arena cannot be executed in another arena.

Each `task_arena` has a `priority`. The tasks from `task_arena` with higher priority are given a precedence in execution over the tasks from `task_arena` with lower priority.

Note: The `task_arena` constructors do not create an internal task arena representation object. It may already exist in case of the “attaching” constructor; otherwise, it is created by an explicit call to `task_arena::initialize` or lazily on first use.

Member types and constants

static const int **automatic**

When passed as `max_concurrency` to the specific constructor, arena concurrency is automatically set based on the hardware configuration.

static const int **not_initialized**

When returned by a method or function, indicates that there is no active `task_arena` or that the `task_arena` object has not yet been initialized.

enum `priority::low`

When passed to a constructor or the `initialize` method, the initialized `task_arena` has a lowered priority.

enum `priority::normal`

When passed to a constructor or the `initialize` method, the initialized `task_arena` has regular priority.

enum `priority::high`

When passed to a constructor or the `initialize` method, the initialized `task_arena` has a raised priority.

struct **constraints**

Represents limitations applied to threads within `task_arena`.

Starting from C++20 this class should be an aggregate type to support the designated initialization.

numa_node_id `constraints::numa_id`

An integral logical index uniquely identifying a NUMA node. If set to non-automatic value, then this NUMA node will be considered as preferred for all the threads within the arena.

Note: NUMA node ID is considered valid if it was obtained through `tbb::info::numa_nodes()`.

int `constraints::max_concurrency`

The maximum number of threads that can participate in work processing within the `task_arena` at the same time.

`core_type_id` *constraints::core_type*

An integral logical index uniquely identifying a core type. If set to non-automatic value, then this core type will be considered as preferred for all the threads within the arena.

Note: core type ID is considered valid if it was obtained through `tbb::info::core_types()`.

`int` *constraints::max_threads_per_core*

The maximum number of threads that can be scheduled to one core simultaneously.

constraints::constraints(`numa_node_id` `numa_node_ = task_arena::automatic`, `int` `max_concurrency_ = task_arena::automatic`)

Constructs the constraints object with the provided `numa_id` and `max_concurrency` settings.

Note: To support designated initialization this constructor is omitted starting from C++20. Aggregate initialization is supposed to be used instead.

constraints &constraints::set_numa_id(`numa_node_id` `id`)

Sets the `numa_id` to the provided `id`. Returns the reference to the updated constraints object.

constraints &constraints::set_max_concurrency(`int` `maximal_concurrency`)

Sets the `max_concurrency` to the provided `maximal_concurrency`. Returns the reference to the updated constraints object.

constraints &constraints::set_core_type(`core_type_id` `id`)

Sets the `core_type` to the provided `id`. Returns the reference to the updated constraints object.

constraints &constraints::set_max_threads_per_core(`int` `threads_number`)

Sets the `max_threads_per_core` to the provided `threads_number`. Returns the reference to the updated constraints object.

Member functions

task_arena(`int` `max_concurrency = automatic`, `unsigned` `reserved_for_masters = 1`, `priority` `a_priority = priority::normal`)

Creates a `task_arena` with a certain concurrency limit (`max_concurrency`) and priority (`a_priority`). Some portion of the limit can be reserved for application threads with `reserved_for_masters`. The amount for reservation cannot exceed the limit.

Caution: If `max_concurrency` and `reserved_for_masters` are explicitly set to be equal and greater than 1, oneTBB worker threads will never join the arena. As a result, the execution guarantee for enqueued tasks is not valid in such arena. Do not use `task_arena::enqueue()` with an arena set to have no worker threads.

task_arena(*constraints* `a_constraints`, `unsigned` `reserved_for_masters = 1`, `priority` `a_priority = priority::normal`)

Creates a `task_arena` with a certain constraints(`a_constraints`) and priority (`a_priority`). Some portion of the limit can be reserved for application threads with `reserved_for_masters`. The amount for reservation cannot exceed the concurrency limit specified in `constraints`.

Caution: If `constraints::max_concurrency` and `reserved_for_masters` are explicitly set to be equal and greater than 1, oneTBB worker threads will never join the arena. As a result, the execution guarantee

for enqueued tasks is not valid in such arena. Do not use `task_arena::enqueue()` with an arena set to have no worker threads.

If `constraints::numa_node` is specified, then all threads that enter the arena are automatically pinned to corresponding NUMA node.

task_arena(const *task_arena*&)

Copies settings from another `task_arena` instance.

explicit **task_arena**(oneapi::tbb::attach)

Creates an instance of `task_arena` that is connected to the internal task arena representation currently used by the calling thread. If no such arena exists yet, creates a `task_arena` with default parameters.

Note: Unlike other constructors, this one automatically initializes the new `task_arena` when connecting to an already existing arena.

~task_arena()

Destroys the `task_arena` instance, but the destruction may not be synchronized with any task execution inside this `task_arena`. It means that an internal task arena representation associated with this `task_arena` instance can be destroyed later. Not thread-safe for concurrent invocations of other methods.

void **initialize**()

Performs actual initialization of internal task arena representation.

Note: After the call to `initialize`, the arena parameters are fixed and cannot be changed.

void **initialize**(int max_concurrency, unsigned reserved_for_masters = 1, priority a_priority = priority::normal)

Same as above, but overrides previous arena parameters.

void **initialize**(*constraints* a_constraints, unsigned reserved_for_masters = 1, priority a_priority = priority::normal)

Same as above.

void **initialize**(oneapi::tbb::attach)

If an internal task arena representation currently used by the calling thread, the method ignores arena parameters and connects `task_arena` to that internal task arena representation. The method has no effect when called for an already initialized `task_arena`.

void **terminate**()

Removes the reference to the internal task arena representation without destroying the `task_arena` object, which can then be re-used. Not thread safe for concurrent invocations of other methods.

bool **is_active**() const

Returns `true` if the `task_arena` has been initialized; `false`, otherwise.

int **max_concurrency**() const

Returns the concurrency level of the `task_arena`. Does not require the `task_arena` to be initialized and does not perform initialization.

template<F>

void **enqueue**(F &&f)

Enqueues a task into the `task_arena` to process the specified functor and immediately returns. The F type must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard. The task is scheduled for eventual execution by a worker thread even if no thread ever explicitly waits for the task to

complete. If the total number of worker threads is zero, a special additional worker thread is created to execute enqueued tasks.

Note: The method does not require the calling thread to join the arena; that is, any number of threads outside of the arena can submit work to it without blocking.

Caution: There is no guarantee that tasks enqueued into an arena execute concurrently with respect to any other tasks there.

Caution: An exception thrown and not caught in the functor results in undefined behavior.

```
template<F>
```

```
auto execute(F &&f) -> decltype(f())
```

Executes the specified functor in the `task_arena` and returns the value returned by the functor. The `F` type must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard.

The calling thread joins the `task_arena` if possible, and executes the functor. Upon return it restores the previous task scheduler state and floating-point settings.

If joining the `task_arena` is not possible, the call wraps the functor into a task, enqueues it into the arena, waits using an OS kernel synchronization object for another opportunity to join, and finishes after the task completion.

An exception thrown in the functor will be captured and re-thrown from `execute`.

Note: Any number of threads outside of the arena can submit work to the arena and be blocked. However, only the maximal number of threads specified for the arena can participate in executing the work.

```
void enqueue(task_handle &&h)
```

Enqueues a task owned by `h` into the `task_arena` for processing.

The behavior of this function is identical to the generic version (`template<typename F> void task_arena::enqueue(F&& f)`), except parameter type.

Note: `h` should not be empty to avoid an undefined behavior.

Example

The example demonstrates `task_arena` NUMA support API. Each constructed `task_arena` is pinned to the corresponding NUMA node.

```
#include "oneapi/tbb/task_group.h"
#include "oneapi/tbb/task_arena.h"

#include <vector>

int main() {
    std::vector<oneapi::tbb::numa_node_id> numa_nodes = oneapi::tbb::info::numa_nodes();
```

(continues on next page)

(continued from previous page)

```

std::vector<oneapi::tbb::task_arena> arenas(uma_nodes.size());
std::vector<oneapi::tbb::task_group> task_groups(uma_nodes.size());

for (int i = 0; i < uma_nodes.size(); i++) {
    arenas[i].initialize(oneapi::tbb::task_arena::constraints(uma_nodes[i]));
}

for (int i = 0; i < uma_nodes.size(); i++) {
    arenas[i].execute([&task_groups, i] {
        task_groups[i].run([] {
            /* executed by the thread pinned to specified NUMA node */
        });
    });
}

for (int i = 0; i < uma_nodes.size(); i++) {
    arenas[i].execute([&task_groups, i] {
        task_groups[i].wait();
    });
}

return 0;
}

```

See also:

- *attach*
- *task_group*
- *task_scheduler_observer*

this_task_arena

[scheduler.this_task_arena]

The namespace for functions applicable to the current `task_arena`.

The namespace `this_task_arena` contains global functions for interaction with the `task_arena` currently used by the calling thread.

```

// Defined in header <oneapi/tbb/task_arena.h>

namespace oneapi {
namespace tbb {
    namespace this_task_arena {
        int current_thread_index();
        int max_concurrency();
        template<typename F> auto isolate(F&& f) -> decltype(f());

        void enqueue(task_handle&& h);

        template<typename F> void enqueue(F&& f) ;
    }
}
}

```

(continues on next page)

(continued from previous page)

```

} // namespace tbb
} // namespace oneapi

```

int **current_thread_index**()

Returns the thread index in a `task_arena` currently used by the calling thread, or `task_arena::not_initialized` if the thread has not yet initialized the task scheduler.

A thread index is an integer number between 0 and the `task_arena` concurrency level. Thread indexes are assigned to both application threads and worker threads on joining an arena and are kept until exiting the arena. Indexes of threads that share an arena are unique, that is, no two threads within the arena can have the same index at the same time - but not necessarily consecutive.

Note: Since a thread may exit the arena at any time if it does not execute a task, the index of a thread may change between any two tasks, even those belonging to the same task group or algorithm.

Note: Threads that use different arenas may have the same current index value.

Note: Joining a nested arena in `execute()` may change current index value while preserving the index in the outer arena which will be restored on return.

int **max_concurrency**()

Returns the concurrency level of the `task_arena` currently used by the calling thread. If the thread has not yet initialized the task scheduler, returns the concurrency level determined automatically for the hardware configuration.

template<F>

auto **isolate**(F &&f) -> decltype(f())

Runs the specified functor in isolation by restricting the calling thread to process only tasks scheduled in the scope of the functor (also called the isolation region). The function returns the value returned by the functor. The F type must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard.

Caution: The object returned by the functor cannot be a reference. `std::reference_wrapper` can be used instead.

template<typename F>

void **enqueue**(F &&f)

Enqueues a task into the `task_arena` currently used by the calling thread to process the specified functor, then returns immediately. The F type must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard.

Behavior of this function is identical to `template<typename F> void task_arena::enqueue(F&& f)` applied to the `task_arena` object constructed with `attach` parameter.

void **enqueue**(task_handle &&h)

Enqueues a task owned by `h` into the `task_arena` that is currently used by the calling thread.

The behavior of this function is identical to the generic version (`template<typename F> void enqueue(F&& f)`), except the parameter type.

Note: `h` should not be empty to avoid an undefined behavior.

task_scheduler_observer

[scheduler.task_scheduler_observer]

Class that represents thread interest in task scheduling services.

```
// Defined in header <oneapi/tbb/task_scheduler_observer.h>

namespace oneapi {
namespace tbb {

    class task_scheduler_observer {
    public:
        task_scheduler_observer();
        explicit task_scheduler_observer( task_arena& a );
        virtual ~task_scheduler_observer();

        void observe( bool state=true );
        bool is_observing() const;

        virtual void on_scheduler_entry( bool is_worker ) {}
        virtual void on_scheduler_exit( bool is_worker ) {}
    };

} // namespace tbb
} // namespace oneapi
```

A `task_scheduler_observer` permits clients to observe when a thread starts and stops processing tasks, either globally or in a certain task scheduler arena. You typically derive your own observer class from `task_scheduler_observer`, and override virtual methods `on_scheduler_entry` or `on_scheduler_exit`. Observation can be enabled and disabled for an observer instance; it is disabled on creation. Remember to call `observe()` to enable observation.

Exceptions thrown and not caught in the overridden methods of `task_scheduler_observer` result in undefined behavior.

Member functions

task_scheduler_observer()

Constructs a `task_scheduler_observer` object in the inactive state (observation is disabled). For a created observer, entry/exit notifications are invoked whenever a worker thread joins/leaves the arena of the observer's owner thread. If a thread is already in the arena when the observer is activated, the entry notification is called before it executes the first stolen task.

explicit task_scheduler_observer(task_arena&)

Constructs a `task_scheduler_observer` object for a given arena in inactive state (observation is disabled). For created observer, entry/exit notifications are invoked whenever a thread joins/leaves arena. If a thread is already in the arena when the observer is activated, the entry notification is called before it executes the first stolen task.

Constructs a `task_scheduler_observer` object in the inactive state (observation is disabled), which receives notifications from threads entering and exiting the specified `task_arena`.

`~task_scheduler_observer()`

Disables observing and destroys the observer instance. Waits for extant invocations of `on_scheduler_entry` and `on_scheduler_exit` to complete.

void `observe`(bool state = true)

Enables observing if `state` is true; disables observing if `state` is false.

bool `is_observing`() const

Returns: True if observing is enabled; false, otherwise.

virtual void `on_scheduler_entry`(bool is_worker)

The task scheduler invokes this method for each thread that starts participating in oneTBB work or enters an arena after the observation is enabled. For threads that already execute tasks, the method is invoked before executing the first task stolen after enabling the observation.

If a thread enables the observation and then spawns a task, it is guaranteed that the task, as well as all the tasks it creates, will be executed by threads which have invoked `on_scheduler_entry`.

The flag `is_worker` is true if the thread was created by oneTBB; false, otherwise.

Effects: The default behavior does nothing.

virtual void `on_scheduler_exit`(bool is_worker)

The task scheduler invokes this method when a thread stops participating in task processing or leaves an arena.

Caution: A process does not wait for the worker threads to clean up, and can terminate before `on_scheduler_exit` is invoked.

Effects: The default behavior does nothing.

Example

The following example sketches the code of an observer that pins oneTBB worker threads to hardware threads.

```
class pinning_observer : public oneapi::tbb::task_scheduler_observer {
public:
    affinity_mask_t m_mask; // HW affinity mask to be used for threads in an arena
    pinning_observer( oneapi::tbb::task_arena &a, affinity_mask_t mask )
        : oneapi::tbb::task_scheduler_observer(a), m_mask(mask) {
        observe(true); // activate the observer
    }
    void on_scheduler_entry( bool worker ) override {
        set_thread_affinity(oneapi::tbb::this_task_arena::current_thread_index(), m_
↪mask);
    }
    void on_scheduler_exit( bool worker ) override {
        restore_thread_affinity();
    }
};
```

Helper types

attach tag type

[scheduler.attach]

An attach tag type is specifically used with `task_arena` and `task_scheduler_handle` interfaces. It is guaranteed to be constructible by default.

```

namespace oneapi {
    namespace tbb {
        using attach = /* unspecified */
    }
}

```

- `task_arena`
- `task_scheduler_handle`

9.2.5 Containers

[containers]

The container classes provided by oneAPI Threading Building Blocks (oneTBB) permit multiple threads to simultaneously invoke certain methods on the same container.

Sequences

concurrent_vector

[containers.concurrent_vector]

`concurrent_vector` is a class template for a vector that can be concurrently grown and accessed.

Class Template Synopsis

```

// Defined in header <oneapi/tbb/concurrent_vector.h>

namespace oneapi {
    namespace tbb {

        template <typename T,
                 typename Allocator = cache_aligned_allocator<T>>
        class concurrent_vector {
            using value_type = T;
            using allocator_type = Allocator;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

```

(continues on next page)

(continued from previous page)

```

using reference = value_type&;

allocator_type get_allocator() const;

// Parallel iteration
range_type range( size_type grainsize = 1 );
const_range_type range( size_type grainsize = 1 ) const;
}; // class concurrent_vector

} // namespace tbb
} // namespace oneapi

```

Requirements

- The type T must meet the following requirements:
 - Requirements of Erasable from the [container.requirements] ISO C++ Standard section.
 - Its destructor must not throw an exception.
 - If its default constructor can throw an exception, the destructor must be non-virtual and work correctly on zero-filled memory.
 - Member functions can impose stricter requirements depending on the type of the operation.
- The type Allocator must meet the Allocator requirements from the [allocator.requirements] ISO C++ section.

Description

`oneapi::tbb::concurrent_vector` is a class template that represents a sequence container with the following features:

- Multiple threads can concurrently grow the container and append new elements.
- Random access by index. The index of the first element is zero.
- Growing the container does not invalidate any existing iterators or indices.

Exception Safety

Concurrent growing is fundamentally incompatible with ideal exception safety. Nonetheless, `oneapi::tbb::concurrent_vector` offers a practical level of exception safety.

Growth and vector assignment append a sequence of elements to a vector. If an exception occurs, the impact on the vector depends on the cause of the exception:

- If the exception is thrown by the constructor of an element, all subsequent elements in the appended sequence will be zero-filled.
- Otherwise, the exception is thrown by the vector allocator. The vector becomes broken. Each element in the appended sequence will be in one of three states:
 - constructed
 - zero-filled
 - unallocated in memory

Once a vector becomes broken, note the following when accessing it:

- Accessing an unallocated element with the method `at` causes an exception `std::range_error`. Accessing an unallocated element using any other method has undefined behavior.
- The values of `capacity()` and `size()` may be less than expected.
- Access to a broken vector via `back()` has undefined behavior.

However, the following guarantees hold for broken or unbroken vectors:

- Let `k` be an index of an unallocated element. Then `size() <= capacity() <= k`.
- Growth operations never cause `size()` or `capacity()` to decrease.

If a concurrent growth operation successfully completes, the appended sequence remains valid and accessible even if a subsequent growth operations fails.

Member functions

Construction, destruction, copying

Empty container constructors

```
concurrent_vector();

explicit concurrent_vector( const allocator_type& alloc );
```

Constructs an empty `concurrent_vector`.

If provided, uses the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```
explicit concurrent_vector( size_type count, const value_type& value,
                           const allocator_type& alloc = allocator_type() );
```

Constructs a `concurrent_vector` containing `count` copies of the value using the allocator `alloc`.

```
explicit concurrent_vector( size_type count,
                           const allocator_type& alloc = allocator_type() );
```

Constructs a `concurrent_vector` containing `n` default constructed in-place elements using the allocator `alloc`.

```
template <typename InputIterator>
concurrent_vector( InputIterator first, InputIterator last,
                  const allocator_type& alloc = allocator_type() );
```

Constructs a `concurrent_vector` contains all elements from the half-open interval `[first, last)` using the allocator `alloc`.

Requirements: the type `InputIterator` must meet the requirements of `InputIterator` from the `[input.iterators]` ISO C++ Standard section.

```
concurrent_vector( std::initializer_list<value_type> init,
                  const allocator_type& alloc = allocator_type() );
```

Equivalent to `concurrent_vector(init.begin(), init.end(), alloc)`.

Copying constructors

```
concurrent_vector( const concurrent_vector& other );

concurrent_vector( const concurrent_vector& other,
                  const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_vector( concurrent_vector&& other );

concurrent_vector( concurrent_vector&& other,
                  const allocator_type& alloc );
```

Constructs a `concurrent_vector` with the contents of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_vector();
```

Destroys the `concurrent_vector`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_vector& operator=( const concurrent_vector& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_vector& operator=( concurrent_vector&& other ) noexcept( /*See ↪ below*/ );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

Exceptions: `noexcept` specification:

```
noexcept(std::allocator_traits<allocator_type>::propagate_on_container_
↳move_assignment::value ||
        std::allocator_traits<allocator_type>::is_always_equal::value)
```

```
concurrent_vector& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in **this* by the elements in *init*.

The behavior is undefined in case of concurrent operations with **this*.

Returns: a reference to **this*.

assign

```
void assign( size_type count, const value_type& value );
```

Replaces all elements in **this* by *count* copies of *value*.

```
template <typename InputIterator>
void assign( InputIterator first, InputIterator last );
```

Replaces all elements in **this* by the elements from the half-open interval [*first*, *last*).

This overload only participates in overload resolution if the type *InputIterator* meets the requirements of *InputIterator* from the [input.iterators] ISO C++ Standard section.

```
void assign( std::initializer_list<value_type> init );
```

Equivalent to `assign(init.begin(), init.end())`.

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with **this*.

Concurrent growth

All member functions in this section can be performed concurrently with each other, element access methods and while traversing the container.

grow_by

```
iterator grow_by( size_type delta );
```

Appends a sequence comprising `delta` new default-constructed in-place elements to the end of the vector.

Returns: iterator to the beginning of the appended sequence.

Requirements: the type `value_type` must meet the `DefaultConstructible` and `EmplaceConstructible` requirements from `[defaultconstructible]` and `[container.requirements]` ISO C++ sections.

```
iterator grow_by( size_type delta, const value_type& value );
```

Appends a sequence comprising `delta` copies of `value` to the end of the vector.

Returns: iterator to the beginning of the appended sequence.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the `[container.requirements]` ISO C++ Standard section.

```
template <typename InputIterator>
iterator grow_by( InputIterator first, InputIterator last );
```

Appends a sequence comprising all elements from the half-open interval `[first, last)` to the end of the vector.

Returns: iterator to the beginning of the appended sequence.

This overload participates in overload resolution only if the type `InputIterator` meets the requirements of *InputIterator* from the `[input.iterators]` ISO C++ Standard section.

```
iterator grow_by( std::initializer_list<value_type> init );
```

Equivalent to `grow_by(init.begin(), init.end())`.

grow_to_at_least

```
iterator grow_to_at_least( size_type n );
```

Appends minimal sequence of default constructed in-place elements such that `size() >= n`.

Returns: iterator to the beginning of the appended sequence.

Requirements: the type `value_type` must meet the `DefaultConstructible` and `EmplaceConstructible` requirements from `[defaultconstructible]` and `[container.requirements]` ISO C++ sections.

```
iterator grow_to_at_least( size_type n, const value_type& value );
```

Appends minimal sequence of comprising copies of value such that size() >= n.

Returns: iterator to the beginning of the appended sequence.

Requirements: the type value_type must meet the CopyInsertable requirements from the [container.requirements] ISO C++ Standard section.

push_back

```
iterator push_back( const value_type& value );
```

Appends a copy of value to the end of the vector.

Returns: iterator to the appended element.

Requirements: the type value_type must meet the CopyInsertable requirements from the [container.requirements] ISO C++ Standard section.

```
iterator push_back( value_type&& value );
```

Appends value to the end of the vector using move semantics.

value is left in a valid, but unspecified state.

Returns: iterator to the appended element.

Requirements: the type value_type must meet the MoveInsertable requirements from the [container.requirements] ISO C++ Standard section.

emplace_back

```
template <typename... Args>
iterator emplace_back( Args&&... args );
```

Appends an element constructed in-place from args to the end of the vector.

Returns: iterator to the appended element.

Requirements: the type value_type must meet the EmplaceConstructible requirements from the [container.requirements] ISO C++ section.

Element access

All member functions in this section can be performed concurrently with each other, concurrent growth methods and while traversing the container.

In case of concurrent growth, the element returned by the access method can refer to the element that is under construction of the other thread.

Access by index

```
value_type& operator[]( size_type index );
const value_type& operator[]( size_type index ) const;
```

Returns: a reference to the element on the position `index`.

The behavior is undefined if `index() >= size()`.

```
value_type& at( size_type index );
const value_type& at( size_type index ) const;
```

Returns: a reference to the element on the position `index`.

Throws:

- `std::out_of_range` if `index >= size()`.
- `std::range_error` if the vector is broken and the element on the position `index` unallocated.

Access the first and the last element

```
value_type& front();
const value_type& front() const;
```

Returns: a reference to the first element in the vector.

```
value_type& back();
const value_type& back() const;
```

Returns: a reference to the last element in the vector.

Iterators

The types `concurrent_vector::iterator` and `concurrent_vector::const_iterator` meet the requirements of `RandomAccessIterator` from the [random.access.iterators] ISO C++ Standard section.

begin and cbegin

```
iterator begin();
const_iterator begin() const;
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the vector.

end and cend

```
iterator end();  
const_iterator end() const;  
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the vector.

rbegin and crbegin

```
reverse_iterator rbegin();  
const_reverse_iterator rbegin() const;  
const_reverse_iterator crbegin() const;
```

Returns: a reverse iterator to the first element of the reversed vector.

rend and crend

```
reverse_iterator rend();  
const_reverse_iterator rend() const;  
const_reverse_iterator crend() const;
```

Returns: a reverse iterator that follows the last element of the reversed vector.

Size and capacity

size

```
size_type size() const noexcept;
```

Returns: the number of elements in the vector.

empty

```
bool empty() const noexcept;
```

Returns: true if the vector is empty; false, otherwise.

max_size

```
size_type max_size() const noexcept;
```

Returns: the maximum number of elements that the vector can hold.

capacity

```
size_type capacity() const noexcept;
```

Returns: the maximum number of elements that the vector can hold without allocating more memory.

Concurrently unsafe operations

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Reserving

```
void reserve( size_type n );
```

Reserves memory for at least n elements.

Throws: `std::length_error` if $n > \text{max_size}()$.

Resizing

```
void resize( size_type n );
```

If $n < \text{size}()$, the vector is reduced to its first n elements.

Otherwise, appends $n - \text{size}()$ new elements default-constructed in-place to the end of the vector.

```
void resize( size_type n, const value_type& value );
```

If $n < \text{size}()$, the vector is reduced to its first n elements.

Otherwise, appends $n - \text{size}()$ copies of `value` to the end of the vector.

shrink_to_fit

```
void shrink_to_fit();
```

Removes the unused capacity of the vector.

Call for this method can also reorganize the internal vector representation in the memory.

clear

```
void clear();
```

Removes all elements from the container.

swap

```
void swap( concurrent_vector& other ) noexcept( /*See below*/ );
```

Swaps contents of **this* and *other*.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Exceptions: `noexcept` specification:

```
noexcept( std::allocator_traits<allocator_type>::propagate_on_container_
↵ swap::value ||
          std::allocator_traits<allocator_type>::is_always_equal::value
```

Parallel iteration

Member types `concurrent_vector::range_type` and `concurrent_vector::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_vector::const_range_type` are of type `concurrent_vector::const_iterator`, whereas the bounds for a `concurrent_vector::range_type` are of type `concurrent_vector::iterator`.

range member function

```
range_type range( size_type grainsize = 1 );
const_range_type range( size_type grainsize = 1 ) const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provide binary and lexicographical comparison and swap operations on `oneapi::tbb::concurrent_vector` objects.

The exact namespace where these functions are defined is unspecified, as long as they can be used in respective comparison operations. For example, an implementation can define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_vector` as a type alias, for which the non-member functions are reachable only via argument-dependent lookup.

```

template <typename T, typename Allocator>
bool operator==( const concurrent_vector<T, Allocator>& lhs,
                 const concurrent_vector<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator!=( const concurrent_vector<T, Allocator>& lhs,
                 const concurrent_vector<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator<( const concurrent_vector<T, Allocator>& lhs,
                const concurrent_vector<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator<=( const concurrent_vector<T, Allocator>& lhs,
                 const concurrent_vector<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator>( const concurrent_vector<T, Allocator>& lhs,
                const concurrent_vector<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator>=( const concurrent_vector<T, Allocator>& lhs,
                 const concurrent_vector<T, Allocator>& rhs );

template <typename T, typename Allocator>
void swap( concurrent_vector<T, Allocator>& lhs,
           concurrent_vector<T, Allocator>& rhs );

```

Non-member binary comparisons

Two objects of `concurrent_vector` are equal if:

- they contains an equal number of elements.
- the elements on the same positions are equal.

```

template <typename T, typename Allocator>
bool operator==( const concurrent_vector<T, Allocator>& lhs,
                 const concurrent_vector<T, Allocator>& rhs );

```

Returns: true if lhs is equal to rhs, false otherwise.

```
template <typename T, typename Allocator>
bool operator!=( const concurrent_vector<T, Allocator>& lhs,
                 const concurrent_vector<T, Allocator>& rhs );
```

Returns: true if lhs is not equal to rhs, false otherwise.

Non-member lexicographical comparisons

```
template <typename T, typename Allocator>
bool operator<( const concurrent_vector<T, Allocator>& lhs,
                const concurrent_vector<T, Allocator>& rhs );
```

Returns: true if lhs is lexicographically *less* than rhs; false, otherwise.

```
template <typename T, typename Allocator>
bool operator<=( const concurrent_vector<T, Allocator>& lhs,
                 const concurrent_vector<T, Allocator>& rhs );
```

Returns: true if lhs is lexicographically *less or equal* than rhs; false, otherwise.

```
template <typename T, typename Allocator>
bool operator>( const concurrent_vector<T, Allocator>& lhs,
                const concurrent_vector<T, Allocator>& rhs );
```

Returns: true if lhs is lexicographically *greater* than rhs; false, otherwise.

```
template <typename T, typename Allocator>
bool operator>=( const concurrent_vector<T, Allocator>& lhs,
                 const concurrent_vector<T, Allocator>& rhs );
```

Returns: true if lhs is lexicographically *greater or equal* than rhs; false, otherwise.

Non-member swap

```
template <typename T, typename Allocator>
void swap( concurrent_vector<T, Allocator>& lhs,
           concurrent_vector<T, Allocator>& rhs );
```

Equivalent to `lhs.swap(rhs)`.

Other

Deduction guides

If possible, `concurrent_vector` constructors support class template argument deduction (since C++17). The following constructors provide implicitly-generated deduction guides:

- Copy and move constructors, including constructors with explicit `allocator_type` argument
- Constructors, accepting `std::initializer_list` as an argument

In addition, the following explicit deduction guide is provided:

```

template <typename InputIterator,
         typename Allocator = tbb::cache_aligned_allocator<iterator_value_t
↪<InputIterator>>>
concurrent_vector( InputIterator, InputIterator,
                  Allocator = Allocator() )
-> concurrent_vector<iterator_value_t<InputIterator>,
                  Allocator>;

```

Where type alias `iterator_value_t` defines as follows:

```

template <typename InputIterator>
using iterator_value_t = typename std::iterator_traits<InputIterator>::value_type;

```

This deduction guide only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.

Example

```

#include <oneapi/tbb/concurrent_vector.h>
#include <array>
#include <memory>

int main() {
    std::array<int, 100> arr;

    // Deduces cv1 as oneapi::tbb::concurrent_vector<int>
    oneapi::tbb::concurrent_vector cv1(arr.begin(), arr.end());

    std::allocator<int> alloc;

    // Deduces cv2 as oneapi::tbb::concurrent_vector<int, std::allocator<int>>
    oneapi::tbb::concurrent_vector cv2(arr.begin(), arr.end(), alloc);
}

```

Queues

concurrent_queue

[containers.concurrent_queue]

`oneapi::tbb::concurrent_queue` is a class template for an unbounded first-in-first-out data structure that permits multiple threads to concurrently push and pop items.

Class Template Synopsis

```

// Defined in header <oneapi/tbb/concurrent_queue.h>

namespace oneapi {
    namespace tbb {

        template <typename T, typename Allocator = cache_aligned_allocator<T>>
        class concurrent_queue {
        public:
            using value_type = T;
            using reference = T&;
            using const_reference = const T&;
            using pointer = typename std::allocator_traits<Allocator>::pointer;
            using const_pointer = typename std::allocator_traits<Allocator>::const_
↳pointer;
            using allocator_type = Allocator;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using iterator = <implementation-defined ForwardIterator>;
            using const_iterator = <implementation-defined constant ForwardIterator>;

            // Construction, destruction, copying
            concurrent_queue();

            explicit concurrent_queue( const allocator_type& alloc );

            template <typename InputIterator>
            concurrent_queue( InputIterator first, InputIterator last,
                const allocator_type& alloc = allocator_type() );

            concurrent_queue( std::initializer_list<value_type> init,
                const allocator_type& alloc = allocator_type() );

            concurrent_queue( const concurrent_queue& other );
            concurrent_queue( const concurrent_queue& other, const allocator_type& alloc_
↳);

            concurrent_queue( concurrent_queue&& other );
            concurrent_queue( concurrent_queue&& other, const allocator_type& alloc );

            ~concurrent_queue();

            concurrent_queue& operator=( const concurrent_queue& other );
            concurrent_queue& operator=( concurrent_queue&& other );
            concurrent_queue& operator=( std::initializer_list<value_type> init );

            template <typename InputIterator>
            void assign( InputIterator first, InputIterator last );

```

(continues on next page)

(continued from previous page)

```

void assign( std::initializer_list<value_type> init );

void swap( concurrent_queue& other );

void push( const value_type& value );
void push( value_type&& value );

template <typename... Args>
void emplace( Args&&... args );

bool try_pop( value_type& result );

allocator_type get_allocator() const;

size_type unsafe_size() const;
bool empty() const;

void clear();

iterator unsafe_begin();
const_iterator unsafe_begin() const;
const_iterator unsafe_cbegin() const;

iterator unsafe_end();
const_iterator unsafe_end() const;
const_iterator unsafe_cend() const;
}; // class concurrent_queue

} // namespace tbb
} // namespace oneapi

```

Requirements:

- The type T must meet the Erasable requirements from the [container.requirements] ISO C++ Standard section. Member functions can impose stricter requirements depending on the type of the operation.
- The type Allocator must meet the Allocator requirements from the [allocator.requirements] ISO C++ Standard section.

Member functions**Construction, destruction, copying****Empty container constructors**

```

concurrent_queue();

explicit concurrent_queue( const allocator_type& alloc );

```

Constructs an empty `concurrent_queue`. If provided, uses the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```
template <typename InputIterator>
concurrent_queue( InputIterator first, InputIterator last,
                 const allocator_type& alloc = allocator_type() );
```

Constructs a `concurrent_queue` containing all elements from the half-open interval `[first, last)` using the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the *InputIterator* requirements from the `[input.iterators]` ISO C++ Standard section.

```
concurrent_queue( std::initializer_list<value_type> init,
                 const allocator_type& alloc = allocator_type() );
```

Equivalent to `concurrent_queue(init.begin(), init.end(), alloc)`.

Copying constructors

```
concurrent_queue( const concurrent_queue& other );

concurrent_queue( const concurrent_queue& other,
                 const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by `std::allocator_traits<allocator_type>::select_on_container_get_allocator()`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_queue( concurrent_queue&& other );

concurrent_queue( concurrent_queue&& other,
                 const allocator_type& alloc );
```

Constructs a `concurrent_queue` with the content of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_queue();
```

Destroys the `concurrent_queue`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_queue& operator=( const concurrent_queue& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::is true`.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_queue& operator=( concurrent_queue&& other );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::is true`.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_queue& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

assign

```
template <typename InputIterator>
void assign( InputIterator first, InputIterator last );
```

Replaces all elements in `*this` by the elements in the half-open interval `[first, last)`.

The behavior is undefined in case of concurrent operations with `*this`.

Requirements: the type `InputIterator` must meet the *InputIterator* requirements from the [input.iterators] ISO C++ Standard section.

```
void assign( std::initializer_list<value_type> init );
```

Equivalent to `assign(init.begin(), init.end())`.

Concurrently safe member functions

All member functions in this section can be performed concurrently with each other.

Pushing elements

```
void push( const value_type& value );
```

Pushes a copy of `value` into the container.

Requirements: the type `T` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
void push( value_type&& value );
```

Pushes `value` into the container using move semantics.

Requirements: the type `T` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

`value` is left in a valid, but unspecified state.

```
template <typename... Args>  
void emplace( Args&&... args );
```

Pushes a new element constructed from `args` into the container.

Requirements: the type `T` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

Popping elements

```
bool try_pop( value_type& value );
```

If the container is empty, does nothing.

Otherwise, copies the last element from the container and assigns it to `value`. The popped element is destroyed.

Requirements: the type `T` must meet the `MoveAssignable` requirements from the [moveassignable] ISO C++ Standard section.

Returns: `true` if the element was popped; `false`, otherwise.

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator, associated with `*this`.

Concurrently unsafe member functions

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these methods with other (either concurrently safe) methods.

The number of elements

```
size_type unsafe_size() const;
```

Returns: the number of elements in the container.

```
bool empty() const;
```

Returns: `true` if the container is empty; `false`, otherwise.

clear

```
void clear();
```

Removes all elements from the container.

swap

```
void swap( concurrent_queue& other );
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is `true`.

Otherwise if `get_allocator() != other.get_allocator()` the behavior is undefined.

Iterators

The types `concurrent_queue::iterator` and `concurrent_queue::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these methods with other (either concurrently safe) methods.

unsafe_begin and unsafe_cbegin

```

iterator unsafe_begin();

const_iterator unsafe_begin() const;

const_iterator unsafe_cbegin() const;

```

Returns: an iterator to the first element in the container.

unsafe_end and unsafe_cend

```

iterator unsafe_end();

const_iterator unsafe_end() const;

const_iterator unsafe_cend() const;

```

Returns: an iterator to the element that follows the last element in the container.

Non-member functions

These functions provides binary comparison and swap operations on `oneapi::tbb::concurrent_queue` objects.

The exact namespace where this function is defined is unspecified, as long as it may be used in respective operation. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_queue` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```

template <typename T, typename Allocator>
void swap( concurrent_queue<T, Allocator>& lhs,
           concurrent_queue<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator==( const concurrent_queue<T, Allocator>& lhs,
                 const concurrent_queue<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator!=( const concurrent_queue<T, Allocator>& lhs,
                 const concurrent_queue<T, Allocator>& rhs );

```

Non-member swap

```

template <typename T, typename Allocator>
void swap( concurrent_queue<T, Allocator>& lhs,
           concurrent_queue<T, Allocator>& rhs );

```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

```
template <typename T, typename Allocator>
bool operator==( const concurrent_queue<T, Allocator>& lhs,
                 const concurrent_queue<T, Allocator>& rhs );
```

Checks if lhs is equal to rhs, that is they have the same number of elements and lhs contains all elements from rhs.

Returns: true if lhs is equal to rhs; false, otherwise.

```
template <typename T, typename Allocator>
bool operator!=( const concurrent_queue<T, Allocator>& lhs,
                 const concurrent_queue<T, Allocator>& rhs );
```

Equivalent to `!(lhs == rhs)`.

Returns: true if lhs is not equal to rhs; false, otherwise.

Other

Deduction guides

If possible, `oneapi::tbb::concurrent_queue` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guide is provided:

```
template <typename InputIterator,
         typename Allocator = tbb::cache_aligned_allocator<iterator_value_t
↔<InputIterator>>
concurrent_queue( InputIterator, InputIterator,
                 Allocator = Allocator() )
-> concurrent_queue<iterator_value_t<InputIterator>,
                 Allocator>;
```

Where the type alias `iterator_value_t` is defined as follows:

```
template <typename InputIterator>
using iterator_value_t = typename std::iterator_traits<InputIterator>::value_type;
```

This deduction guide only participates in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.

Example

```
#include <oneapi/tbb/concurrent_queue.h>
#include <vector>
#include <memory>

int main() {
```

(continues on next page)

(continued from previous page)

```

std::vector<int> vec;

// Deduces cq1 as oneapi::tbb::concurrent_queue<int>
oneapi::tbb::concurrent_queue cq1(vec.begin(), vec.end());

// Deduces cq2 as oneapi::tbb::concurrent_queue<int, std::allocator<int>>
oneapi::tbb::concurrent_queue cq2(vec.begin(), vec.end(), std::allocator<int>{ })
}

```

concurrent_bounded_queue

[containers.concurrent_bounded_queue]

oneapi::tbb::concurrent_bounded_queue is a class template for a bounded first-in-first-out data structure that permits multiple threads to concurrently push and pop items.

Class Template Synopsis

```

// Defined in header <oneapi/tbb/concurrent_queue.h>

namespace oneapi {
    namespace tbb {

        template <typename T, typename Allocator = cache_aligned_allocator<T>>
        class concurrent_bounded_queue {
        public:
            using value_type = T;
            using reference = T&;
            using const_reference = const T&;
            using pointer = typename std::allocator_traits<Allocator>::pointer;
            using const_pointer = typename std::allocator_traits<Allocator>::const_
            ⇨pointer;

            using allocator_type = Allocator;

            using size_type = <implementation-defined signed integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using iterator = <implementation-defined ForwardIterator>;
            using const_iterator = <implementation-defined constant ForwardIterator>;

            concurrent_bounded_queue();

            explicit concurrent_bounded_queue( const allocator_type& alloc );

            template <typename InputIterator>
            concurrent_bounded_queue( InputIterator first, InputIterator last,
                                     const allocator_type& alloc = allocator_type() );

            concurrent_bounded_queue( std::initializer_list<value_type> init,

```

(continues on next page)

(continued from previous page)

```

        const allocator_type& alloc = allocator_type() );

concurrent_bounded_queue( const concurrent_bounded_queue& other );
concurrent_bounded_queue( const concurrent_bounded_queue& other,
        const allocator_type& alloc );

concurrent_bounded_queue( concurrent_bounded_queue&& other );
concurrent_bounded_queue( concurrent_bounded_queue&& other,
        const allocator_type& alloc );

~concurrent_bounded_queue();

concurrent_bounded_queue& operator=( const concurrent_bounded_queue& other );
concurrent_bounded_queue& operator=( concurrent_bounded_queue&& other );
concurrent_bounded_queue& operator=( std::initializer_list<value_type> init_
→);

template <typename InputIterator>
void assign( InputIterator first, InputIterator last );

void assign( std::initializer_list<value_type> init );

void swap( concurrent_bounded_queue& other );

allocator_type get_allocator() const;

void push( const value_type& value );
void push( value_type&& value );

bool try_push( const value_type& value );
bool try_push( value_type&& value );

template <typename... Args>
void emplace( Args&&... args );

template <typename... Args>
bool try_emplace( Args&&... args );

void pop( value_type& result );

bool try_pop( value_type& result );

void abort();

size_type size() const;

bool empty() const;

size_type capacity() const;
void set_capacity( size_type new_capacity );

void clear();

```

(continues on next page)

(continued from previous page)

```

        iterator unsafe_begin();
        const_iterator unsafe_begin() const;
        const_iterator unsafe_cbegin() const;

        iterator unsafe_end();
        const_iterator unsafe_end() const;
        const_iterator unsafe_cend() const;
    }; // class concurrent_bounded_queue

} // namespace tbb
} // namespace oneapi

```

Requirements:

- The type T must meet the Erasable requirements from the [container.requirements] ISO C++ Standard section. Member functions can impose stricter requirements depending on the type of the operation.
- The type Allocator must meet the Allocator requirements from the [allocator.requirements] ISO C++ Standard section.

Member functions

Construction, destruction, copying

Empty container constructors

```

concurrent_bounded_queue();

explicit concurrent_bounded_queue( const allocator_type& alloc );

```

Constructs an empty `concurrent_bounded_queue` with an unbounded capacity. If provided, uses the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```

template <typename InputIterator>
concurrent_bounded_queue( InputIterator first, InputIterator last,
                          const allocator_type& alloc = allocator_type() );

```

Constructs a `concurrent_bounded_queue` with an unbounded capacity and containing all elements from the half-open interval `[first, last)` using the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the *InputIterator* requirements from the [input.iterators] ISO C++ Standard section.

```

concurrent_bounded_queue( std::initializer_list<value_type> init,
                          const allocator_type& alloc = allocator_type() );

```

Equivalent to `concurrent_bounded_queue(init.begin(), init.end(), alloc)`.

Copying constructors

```
concurrent_bounded_queue( const concurrent_bounded_queue& other );

concurrent_bounded_queue( const concurrent_bounded_queue& other,
                          const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by `std::allocator_traits<allocator_type>::select_on_container_get_allocator()`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_bounded_queue( concurrent_bounded_queue&& other );

concurrent_bounded_queue( concurrent_bounded_queue&& other,
                          const allocator_type& alloc );
```

Constructs a `concurrent_bounded_queue` with the content of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_bounded_queue();
```

Destroys the `concurrent_bounded_queue`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_bounded_queue& operator=( const concurrent_bounded_queue& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_bounded_queue& operator=( concurrent_bounded_queue&& other );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_bounded_queue& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

assign

```
template <typename InputIterator>
void assign( InputIterator first, InputIterator last );
```

Replaces all elements in `*this` by the elements in the half-open interval `[first, last)`.

The behavior is undefined in case of concurrent operations with `*this`.

Requirements: the type `InputIterator` must meet the *InputIterator* requirements from the [input.iterators] ISO C++ Standard section.

```
void assign( std::initializer_list<value_type> init );
```

Equivalent to `assign(init.begin(), init.end())`.

Concurrently safe member functions

All member functions in this section can be performed concurrently with each other.

Pushing elements

```
void push( const value_type& value );
```

Waits until the number of items in the queue is less than the capacity and pushes a copy of `value` into the container.

Requirements: the type `T` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
bool try_push( const value_type& value );
```

If the number of items in the queue is less than the capacity, pushes a copy of `value` into the container.

Requirements: the type `T` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

Returns: true if the item was pushed; false, otherwise.

```
void push( value_type&& value );
```

Waits until the number of items in the queue is less than `capacity()` and pushes `value` into the container using move semantics.

Requirements: the type `T` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

`value` is left in a valid, but unspecified state.

```
bool try_push( value_type&& value );
```

If the number of items in the queue is less than the capacity, pushes `value` into the container using move semantics.

Requirements: the type `T` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

`value` is left in a valid, but unspecified state.

Returns: true if the item was pushed; false, otherwise.

```
template <typename... Args>
void emplace( Args&&... args );
```

Waits until the number of items in the queue is less than `capacity()` and pushes a new element constructed from `args` into the container.

Requirements: the type `T` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

```
template <typename... Args>
bool try_emplace( Args&&... args );
```

If the number of items in the queue is less than the capacity, pushes a new element constructed from `args` into the container.

Requirements: the type `T` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

Returns: true if the item was pushed; false, otherwise.

Popping elements

```
void pop( value_type& value );
```

Waits until the item becomes available, copies it from the container, and assigns it to the `value`. The popped element is destroyed.

Requirements: the type `T` must meet the `MoveAssignable` requirements from the [moveassignable] ISO C++ Standard section.

```
bool try_pop( value_type& value );
```

If the container is empty, does nothing.

Otherwise, copies the last element from the container and assigns it to the `value`. The popped element is destroyed.

Requirements: the type `T` must meet the `MoveAssignable` requirements from the [moveassignable] ISO C++ Standard section.

Returns: `true` if the element was popped; `false`, otherwise.

abort

```
void abort();
```

Wakes up any threads that are waiting on the queue via `push`, `pop`, or `emplace` operations and raises the `oneapi::tbb::user_abort` exception on those threads.

Capacity of the queue

```
size_type capacity() const;
```

Returns: the maximum number of items that the queue can hold.

```
void set_capacity( size_type new_capacity ) const;
```

Sets the maximum number of items that the queue can hold to `new_capacity`.

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator, associated with `*this`.

Concurrently unsafe member functions

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these methods with other (either concurrently safe) methods.

The number of elements

```
size_type size() const;
```

Returns: the number of elements in the container.

```
bool empty() const;
```

Returns: true if the container is empty; false, otherwise.

clear

```
void clear();
```

Removes all elements from the container.

swap

```
void swap( concurrent_bounded_queue& other );
```

Swaps contents of *this and other.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise if `get_allocator() != other.get_allocator()` the behavior is undefined.

Iterators

The types `concurrent_bounded_queue::iterator` and `concurrent_bounded_queue::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these methods with other (either concurrently safe) methods.

unsafe_begin and unsafe_cbegin

```
iterator unsafe_begin();
const_iterator unsafe_begin() const;
const_iterator unsafe_cbegin() const;
```

Returns: an iterator to the first element in the container.

unsafe_end and unsafe_cend

```

iterator unsafe_end();

const_iterator unsafe_end() const;

const_iterator unsafe_cend() const;

```

Returns: an iterator to the element that follows the last element in the container.

Non-member functions

These functions provides binary comparison and swap operations on `oneapi::tbb::concurrent_bounded_queue` objects.

The exact namespace where this function is defined is unspecified, as long as it may be used in respective operation. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_bounded_queue` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```

template <typename T, typename Allocator>
void swap( concurrent_bounded_queue<T, Allocator>& lhs,
           concurrent_bounded_queue<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator==( const concurrent_bounded_queue<T, Allocator>& lhs,
                 const concurrent_bounded_queue<T, Allocator>& rhs );

template <typename T, typename Allocator>
bool operator!=( const concurrent_bounded_queue<T, Allocator>& lhs,
                 const concurrent_bounded_queue<T, Allocator>& rhs );

```

Non-member swap

```

template <typename T, typename Allocator>
void swap( concurrent_bounded_queue<T, Allocator>& lhs,
           concurrent_bounded_queue<T, Allocator>& rhs );

```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

```

template <typename T, typename Allocator>
bool operator==( const concurrent_bounded_queue<T, Allocator>& lhs,
                 const concurrent_bounded_queue<T, Allocator>& rhs );

```

Checks if `lhs` is equal to `rhs`, that is they have the same number of elements and `lhs` contains all elements from `rhs`.

Returns: true if `lhs` is equal to `rhs`; false, otherwise.

```
template <typename T, typename Allocator>
bool operator!=( const concurrent_bounded_queue<T, Allocator>& lhs,
                 const concurrent_bounded_queue<T, Allocator>& rhs );
```

Equivalent to `!(lhs == rhs)`.

Returns: true if lhs is not equal to rhs; false, otherwise.

Other

Deduction guides

If possible, `concurrent_bounded_queue` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guide is provided:

```
template <typename InputIterator,
          typename Allocator = tbb::cache_aligned_allocator<iterator_value_t
↪<InputIterator>>
concurrent_bounded_queue( InputIterator, InputIterator,
                          Allocator = Allocator() )
-> concurrent_bounded_queue<iterator_value_t<InputIterator>,
                          Allocator>;
```

Where the type alias `iterator_value_t` is defined as follows:

```
template <typename InputIterator>
using iterator_value_t = typename std::iterator_traits<InputIterator>::value_type;
```

This deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.

Example

```
#include <oneapi/tbb/concurrent_queue.h>
#include <vector>
#include <memory>

int main() {
    std::vector<int> vec;

    // Deduces cq1 as oneapi::tbb::concurrent_bounded_queue<int>
    oneapi::tbb::concurrent_bounded_queue cq1(vec.begin(), vec.end());

    // Deduces cq2 as oneapi::tbb::concurrent_bounded_queue<int, std::allocator<int>>
    oneapi::tbb::concurrent_bounded_queue cq2(vec.begin(), vec.end(), std::allocator<int>)
↪{}}
}
```

concurrent_priority_queue

[containers.concurrent_priority_queue]

oneapi::tbb::concurrent_priority_queue is a class template for an unbounded priority queue that permits multiple threads to concurrently push and pop items. Items are popped in a priority order.

Class Template Synopsis

```

namespace oneapi {
    namespace tbb {

        template <typename T, typename Compare = std::less<T>,
                 typename Allocator = cache_aligned_allocator<T>>
        class concurrent_priority_queue {
        public:
            using value_type = T;
            using reference = T&;
            using const_reference = const T&;
            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;
            using allocator_type = Allocator;

            concurrent_priority_queue();
            explicit concurrent_priority_queue( const allocator_type& alloc );

            explicit concurrent_priority_queue( const Compare& compare,
                                               const allocator_type& alloc = allocator_
↳type() );

            explicit concurrent_priority_queue( size_type init_capacity, const allocator_
↳type& alloc = allocator_type() );

            explicit concurrent_priority_queue( size_type init_capacity, const Compare&
↳compare,
                                               const allocator_type& alloc = allocator_
↳type() );

            template <typename InputIterator>
            concurrent_priority_queue( InputIterator first, InputIterator last,
                                       const allocator_type& alloc = allocator_type() );

            template <typename InputIterator>
            concurrent_priority_queue( InputIterator first, InputIterator last,
                                       const Compare& compare, const allocator_type&
↳alloc = allocator_type() );

            concurrent_priority_queue( std::initializer_list<value_type> init,
                                       const allocator_type& alloc = allocator_type() );

            concurrent_priority_queue( std::initializer_list<value_type> init,
                                       const Compare& compare, const allocator_type&
↳alloc = allocator_type() );

```

(continues on next page)

(continued from previous page)

```

        concurrent_priority_queue( const concurrent_priority_queue& other );
        concurrent_priority_queue( const concurrent_priority_queue& other, const_
↪allocator_type& alloc );

        concurrent_priority_queue( concurrent_priority_queue&& other );
        concurrent_priority_queue( concurrent_priority_queue&& other, const_
↪allocator_type& alloc );

        ~concurrent_priority_queue();

        concurrent_priority_queue& operator=( const concurrent_priority_queue& other_
↪);
        concurrent_priority_queue& operator=( concurrent_priority_queue&& other );
        concurrent_priority_queue& operator=( std::initializer_list<value_type> init_
↪);

        template <typename InputIterator>
        void assign( InputIterator first, InputIterator last );

        void assign( std::initializer_list<value_type> init );

        void swap( concurrent_priority_queue& other );

        allocator_type get_allocator() const;

        void clear();

        bool empty() const;
        size_type size() const;

        void push( const value_type& value );
        void push( value_type&& value );

        template <typename... Args>
        void emplace( Args&&... args );

        bool try_pop( value_type& value );
}; // class concurrent_priority_queue

}; // namespace tbb
} // namespace oneapi

```

Requirements:

- The type T must meet the Erasable requirements from [container.requirements] ISO C++ Standard section. Member functions can impose stricter requirements depending on the type of the operation.
- The type Compare must meet the Compare requirements from [alg.sorting] ISO C++ Standard section.
- The type Allocator must meet the Allocator requirements from [allocator.requirements] ISO C++ Standard section.

Member functions

Construction, destruction, copying

Empty container constructors

```
concurrent_priority_queue();

explicit concurrent_priority_queue( const allocator_type& alloc );

explicit concurrent_priority_queue( const Compare& compare, const allocator_
→type& alloc );
```

Constructs an empty `concurrent_priority_queue`. The initial capacity is unspecified. If provided, uses the predicate `compare` for priority comparisons and the allocator `alloc` to allocate the memory.

```
concurrent_priority_queue( size_type init_capacity,
                          const allocator_type& alloc = allocator_type() );

concurrent_priority_queue( size_type init_capacity,
                          const Compare& compare,
                          const allocator_type& alloc = allocator_type() );
```

Constructs an empty `concurrent_priority_queue` with the initial capacity `init_capacity`. If provided, uses the predicate `compare` for priority comparisons and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```
template <typename InputIterator>
concurrent_priority_queue( InputIterator first, InputIterator last,
                          const allocator_type& alloc = allocator_type() );

template <typename InputIterator>
concurrent_priority_queue( InputIterator first, InputIterator last,
                          const Compare& compare,
                          const allocator_type& alloc = allocator_type() );
```

Constructs a `concurrent_priority_queue` containing all elements from the half-open interval `[first, last)`.

If provided, uses the predicate `compare` for priority comparisons and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the *InputIterator* requirements from the [input.iterators] ISO C++ Standard section.

```
concurrent_priority_queue( std::initializer_list<value_type> init,
                          const allocator_type& alloc = allocator_type() );
```

Equivalent to `concurrent_priority_queue(init.begin(), init.end(), alloc)`.

```
concurrent_priority_queue( std::initializer_list<value_type> init,
                           const Compare& compare,
                           const allocator_type& alloc = allocator_type() );
```

Equivalent to `concurrent_priority_queue(init.begin(), init.end(), compare, alloc)`.

Copying constructors

```
concurrent_priority_queue( const concurrent_priority_queue& other );

concurrent_priority_queue( const concurrent_priority_queue& other,
                           const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by `std::allocator_traits<allocator_type>::select_on_container_get_allocator()`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_priority_queue( concurrent_priority_queue&& other );

concurrent_priority_queue( concurrent_priority_queue&& other,
                           const allocator_type& alloc );
```

Constructs a copy of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_priority_queue();
```

Destroys the `concurrent_priority_queue`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_priority_queue& operator=( const concurrent_priority_queue& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_priority_queue& operator=( concurrent_priority_queue&& other );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_priority_queue& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

assign

```
template <typename InputIterator>
void assign( InputIterator first, InputIterator last );
```

Replaces all elements in `*this` by the elements in the half-open interval `[first, last)`.

The behavior is undefined in case of concurrent operations with `*this`.

Requirements: the type `InputIterator` must meet the *InputIterator* requirements from the [input.iterators] ISO C++ Standard section.

```
void assign( std::initializer_list<value_type> init );
```

Equivalent to `assign(init.begin(), init.end())`.

Size and capacity

empty

```
bool empty() const;
```

Returns: true if the container is empty; false, otherwise.

The result may differ from the actual container state in case of pending concurrent push or try_pop operations.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ from the actual number of elements in case of pending concurrent push or try_pop operations.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other.

Pushing elements

```
void push( const value_type& value );
```

Pushes a copy of value into the container.

Requirements: the type T must meet the CopyInsertable requirements from [container.requirements] and the CopyAssignable requirements from [copyassignable] ISO C++ Standard sections.

```
void push( value_type&& value );
```

Pushes value into the container using move semantics.

Requirements: the type T must meet the MoveInsertable requirements from [container.requirements] and the MoveAssignable requirements from [moveassignable] ISO C++ Standard sections.

value is left in a valid, but unspecified state.

```
template <typename... Args>
void emplace( Args&&... args );
```

Pushes a new element constructed from args into the container.

Requirements: the type T must meet the EmplaceConstructible requirements from [container.requirements] and the MoveAssignable requirements from [moveassignable] ISO C++ Standard sections.

Popping elements

```
bool try_pop( value_type& value )
```

If the container is empty, does nothing.

Otherwise, copies the highest priority element from the container and assigns it to `value`. The popped element is destroyed.

Requirements: the type `T` must meet the `MoveAssignable` requirements from the [moveassignable] ISO C++ Standard section.

Returns: `true` if the element was popped; `false`, otherwise.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these methods with other (either concurrently safe) methods.

clear

```
void clear();
```

Removes all elements from the container.

swap

```
void swap( concurrent_priority_queue& other );
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is `true`.

Otherwise if `get_allocator() != other.get_allocator()` the behavior is undefined.

Non-member functions

These functions provides binary comparison and swap operations on `oneapi::tbb::concurrent_priority_queue` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_priority_queue` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```
template <typename T, typename Compare, typename Allocator>
void swap( concurrent_priority_queue<T, Compare, Allocator>& lhs,
           concurrent_priority_queue<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
```

(continues on next page)

(continued from previous page)

```

bool operator==( const concurrent_priority_queue<T, Compare, Allocator>& lhs,
                  const concurrent_priority_queue<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_priority_queue<T, Compare, Allocator>& lhs,
                  const concurrent_priority_queue<T, Compare, Allocator>& rhs );

```

Non-member swap

```

template <typename T, typename Compare, typename Allocator>
void swap( concurrent_priority_queue<T, Compare, Allocator>& lhs,
            concurrent_priority_queue<T, Compare, Allocator>& rhs );

```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

```

template <typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_priority_queue<T, Compare, Allocator>& lhs,
                  const concurrent_priority_queue<T, Compare, Allocator>& rhs );

```

Checks if `lhs` is equal to `rhs`, that is they have the same number of elements and `lhs` contains all elements from `rhs` with the same priority.

Returns: true if `lhs` is equal to `rhs`; false, otherwise.

```

template <typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_priority_queue<T, Compare, Allocator>& lhs,
                  const concurrent_priority_queue<T, Compare, Allocator>& rhs );

```

Equivalent to `!(lhs == rhs)`.

Returns: true if `lhs` is not equal to `rhs`; false, otherwise.

Other

Deduction guides

If possible, `oneapi::tbb::concurrent_priority_queue` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```

template <typename InputIterator,
          typename Compare = std::less<iterator_value_t<InputIterator>>,
          typename Allocator = tbb::cache_aligned_allocator<iterator_value_t
↪<InputIterator>>>
concurrent_priority_queue( InputIterator, InputIterator,
                           Compare = Compare(),
                           Allocator = Allocator() )

```

(continues on next page)

(continued from previous page)

```

-> concurrent_priority_queue<iterator_value_t<InputIterator>,
                             Compare,
                             Allocator>;

template <typename InputIterator,
          typename Allocator>
concurrent_priority_queue( InputIterator, InputIterator,
                          Allocator )
-> concurrent_priority_queue<iterator_value_t<InputIterator>,
                             std::less<iterator_value_t<InputIterator>>,
                             Allocator>;

template <typename T,
          typename Compare = std::less<T>,
          typename Allocator = tbb::cache_aligned_allocator<T>>
concurrent_priority_queue( std::initializer_list<T>,
                          Compare = Compare(),
                          Allocator = Allocator() )
-> concurrent_priority_queue<T,
                             Compare,
                             Allocator>;

template <typename T,
          typename Allocator>
concurrent_priority_queue( std::initializer_list<T>,
                          Allocator )
-> concurrent_priority_queue<T,
                             std::less<T>,
                             Allocator>;

```

Where the type alias `iterator_value_t` is defined as follows:

```

template <typename InputIterator>
using iterator_value_t = typename std::iterator_traits<InputIterator>::value_type;

```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `Compare` type does not meet the `Allocator` requirements.

Example

```

#include <oneapi/tbb/concurrent_priority_queue.h>
#include <vector>
#include <functional>

int main() {
    std::vector<int> vec;

```

(continues on next page)

(continued from previous page)

```

// Deduces cpq1 as oneapi::tbb::concurrent_priority_queue<int>
oneapi::tbb::concurrent_priority_queue cpq1(vec.begin(), vec.end());

// Deduces cpq2 as oneapi::tbb::concurrent_priority_queue<int, std::greater>
oneapi::tbb::concurrent_priority_queue cpq2(vec.begin(), vec.end(), std::greater{});
}

```

Unordered associative containers

concurrent_hash_map

[containers.concurrent_hash_map]

`concurrent_hash_map` is a class template for an unordered associative container that holds key-value pairs with unique keys and supports concurrent insertion, lookup, and erasure.

Class Template Synopsis

```

// Defined in header <oneapi/tbb/concurrent_hash_map.h>

namespace oneapi {
    namespace tbb {

        template <typename Key, typename T,
                 typename HashCompare = tbb_hash_compare<Key>,
                 typename Allocator = tbb_allocator<std::pair<const Key, T>>>
        class concurrent_hash_map {
        public:
            using key_type = Key;
            using mapped_type = T;
            using value_type = std::pair<const Key, T>;

            using reference = value_type&;
            using const_reference = const value_type&;
            using pointer = typename std::allocator_traits<Allocator>
↳::pointer;
            using const_pointer = typename std::allocator_traits<Allocator>
↳::const_pointer;

            using hash_compare_type = HashCompare;
            using allocator_type = Allocator;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer_
↳type>;

            using iterator = <implementation-defined ForwardIterator>;
            using const_iterator = <implementation-defined constant_
↳ForwardIterator>;

```

(continues on next page)

(continued from previous page)

```

using range_type = <implementation-defined ContainerRange>;
using const_range_type = <implementation-defined constant_
↳ContainerRange>;

class accessor;
class const_accessor;

// Construction, destruction, copying
concurrent_hash_map();

explicit concurrent_hash_map( const hash_compare_type& compare,
↳allocator_type() );

explicit concurrent_hash_map( const allocator_type& alloc );

concurrent_hash_map( size_type n, const hash_compare_type&
↳compare,

(continued from previous page)

```

    } // namespace tbb
} // namespace oneapi

```

Requirements:

- The expression `std::allocator_type<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of type `value_type`, must be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `HashCompare` must meet the *HashCompare requirements*.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Member classes

accessor and const_accessor

Member classes `concurrent_hash_map::accessor` and `concurrent_hash_map::const_accessor` are called *accessors*. Accessors allow multiple threads to concurrently access the key-value pairs in `concurrent_hash_map`. An accessor is called *empty* if it does not point to any item.

accessor member class

Member class `concurrent_hash_map::accessor` provides read-write access to the key-value pair in `concurrent_hash_map`.

```

namespace oneapi {
    namespace tbb {

        template <typename Key, typename T, typename HashCompare, typename Allocator>
        class concurrent_hash_map<Key, T, HashCompare, Allocator>::accessor {
            using value_type = std::pair<const Key, T>;

            accessor();
            ~accessor();

            bool empty() const;
            value_type& operator*() const;
            value_type* operator->() const;

            void release();
        }; // class accessor

    } // namespace tbb
} // namespace oneapi

```

const_accessor member class

Member class `concurrent_hash_map::const_accessor` provides read only access to the key-value pair in `concurrent_hash_map`.

```
namespace oneapi {
    namespace tbb {

        template <typename Key, typename T, typename HashCompare, typename Allocator>
        class concurrent_hash_map<Key, T, HashCompare, Allocator>::const_accessor {
            using value_type = const std::pair<const Key, T>;

            const_accessor();
            ~const_accessor();

            bool empty() const;
            value_type& operator*() const;
            value_type* operator->() const;

            void release();
        }; // class const_accessor

    } // namespace tbb
} // namespace oneapi
```

Member functions**Construction and destruction**

```
accessor();
const_accessor();
```

Constructs an empty accessor.

```
~accessor();
~const_accessor();
```

Destroys the accessor. If `*this` is not empty, releases the ownership of the element.

Emptiness

```
bool empty() const;
```

Returns: true if the accessor is empty; false, otherwise.

Key-value pair access

```
value_type& operator*() const;
```

Returns: a reference to the key-value pair to which the accessor points.

The behavior is undefined if the accessor is empty.

```
value_type* operator->() const;
```

Returns: a pointer to the key-value pair to which the accessor points.

The behavior is undefined if the accessor is empty.

Releasing

```
void release();
```

If `*this` is not empty, releases the ownership of the element. `*this` becomes empty.

Member functions

Construction, destruction, copying

Empty container constructors

```
concurrent_hash_map();

explicit concurrent_hash_map( const hash_compare_type& compare,
                             const allocator_type& alloc = allocator_type() );

explicit concurrent_hash_map( const allocator_type& alloc );
```

Constructs an empty `concurrent_hash_map`. The initial number of buckets is unspecified.

If provided, uses the comparator `compare` to calculate hash codes and compare `key_type` objects for equality and the allocator `alloc` to allocate the memory.

```

concurrent_hash_map( size_type n, const hash_compare_type& compare,
                    const allocator_type& alloc = allocator_type() );

concurrent_hash_map( size_type n, const allocator_type& alloc = allocator_
→type() );

```

Constructs an empty `concurrent_hash_map` with `n` preallocated buckets.

If provided, uses the comparator `compare` to calculate hash codes and compare `key_type` objects for equality and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```

template <typename InputIterator>
concurrent_hash_map( InputIterator first, InputIterator last,
                    const hash_compare_type& compare,
                    const allocator_type& alloc = allocator_type() );

template <typename InputIterator>
concurrent_hash_map( InputIterator first, InputIterator last,
                    const allocator_type& alloc = allocator_type() );

```

Constructs the `concurrent_hash_map` which contains the elements from the half-open interval `[first, last)`.

If the range `[first, last)` contains multiple elements with equal keys, it is unspecified which element would be inserted.

If provided, uses the comparator `compare` to calculate hash codes and compare `key_type` objects for equality and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of `InputIterator` from the `[input.iterators]` ISO C++ Standard section.

```

concurrent_hash_map( std::initializer_list<value_type> init,
                    const hash_compare_type& compare = hash_compare_type(),
                    const allocator_type& alloc = allocator_type() );

```

Equivalent to `concurrent_hash_map(init.begin(), init.end(), compare, alloc)`.

```

concurrent_hash_map( std::initializer_list<value_type> init,
                    const allocator_type& alloc );

```

Equivalent to `concurrent_hash_map(init.begin(), init.end(), alloc)`.

Copying constructors

```
concurrent_hash_map( const concurrent_hash_map& other );

concurrent_hash_map( const concurrent_hash_map& other,
                    const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_hash_map( concurrent_hash_map&& other );

concurrent_hash_map( concurrent_hash_map&& other,
                    const allocator_type& alloc );
```

Constructs a `concurrent_hash_map` with the content of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_hash_map();
```

Destroys the `concurrent_hash_map`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_hash_map& operator=( const concurrent_hash_map& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_hash_map& operator=( concurrent_hash_map&& other );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_hash_map& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

If `init` contains multiple elements with equal keys, it is unspecified which element is inserted.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with `*this`.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

clear

```
void clear();
```

Removes all elements from the container.

swap

```
void swap( concurrent_hash_map& other );
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Hash policy

Rehashing

```
void rehash( size_type n = 0 );
```

If $n > 0$, sets the number of buckets to the value that is not less than n .

bucket_count

```
size_type bucket_count() const;
```

Returns: the number of buckets in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: true if the container is empty; false, otherwise.

The result may differ with the actual container state in case of pending concurrent insertions or erasures.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ with the actual container state in case of pending concurrent insertions or erasures.

max_size

```
size_type max_size() const;
```

Returns: The maximum number of elements that container can hold.

Lookup

All methods in this section can be executed concurrently with each other and concurrently-safe modifiers.

find

```
bool find( const_accessor& result, const key_type& key ) const;

bool find( accessor& result, const key_type& key );
```

If the `result` accessor is not empty, releases the result.

If an element with the key that is equivalent to `key` exists, sets the `result` to provide access to this element.

Returns: `true` if an element with the key equivalent to `key` is found; `false` otherwise.

```
template <typename K>
bool find( const_accessor& result, const K& key ) const;

template <typename K>
bool find( accessor& result, const K& key );
```

If the `result` accessor is not empty, releases the result.

If an element with the key that compares equivalent to the value `key` exists, sets the `result` to provide access to this element.

Returns: `true` if an element with the key that compares equivalent to the value `key` is found; `false` otherwise.

This overload only participates in the overload resolution if `qualified-id hash_compare_type::is_transparent` is valid and denotes a type.

count

```
size_type count( const key_type& key ) const;
```

Returns: 1 if an element with the key equivalent to `key` exists; 0 otherwise.

```
template <typename K>
size_type count( const K& key ) const;
```

Returns: 1 if an element with the key that compares equivalent to the value `key` exists; 0 otherwise.

This overload only participates in the overload resolution if `qualified-id hash_compare_type::is_transparent` is valid and denotes a type.

Concurrently safe modifiers

All methods in this section can be executed concurrently with each other and lookup methods.

Inserting values

```
bool insert( const_accessor& result, const key_type& key );
bool insert( accessor& result, const key_type& key );
```

If the `result` accessor is not empty, releases the `result` and attempts to insert the value constructed from `key`, `mapped_type()` into the container.

Sets the `result` to provide access to the inserted element or to the element with equal key, which was already presented in the container.

Requirements:

- the `value_type` type must meet the `EmplaceConstructible` requirements described in the [container.requirements] section of the ISO C++ Standard.
- the `mapped_type` type must meet the `DefaultConstructible` requirements described in the [defaultconstructible] section of the ISO C++ Standard.

Returns: true if an element is inserted; false otherwise.

```
template <typename K>
bool insert( const_accessor& result, const K& key );

template <typename K>
bool insert( accessor& result, const K& key );
```

If the `result` accessor is not empty, releases the `result` and attempts to insert the value constructed from `key`, `mapped_type()` into the container.

Sets the `result` to provide access to the inserted element or to the element with the key, that compares equivalent to the value `key`, which was already presented in the container.

This overload only participates in the overload resolution if:

- `qualified-id hash_compare_type::is_transparent` is valid and denotes a type
- `std::is_constructible<key_type, const K&>::value` is true

Requirements: the `mapped_type` type must meet the `DefaultConstructible` requirements described in the [defaultconstructible] section of the ISO C++ Standard.

Returns: true if an element is inserted; false otherwise.

```
bool insert( const_accessor& result, const value_type& value );
bool insert( accessor& result, const value_type& value );
```

If the `result` accessor is not empty, releases the `result` and attempts to insert the value `value` into the container.

Sets the `result` to provide access to the inserted element or to the element with equal key, which was already presented in the container.

Requirements: the `value_type` type must meet the `CopyInsertable` requirements described in the [container.requirements] section of the ISO C++ Standard.

Returns: `true` if an element is inserted; `false` otherwise.

```
bool insert( const value_type& value );
```

Attempts to insert the value `value` into the container.

Requirements: the `value_type` type must meet the `CopyInsertable` requirements described in the [container.requirements] section of the ISO C++ Standard.

Returns: `true` if an element is inserted; `false` otherwise.

```
bool insert( const_accessor& result, value_type&& value );
```

```
bool insert( accessor& result, value_type&& value );
```

If the `result` accessor is not empty, releases the `result` and attempts to insert the value `value` into the container using move semantics.

Sets the `result` to provide access to the inserted element or to the element with equal key, which was already presented in the container.

`value` is left in a valid, but unspecified state.

Requirements: the `value_type` type must meet the `MoveInsertable` requirements described in the [container.requirements] section of the ISO C++ Standard.

Returns: `true` if an element is inserted; `false` otherwise.

```
bool insert( value_type&& value );
```

Attempts to insert the value `value` into the container using move semantics.

Requirements: the `value_type` type must meet the `MoveInsertable` requirements described in the [container.requirements] section of the ISO C++ Standard.

Returns: `true` if an element is inserted; `false` otherwise.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last );
```

Attempts to insert all items from the half-open interval [`first`, `last`) into the container.

If the interval [`first`, `last`) contains multiple elements with equal keys, it is unspecified which element should be inserted.

Requirements: the `InputIterator` type must meet the requirements of *InputIterator* described in the [input.iterators] section of the ISO C++ Standard.

```
void insert( std::initializer_list<value_type> init );
```

Equivalent to `insert(init.begin(), init.end())`.

Emplacing elements

```
template <typename... Args>
bool emplace( const_accessor& result, Args&&... args );

template <typename... Args>
bool emplace( accessor& result, Args&&... args );
```

If the `result` accessor is not empty, releases the `result` and attempts to insert an element constructed in-place from `args` into the container.

Sets the `result` to provide access to the inserted element or to the element with equal key, which was already presented in the container.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements described in the [container.requirements] section of the ISO C++ Standard.

Returns: `true` if an element is inserted; `false` otherwise

```
template <typename... Args>
bool emplace( Args&&... args );
```

Attempts to insert an element constructed in-place from `args` into the container.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements described in the [container.requirements] section of the ISO C++ Standard.

Returns: `true` if an element is inserted; `false` otherwise

Erasing elements

```
bool erase( const key_type& key );
```

If an element with the key equivalent to `key` exists, removes it from the container.

Returns: `true` if an element is removed; `false` otherwise.

```
template <typename K>
bool erase( const K& key );
```

If an element with the key that compares equivalent to the value `key` exists, removes it from the container.

This overload only participates in the overload resolution if `qualified-id hash_compare_type::is_transparent` is valid and denotes a type.

Returns: `true` if an element is removed; `false` otherwise.

```
bool erase( const_accessor& item_accessor );
bool erase( accessor& item_accessor );
```

Removes an element owned by `item_accessor` from the container.

Requirements: `item_accessor` should not be empty.

Returns: `true` if an element is removed by the current thread; `false` if it is removed by another thread.

Iterators

The types `concurrent_hash_map::iterator` and `concurrent_hash_map::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

begin and cbegin

```
iterator begin();
const_iterator begin() const;
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();
const_iterator end() const;
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );
std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↳const;
```

Returns: a range containing an element that is equivalent to `key`. If there is no such element in the container, returns `{end(), end()}`.

```

template <typename K>
std::pair<iterator, iterator> equal_range( const K& key );

template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key ) const;

```

Returns: a range containing an element which compares equivalent to the value key. If there is no such element in the container, returns {end(), end()}.

This overload only participates in the overload resolution if qualified-id `hash_compare_type::is_transparent` is valid and denotes a type.

Parallel iteration

Member types `concurrent_hash_map::range_type` and `concurrent_hash_map::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_hash_map::const_range_type` are of type `concurrent_hash_map::const_iterator`, whereas the bounds for a `concurrent_hash_map::range_type` are of type `concurrent_hash_map::iterator`.

Traversing the `concurrent_hash_map` is not thread safe. The behavior is undefined in case of concurrent execution of any member functions while traversing the `range_type` or `const_range_type`.

range member function

```

range_type range( std::size_t grainsize = 1 );

const_range_type range( std::size_t grainsize = 1 ) const;

```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provide binary comparison and swap operations on `oneapi::tbb::concurrent_hash_map` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_hash_map` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```

template <typename Key, typename T, typename HashCompare, typename Allocator>
bool operator==( const concurrent_hash_map<Key, T, HashCompare, Allocator>& lhs,
                 const concurrent_hash_map<Key, T, HashCompare, Allocator>& rhs );

template <typename Key, typename T, typename HashCompare, typename Allocator>
bool operator!=( const concurrent_hash_map<Key, T, HashCompare, Allocator>& lhs,
                 const concurrent_hash_map<Key, T, HashCompare, Allocator>& rhs );

template <typename Key, typename T, typename HashCompare, typename Allocator>
void swap( concurrent_hash_map<Key, T, HashCompare, Allocator>& lhs,
           concurrent_hash_map<Key, T, HashCompare, Allocator>& rhs );

```

Non-member swap

```
template <typename Key, typename T, typename HashCompare, typename Allocator>
void swap( concurrent_hash_map<Key, T, HashCompare, Allocator>& lhs,
           concurrent_hash_map<Key, T, HashCompare, Allocator>& rhs );
```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two objects of `concurrent_hash_map` are equal if the following conditions are true:

- They contain equal number of elements.
- Each element from one container is also available in the other.

```
template <typename Key, typename T, typename HashCompare, typename Allocator>
bool operator==( const concurrent_hash_map<Key, T, HashCompare, Allocator>& lhs,
                 const concurrent_hash_map<Key, T, HashCompare, Allocator>& rhs );
```

Returns: true if lhs is equivalent to rhs; false, otherwise.

```
template <typename Key, typename T, typename HashCompare, typename Allocator>
bool operator!=( const concurrent_hash_map<Key, T, HashCompare, Allocator>& lhs,
                 const concurrent_hash_map<Key, T, HashCompare, Allocator>& rhs );
```

Equivalent to `!(lhs == rhs)`.

Returns: true if lhs is not equal to rhs; false, otherwise.

Other

Deduction guides

If possible, `concurrent_hash_map` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```
template <typename InputIterator,
          typename HashCompare = tbb_hash_compare<iterator_key_t<InputIterator>>,
          typename Allocator = tbb_allocator<iterator_alloc_value_t<InputIterator>>>
concurrent_hash_map( InputIterator, InputIterator,
                    HashCompare = HashCompare(),
                    Allocator = Allocator() )
-> concurrent_hash_map<iterator_key_t<InputIterator>,
                      iterator_mapped_t<InputIterator>,
                      HashCompare,
                      Allocator>;

template <typename InputIterator,
          typename Allocator>
```

(continues on next page)

(continued from previous page)

```

concurrent_hash_map( InputIterator, InputIterator, Allocator )
-> concurrent_hash_map<iterator_key_t<InputIterator>,
    iterator_mapped_t<InputIterator>,
    tbb_hash_compare<iterator_key_t<InputIterator>>,
    Allocator>;

template <typename Key, typename T,
    typename HashCompare = tbb_hash_compare<std::remove_const_t<Key>>,
    typename Allocator = tbb_allocator<std::pair<const Key, T>>>
concurrent_hash_map( std::initializer_list<std::pair<Key, T>>,
    HashCompare = HashCompare(),
    Allocator = Allocator() )
-> concurrent_hash_map<std::remove_const_t<Key>,
    T,
    HashCompare,
    Allocator>;

template <typename Key, typename T,
    typename Allocator>
concurrent_hash_map( std::initializer_list<std::pair<Key, T>>,
    Allocator )
-> concurrent_hash_map<std::remove_const_t<Key>,
    T,
    tbb_hash_compare<std::remove_const_t<Key>>,
    Allocator>;

```

Where the type aliases `iterator_key_t`, `iterator_mapped_t`, and `iterator_alloc_value_t` are defined as follows:

```

template <typename InputIterator>
using iterator_key_t = std::remove_const_t<typename std::iterator_traits<InputIterator>
    ::value_type::first_type>;

template <typename InputIterator>
using iterator_mapped_t = typename std::iterator_traits<InputIterator>::value_
    ::type::second_type;

template <typename InputIterator>
using iterator_alloc_value_t = std::pair<std::add_const_t<iterator_key_t<InputIterator>,
    iterator_mapped_t<InputIterator>>>;

```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `HashCompare` type does not meet the `Allocator` requirements.

Example

```

#include <oneapi/tbb/concurrent_hash_map.h>
#include <vector>

int main() {
    std::vector<std::pair<const int, float>> v;

    // Deduces chmap1 as oneapi::tbb::concurrent_hash_map<int, float>
    oneapi::tbb::concurrent_hash_map chmap1(v.begin(), v.end());

    std::allocator<std::pair<const int, float>> alloc;
    // Deduces chmap2 as oneapi::tbb::concurrent_hash_map<int, float,
    //                                     tbb_hash_compare<int>,
    //                                     std::allocator<std::pair<const int,
↪float>>>
    oneapi::tbb::concurrent_hash_map chmap2(v.begin(), v.end(), alloc);
}

```

concurrent_unordered_map

[containers.concurrent_unordered_map]

`oneapi::tbb::concurrent_unordered_map` is a class template that represents an unordered associative container. It stores key-value pairs with unique keys and supports concurrent insertion, lookup, and traversal, but does not support concurrent erasure.

Class Template Synopsis

```

// Defined in header <oneapi/tbb/concurrent_unordered_map.h>

namespace oneapi {
    namespace tbb {

        template <typename Key,
                 typename T,
                 typename Hash = std::hash<Key>,
                 typename KeyEqual = std::equal_to<Key>,
                 typename Allocator = tbb_allocator<std::pair<const Key, T>>>
        class concurrent_unordered_map {
        public:
            using key_type = Key;
            using mapped_type = T;
            using value_type = std::pair<const Key, T>;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using hasher = Hash;
            using key_equal = /*See below*/;

            using allocator_type = Allocator;

```

```

Requirements:

- The expression `std::allocator_type<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of type `value_type`, must be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `Hash` must meet the `Hash` requirements from the [hash] ISO C++ Standard section.
- The type `KeyEqual` must meet the `BinaryPredicate` requirements from the [algorithms.general] ISO C++ Standard section.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Description

`oneapi::tbb::concurrent_unordered_map` is an unordered associative container, which elements are organized into buckets. The value of the hash function `Hash` for a `Key` object determines the number of the bucket in which the corresponding element will be placed.

If the qualified-id `Hash::transparent_key_equal` is valid and denotes a type, the member type `concurrent_unordered_map::key_equal` is defined as the value of this qualified-id. In this case, the program is ill-formed if any of the following conditions are met:

- The template parameter `KeyEqual` is different from `std::equal_to<Key>`.
- Qualified-id `Hash::transparent_key_equal::is_transparent` is not valid or does not denote a type.

Otherwise, the member type `concurrent_unordered_map::key_equal` is defined as the value of the template parameter `KeyEqual`.

Member functions

Construction, destruction, copying

Empty container constructors

```
concurrent_unordered_map();
explicit concurrent_unordered_map( const allocator_type& alloc );
```

Constructs an empty `concurrent_unordered_map`. The initial number of buckets is unspecified.
If provided, uses the allocator `alloc` to allocate the memory.

```
explicit concurrent_unordered_map( size_type bucket_count,
                                   const hasher& hash = hasher(),
                                   const key_equal& equal = key_equal(),
                                   const allocator_type& alloc = allocator_
→type() );
concurrent_unordered_map( size_type bucket_count, const allocator_type& alloc,
→);
concurrent_unordered_map( size_type bucket_count, const hasher& hash,
                           const allocator_type& alloc );
```

Constructs an empty `concurrent_unordered_map` with `bucket_count` buckets.
If provided, uses the hash function `hasher`, predicate `equal` to compare `key_type` objects for equality, and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```

template <typename InputIterator>
concurrent_unordered_map( InputIterator first, InputIterator last,
                          size_type bucket_count = /*implementation-defined*/,
                          const hasher& hash = hasher(),
                          const key_equal& equal = key_equal(),
                          const allocator_type& alloc = allocator_type() );

template <typename InputIterator>
concurrent_unordered_map( InputIterator first, InputIterator last,
                          size_type bucket_count, const allocator_type& alloc,
                          ↪);

template <typename InputIterator>
concurrent_unordered_map( InputIterator first, InputIterator last,
                          size_type bucket_count, const hasher& hash,
                          const allocator_type& alloc );

```

Constructs the `concurrent_unordered_map` that contains the elements from the half-open interval `[first, last)`.

If the range `[first, last)` contains multiple elements with equal keys, it is unspecified which element would be inserted.

If provided, uses the hash function `hasher`, predicate `equal` to compare `key_type` objects for equality, and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of `InputIterator` from the `[input.iterators]` ISO C++ Standard section.

```

concurrent_unordered_map( std::initializer_list<value_type> init,
                          size_type bucket_count = /*implementation-defined*/,
                          const hasher& hash = hasher(),
                          const key_equal& equal = key_equal(),
                          const allocator_type& alloc = allocator_type() );

```

Equivalent to `concurrent_unordered_map(init.begin(), init.end(), bucket_count, hash, equal, alloc)`.

```

concurrent_unordered_map( std::initializer_list<value_type> init,
                          size_type bucket_count, const allocator_type& alloc,
                          ↪);

```

Equivalent to `concurrent_unordered_map(init.begin(), init.end(), bucket_count, alloc)`.

```

concurrent_unordered_map( std::initializer_list<value_type> init,
                          size_type bucket_count, const hasher& hash,
                          const allocator_type& alloc );

```

Equivalent to `concurrent_unordered_map(init.begin(), init.end(), bucket_count, hash, alloc)`.

Copying constructors

```
concurrent_unordered_map( const concurrent_unordered_map& other );
concurrent_unordered_map( const concurrent_unordered_map& other,
                          const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_unordered_map( concurrent_unordered_map&& other );
concurrent_unordered_map( concurrent_unordered_map&& other,
                          const allocator_type& alloc );
```

Constructs a `concurrent_unordered_map` with the contents of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_unordered_map();
```

Destroys the `concurrent_unordered_map`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_unordered_map& operator=( const concurrent_unordered_map& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_unordered_map& operator=( concurrent_unordered_map&& other )_
↳noexcept( /*See below*/ );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

Exceptions: `noexcept` specification:

```
noexcept( std::allocator_traits<allocator_type>::is_always_equal::value_
↳&&
          std::is_nothrow_move_assignable<hasher>::value &&
          std::is_nothrow_move_assignable<key_equal>::value )
```

```
concurrent_unordered_map& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

If `init` contains multiple elements with equal keys, it is unspecified which element would be inserted.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

Iterators

The types `concurrent_unordered_map::iterator` and `concurrent_unordered_map::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

begin and cbegin

```
iterator begin();  
const_iterator begin() const;  
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();  
const_iterator end() const;  
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: true if the container is empty; false, otherwise.

The result may differ from the actual container state in case of pending concurrent insertions.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ from the actual container size in case of pending concurrent insertions.

max_size

```
size_type max_size() const;
```

Returns: the maximum number of elements that container can hold.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other, lookup methods and while traversing the container.

Emplacing elements

```
template <typename... Args>
std::pair<iterator, bool> emplace( Args&&... args );
```

Attempts to insert an element constructed in-place from `args` into the container.

Returns: `std::pair<iterator, bool>` where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

```
template <typename... Args>
iterator emplace_hint( const_iterator hint, Args&&... args );
```

Attempts to insert an element constructed in-place from `args` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

Returns: an `iterator` to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

Inserting values

```
std::pair<iterator, bool> insert( const value_type& value );
```

Attempts to insert `value` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, const value_type& value );
```

Attempts to insert `value` into the container.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

Returns: an `iterator` to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
template <typename P>
std::pair<iterator, bool> insert( P&& value );
```

Equivalent to `emplace(std::forward<P>(value))`.

This overload only participates in overload resolution if `std::is_constructible<value_type, P&&>::value` is true.

```
template <typename P>
iterator insert( const_iterator hint, P&& value );
```

Equivalent to `emplace_hint(hint, std::forward<P>(value))`.

This overload only participates in overload resolution if `std::is_constructible<value_type, P&&>::value` is true.

```
std::pair<iterator, bool> insert( value_type&& value );
```

Attempts to insert `value` into the container using move semantics.

`value` is left in a valid, but unspecified state.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is true if insertion took place; false, otherwise.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, value_type&& other );
```

Attempts to insert `value` into the container using move semantics.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

`value` is left in a valid, but unspecified state.

Returns: an `iterator` to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last );
```

Attempts to insert all items from the half-open interval `[first, last)` into the container.

If the interval `[first, last)` contains multiple elements with equal keys, it is unspecified which element should be inserted.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from the [input.iterators] ISO C++ Standard section.

```
void insert( std::initializer_list<value_type> init );
```

Equivalent to `insert(init.begin(), init.end())`.

Inserting nodes

```
std::pair<iterator, bool> insert( node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, attempts to insert the node owned by `nh` into the container.

If the insertion fails, node handle `nh` keeps ownership of the node.

Otherwise, `nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with key equal to `nh.key()`. Boolean value is true if insertion took place; false, otherwise.

```
iterator insert( const_iterator hint, node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, attempts to insert the node owned by `nh` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

If the insertion fails, node handle `nh` keeps ownership of the node.

Otherwise, `nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: an iterator pointing to the inserted element or to an existing element with key equal to `nh.key()`.

Merging containers

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_map<Key, T, SrcHash, SrcKeyEqual, Allocator>&&
    ↪ source );
```

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_map<Key, T, SrcHash, SrcKeyEqual, Allocator>&&
    ↪ source );
```

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_multimap<Key, T, SrcHash, SrcKeyEqual,
    ↪ Allocator>& source );
```

(continues on next page)

(continued from previous page)

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_multimap<Key, T, SrcHash, SrcKeyEqual,
↳Allocator>&& source );
```

Transfers those elements from `source` which keys do not exist in the container.

In case of merging with the container with multiple elements with equal keys, it is unspecified which element would be transferred.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `get_allocator() != source.get_allocator()`.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Clearing

```
void clear();
```

Removes all elements from the container.

Erasing elements

```
iterator unsafe_erase( const_iterator pos );
iterator unsafe_erase( iterator pos );
```

Removes the element pointed to by `pos` from the container.

Invalidates all iterators and references to the removed element.

Returns: iterator that follows the removed element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
size_type unsafe_erase( const key_type& key );
```

Removes the element with the key equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

Returns: 1 if an element with the key equivalent to `key` exists; 0, otherwise.

```
template <typename K>
size_type unsafe_erase( const K& key );
```

Removes the element with the key equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

This overload only participates in overload resolution if all of the following conditions are met:

- The qualified-id `hasher::transparent_key_equal` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: 1 if an element with the key equivalent to `key` exists; 0, otherwise.

Erasing sequences

```
iterator unsafe_erase( const_iterator first, const_iterator last );
```

Removes all elements from the half-open interval `[first, last)` from the container.

Returns: iterator that follows the last removed element.

Requirements: the range `[first, last)` must be a valid subrange in `*this`.

Extracting nodes

```
node_type unsafe_extract( iterator pos );
node_type unsafe_extract( const_iterator pos );
```

Transfers ownership of the element pointed to by `pos` from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
node_type unsafe_extract( const key_type& key );
```

If an element with the key equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element or an empty node handle if an element with the key equivalent to `key` was not found.

```
template <typename K>
node_type unsafe_extract( const K& key );
```

If an element with the key equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

This overload only participates in overload resolution if all of the following conditions are met:

- The qualified-id `hasher::transparent_key_equal` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the node handle that owns the extracted element or an empty node handle if an element with the key equivalent to `key` was not found.

swap

```
void swap( concurrent_unordered_map& other ) noexcept(/*See below*/);
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Exceptions: `noexcept` specification:

```
noexcept(std::allocator_traits<allocator_type>::is_always_equal::value_
↔&&
         std::is_nothrow_swappable<hasher>::value &&
         std::is_nothrow_swappable<key_equal>::value
```

Element access

at

```
value_type& at( const key_type& key );
const value_type& at( const key_type& key ) const;
```

Returns: a reference to `item.second`, where `item` is the element with the key equivalent to `key`.

Throws: `std::out_of_range` exception if the element with the key equivalent to `key` is not presented in the container.

operator[]

```
value_type& operator[]( const key_type& key );
```

If the element with the key equivalent to `key` is not presented in the container, inserts a new element constructed in-place from `std::piecewise_construct`, `std::forward_as_tuple(key)`, `std::tuple<>()`.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

Returns: a reference to `item.second`, where `item` is the element with the key equivalent to `key`.

```
value_type& operator[]( key_type&& key );
```

If the element with the key equivalent to `key` is not presented in the container, inserts a new element constructed in-place from `std::piecewise_construct`, `std::forward_as_tuple(std::move(key))`, `std::tuple<>()`.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

Returns: a reference to `item.second` where `item` is the element with the key equivalent to `key`.

Lookup

All methods in this section can be executed concurrently with each other, concurrently-safe modifiers and while traversing the container.

count

```
size_type count( const key_type& key );
```

Returns: the number of elements with the key equivalent to `key`.

```
template <typename K>
size_type count( const K& key );
```

Returns: the number of elements with the key that is equivalent to `key`.

This overload only participates in overload resolution if `qualified-id hasher::transparent_key_equal` is valid and denotes a type.

find

```
iterator find( const key_type& key );
const_iterator find( const key_type& key ) const;
```

Returns: an iterator to the element with the key equivalent to key, or end() if no such element exists.

```
template <typename K>
iterator find( const K& key );

template <typename K>
const_iterator find( const K& key ) const;
```

Returns: an iterator to the element with the key that is equivalent to key, or end() if no such element exists.

These overloads only participate in overload resolution if qualified-id hasher::transparent_key_equal is valid and denotes a type.

contains

```
bool contains( const key_type& key ) const;
```

Returns: true if an element with the key equivalent to key exists in the container; false, otherwise.

```
template <typename K>
bool contains( const K& key ) const;
```

Returns: true if an element with the key equivalent to key exists in the container; false, otherwise.

This overload only participates in overload resolution if qualified-id hasher::transparent_key_equal is valid and denotes a type.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );
std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↳const;
```

Returns: if an element with the key equivalent to key exists, a pair of iterators {f, l}, where f is an iterator to this element, l is std::next(f). Otherwise, {end(), end()}.

```

template <typename K>
std::pair<iterator, iterator> equal_range( const K& key )

template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key )

```

Returns: if an element with the key equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to this element, `l` is `std::next(f)`. Otherwise, `{end(), end()}`.

These overloads only participate in overload resolution if `qualified-id hasher::transparent_key_equal` is valid and denotes a type.

Bucket interface

The types `concurrent_unordered_map::local_iterator` and `concurrent_unordered_map::const_local_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

Use these iterators to traverse a certain bucket.

All methods in this section can only be executed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Bucket begin and bucket end

```

local_iterator unsafe_begin( size_type n );

const_local_iterator unsafe_begin( size_type n ) const;

const_local_iterator unsafe_cbegin( size_type n ) const;

```

Returns: an iterator to the first element in the bucket number `n`.

```

local_iterator unsafe_end( size_type n );

const_local_iterator unsafe_end( size_type n ) const;

const_local_iterator unsafe_cend( size_type n ) const;

```

Returns: an iterator to the element that follows the last element in the bucket number `n`.

The number of buckets

```

size_type unsafe_bucket_count() const;

```

Returns: the number of buckets in the container.

```

size_type unsafe_max_bucket_count() const;

```

Returns: the maximum number of buckets that container can hold.

Size of the bucket

```
size_type unsafe_bucket_size( size_type n ) const;
```

Returns: the number of elements in the bucket number n.

Bucket number

```
size_type unsafe_bucket( const key_type& key ) const;
```

Returns: the number of the bucket in which the element with the key key is stored.

Hash policy

Hash policy of `concurrent_unordered_map` manages the number of buckets in the container and the allowed maximum number of elements per bucket (load factor). If the maximum load factor is exceeded, the container can automatically increase the number of buckets.

Load factor

```
float load_factor() const;
```

Returns: the average number of elements per bucket, which is `size()/unsafe_bucket_count()`.

```
float max_load_factor() const;
```

Returns: the maximum number of elements per bucket.

```
void max_load_factor( float ml );
```

Sets the maximum number of elements per bucket to ml.

Manual rehashing

```
void rehash( size_type n );
```

Sets the number of buckets to n and rehashes the container.

```
void reserve( size_type n );
```

Sets the number of buckets to the value that is needed to store n elements.

Observers

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with `*this`.

hash_function

```
hasher hash_function() const;
```

Returns: a copy of the hash function associated with `*this`.

key_eq

```
key_equal key_eq() const;
```

Returns: a copy of the key equality predicate associated with `*this`.

Parallel iteration

Member types `concurrent_unordered_map::range_type` and `concurrent_unordered_map::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_unordered_map::const_range_type` are of type `concurrent_unordered_map::const_iterator`, whereas the bounds for a `concurrent_unordered_map::range_type` are of type `concurrent_unordered_map::iterator`.

range member function

```
range_type range();
const_range_type range() const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provide binary comparison and swap operations on `oneapi::tbb::concurrent_unordered_map` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_unordered_map` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```

template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
void swap( concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& lhs,
           concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& rhs );

template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& rhs )
↔);

template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& rhs )
↔);

```

Non-member swap

```

template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
void swap( concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& lhs,
           concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& rhs )
↔noexcept(noexcept(lhs.swap(rhs)));

```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two objects of `concurrent_unordered_map` are equal if the following conditions are true:

- They contains an equal number of elements.
- Each element from the one container is also available in the other.

```

template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& rhs )
↔);

```

Returns: true if lhs is equal to rhs; false, otherwise.

```

template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator!=( const concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_map<Key, T, Hash, KeyEqual, Allocator>& rhs )
↔);

```

Equivalent to `!(lhs == rhs)`.

Returns: true if lhs is not equal to rhs; false, otherwise.

Other

Deduction guides

If possible, `concurrent_unordered_map` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```

template <typename InputIterator,
           typename Hash = std::hash<iterator_key_t<InputIterator>>,
           typename KeyEqual = std::equal_to<iterator_key_t<InputIterator>>,
           typename Allocator = tbb::tbb_allocator<iterator_alloc_value_t<InputIterator>>>
concurrent_unordered_map( InputIterator, InputIterator,
                          map_size_type = {},
                          Hash = Hash(),
                          KeyEqual = KeyEqual(),
                          Allocator = Allocator() )
-> concurrent_unordered_map<iterator_key_t<InputIterator>,
                             iterator_mapped_t<InputIterator>,
                             Hash,
                             KeyEqual,
                             Allocator>;

template <typename InputIterator,
           typename Hash,
           typename Allocator>
concurrent_unordered_map( InputIterator, InputIterator,
                          map_size_type,
                          Hash,
                          Allocator )
-> concurrent_unordered_map<iterator_key_t<InputIterator>,
                             iterator_mapped_t<InputIterator>,
                             Hash,
                             std::equal_to<iterator_key_t<InputIterator>>,
                             Allocator>;

template <typename InputIterator,
           typename Allocator>
concurrent_unordered_map( InputIterator, InputIterator,
                          map_size_type,
                          Allocator )
-> concurrent_unordered_map<iterator_key_t<InputIterator>,
                             iterator_mapped_t<InputIterator>,
                             std::hash<iterator_key_t<InputIterator>>,
                             std::equal_to<iterator_key_t<InputIterator>>,
                             Allocator>;

template <typename Key,
           typename T,
           typename Hash = std::hash<std::remove_const_t<Key>>,
           typename KeyEqual = std::equal_to<std::remove_const_t<Key>>,
           typename Allocator = tbb::tbb_allocator<std::pair<const Key, T>>>
concurrent_unordered_map( std::initializer_list<std::pair<Key, T>>,

```

(continues on next page)

(continued from previous page)

```

        map_size_type = {},
        Hash = Hash(),
        KeyEqual = KeyEqual(),
        Allocator = Allocator() )
-> concurrent_unordered_map<std::remove_const_t<Key>,
    T,
    Hash,
    KeyEqual,
    Allocator>;

template <typename Key,
    typename T,
    typename Allocator>
concurrent_unordered_map( std::initializer_list<std::pair<Key, T>>,
    map_size_type,
    Allocator )
-> concurrent_unordered_map<std::remove_const_t<Key>,
    T,
    std::hash<std::remove_const_t<Key>>,
    std::equal_to<std::remove_const_t<Key>>,
    Allocator>;

template <typename Key,
    typename T,
    typename Allocator>
concurrent_unordered_map( std::initializer_list<std::pair<Key, T>>,
    Allocator )
-> concurrent_unordered_map<std::remove_const_t<Key>,
    T,
    std::hash<std::remove_const_t<Key>>,
    std::equal_to<std::remove_const_t<Key>>,
    Allocator>;

template <typename Key,
    typename T,
    typename Hash,
    typename Allocator>
concurrent_unordered_map( std::initializer_list<std::pair<Key, T>>,
    map_size_type,
    Hash,
    Allocator )
-> concurrent_unordered_map<std::remove_const_t<Key>,
    T,
    Hash,
    std::equal_to<std::remove_const_t<Key>>,
    Allocator>;

```

Where the `map_size_type` type refers to the `size_type` member type of the deduced `concurrent_unordered_map` and the type aliases `iterator_key_t`, `iterator_mapped_t`, and `iterator_alloc_value_t` are defined as follows:

```

template <typename InputIterator>
using iterator_key_t = std::remove_const_t<typename std::iterator_traits<InputIterator>
::value_type::first_type>;

```

(continues on next page)

(continued from previous page)

```

template <typename InputIterator>
using iterator_mapped_t = typename std::iterator_traits<InputIterator>::value_
↳type::second_type;

template <typename InputIterator>
using iterator_alloc_value_t = std::pair<std::add_const_t<iterator_key_t<InputIterator>,
                                         iterator_mapped_t<InputIterator>>>;

```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `Hash` type does not meet the `Allocator` requirements.
- The `KeyEqual` type does not meet the `Allocator` requirements.

Example

```

#include <oneapi/tbb/concurrent_unordered_map.h>
#include <vector>
#include <functional>

struct CustomHasher {...};

int main() {
    std::vector<std::pair<int, float>> v;

    // Deduces m1 as concurrent_unordered_map<int, float>
    oneapi::tbb::concurrent_unordered_map m1(v.begin(), v.end());

    // Deduces m2 as concurrent_unordered_map<int, float, CustomHasher>;
    oneapi::tbb::concurrent_unordered_map m2(v.begin(), v.end(), CustomHasher{});
}

```

concurrent_unordered_multimap

[containers.concurrent_unordered_multimap]

`oneapi::tbb::concurrent_unordered_multimap` is a class template that represents an unordered associative container. It stores key-value pairs and supports concurrent insertion, lookup, and traversal, but does not support concurrent erasure. In this container, multiple elements with equal keys can be stored.

Class Template Synopsis

```
// Defined in header <oneapi/tbb/concurrent_unordered_map.h>

namespace oneapi {
    namespace tbb {
        template <typename Key,
                 typename T,
                 typename Hash = std::hash<Key>,
                 typename KeyEqual = std::equal_to<Key>,
                 typename Allocator = tbb_allocator<std::pair<const Key, T>>>
        class concurrent_unordered_multimap {
        public:
            using key_type = Key;
            using mapped_type = T;
            using value_type = std::pair<const Key, T>;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using hasher = Hash;
            using key_equal = /*See below*/;

            using allocator_type = Allocator;

            using reference = value_type&;
            using const_reference = const value_type&;

            using pointer = typename std::allocator_traits<Allocator>::pointer;
            using const_pointer = typename std::allocator_traits<Allocator>::const_
            ↪pointer;

            using iterator = <implementation-defined ForwardIterator>;
            using const_iterator = <implementation-defined constant ForwardIterator>;

            using local_iterator = <implementation-defined ForwardIterator>;
            using const_local_iterator = <implementation-defined constant_
            ↪ForwardIterator>;

            using node_type = <implementation-defined node handle>;

            using range_type = <implementation-defined ContainerRange>;
            using const_range_type = <implementation-defined constant ContainerRange>;

```

Requirements:

- The expression `std::allocator_type<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of type `value_type`, must be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `Hash` must meet the `Hash` requirements from the [hash] ISO C++ Standard section.
- The type `KeyEqual` must meet the `BinaryPredicate` requirements from the [algorithms.general] ISO C++ Standard section.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Description

`oneapi::tbb::concurrent_unordered_multimap` is an unordered associative container, which elements are organized into buckets. The value of the hash function `Hash` for a `Key` object determines the number of the bucket in which the corresponding element will be placed.

If the qualified-id `Hash::transparent_key_equal` is valid and denotes a type, the member type `concurrent_unordered_multimap::key_equal` is defined as the value of this qualified-id. In this case, the program is ill-formed if any of the following conditions are met:

- The template parameter `KeyEqual` is different from `std::equal_to<Key>`.
- Qualified-id `Hash::transparent_key_equal::is_transparent` is not valid or does not denote a type.

Otherwise, the type `concurrent_unordered_multimap::key_equal` is defined as the value of the template parameter `KeyEqual`.

Member functions**Construction, destruction, copying****Empty container constructors**

```

concurrent_unordered_multimap();

explicit concurrent_unordered_multimap( const allocator_type& alloc );

```

Constructs an empty `concurrent_unordered_multimap`. The initial number of buckets is unspecified.

If provided uses the allocator `alloc` to allocate the memory.

```

explicit concurrent_unordered_multimap( size_type bucket_count,
                                         const hasher& hash = hasher(),
                                         const key_equal& equal = key_equal(),
                                         const allocator_type& alloc =
↳allocator_type() );

concurrent_unordered_multimap( size_type bucket_count, const allocator_type&
↳alloc );

concurrent_unordered_multimap( size_type bucket_count, const hasher& hash,
                               const allocator_type& alloc );

```

Constructs an empty `concurrent_unordered_multimap` with `bucket_count` buckets.

If provided uses the hash function `hasher`, predicate `equal` to compare `key_type` objects for equality, and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```

template <typename InputIterator>
concurrent_unordered_multimap( InputIterator first, InputIterator last,
                               size_type bucket_count = /*implementation-
↳defined*/,
                               const hasher& hash = hasher(),
                               const key_equal& equal = key_equal(),
                               const allocator_type& alloc = allocator_type()
↳);

template <typename InputIterator>
concurrent_unordered_multimap( InputIterator first, InputIterator last,
                               size_type bucket_count, const allocator_type&
↳alloc );

template <typename InputIterator>
concurrent_unordered_multimap( InputIterator first, InputIterator last,
                               size_type bucket_count, const hasher& hash,
                               const allocator_type& alloc );

```

Constructs the `concurrent_unordered_multimap` that contains all elements from the half-open interval `[first, last)`.

If provided, uses the hash function `hasher`, predicate `equal` to compare `key_type` objects for equality and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of `InputIterator` from the `[input.iterators]` ISO C++ Standard section.

```

concurrent_unordered_multimap( std::initializer_list<value_type> init,
                               size_type bucket_count = /*implementation-
↪defined*/,
                               const hasher& hash = hasher(),
                               const key_equal& equal = key_equal(),
                               const allocator_type& alloc = allocator_type()
↪);

```

Equivalent to `concurrent_unordered_multimap(init.begin(), init.end(), bucket_count, hash, equal, alloc)`.

```

concurrent_unordered_multimap( std::initializer_list<value_type> init,
                               size_type bucket_count, const allocator_type&
↪alloc );

```

Equivalent to `concurrent_unordered_multimap(init.begin(), init.end(), bucket_count, alloc)`.

```

concurrent_unordered_multimap( std::initializer_list<value_type> init,
                               size_type bucket_count, const hasher& hash,
                               const allocator_type& alloc );

```

Equivalent to `concurrent_unordered_multimap(init.begin(), init.end(), bucket_count, hash, alloc)`.

Copying constructors

```

concurrent_unordered_multimap( const concurrent_unordered_multimap& other );

concurrent_unordered_multimap( const concurrent_unordered_multimap& other,
                               const allocator_type& alloc );

```

Constructs a copy of `other`.

If the `allocator` argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```

concurrent_unordered_multimap( concurrent_unordered_multimap&& other );

concurrent_unordered_multimap( concurrent_unordered_multimap&& other,
                               const allocator_type& alloc );

```

Constructs a `concurrent_unordered_multimap` with the contents of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_unordered_multimap();
```

Destroys the `concurrent_unordered_multimap`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_unordered_multimap& operator=( const concurrent_unordered_multimap&_↵
↵other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_unordered_multimap& operator=( concurrent_unordered_multimap&&_↵
↵other ) noexcept(/*See below*/);
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

Exceptions: `noexcept` specification:

```
noexcept(std::allocator_traits<allocator_type>::is_always_equal::value_↵
↵&&
        std::is_nothrow_move_assignable<hasher>::value &&
        std::is_nothrow_move_assignable<key_equal>::value)
```

```
concurrent_unordered_multimap& operator=( std::initializer_list<value_type>_↵
↵init );
```

Replaces all elements in `*this` by the elements in `init`.

If `init` contains multiple elements with equal keys, it is unspecified which element would be inserted.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

Iterators

The types `concurrent_unordered_multimap::iterator` and `concurrent_unordered_multimap::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

begin and cbegin

```
iterator begin();  
const_iterator begin() const;  
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();  
const_iterator end() const;  
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: `true` if the container is empty; `false`, otherwise.

The result may differ from the actual container state in case of pending concurrent insertions.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ from the actual container size in case of pending concurrent insertions.

max_size

```
size_type max_size() const;
```

Returns: the maximum number of elements that container can hold.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other, lookup methods and while traversing the container.

Emplacing elements

```
template <typename... Args>
std::pair<iterator, bool> emplace( Args&&... args )
```

Inserts an element constructed in-place from `args` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

```
template <typename... Args>
iterator emplace_hint( const_iterator hint, Args&&... args )
```

Inserts an element constructed in-place from `args` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

Returns: an iterator to the inserted element.

Inserting values

```
std::pair<iterator, bool> insert( const value_type& value )
```

Inserts the value `value` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

```
iterator insert( const_iterator hint, const value_type& other )
```

Inserts the value `value` into the container.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

Returns: an iterator to the inserted element.

```
template <typename P>
std::pair<iterator, bool> insert( P&& value )
```

Equivalent to `emplace(std::forward<P>(value))`.

This overload only participates in overload resolution if `std::is_constructible<value_type, P&&>::value` is true.

```
template <typename P>
iterator insert( const_iterator hint, P&& value )
```

Equivalent to `emplace_hint(hint, std::forward<P>(value))`.

This overload only participates in overload resolution if `std::is_constructible<value_type, P&&>::value` is true.

```
std::pair<iterator, bool> insert( value_type&& value )
```

Inserts the value `value` into the container using move semantics.

`value` is left in a valid, but unspecified state.

Returns: `std::pair<iterator, bool>` where `iterator` points to the inserted element. Boolean value is always true.

```
iterator insert( const_iterator hint, value_type&& other )
```

Inserts the value `value` into the container using move semantics.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

`value` is left in a valid, but unspecified state.

Returns: an iterator to the inserted element.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last )
```

Inserts all items from the half-open interval `[first, last)` into the container.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from the [input. iterators] ISO C++ Standard section.

```
void insert( std::initializer_list<value_type> init )
```

Equivalent to `insert(init.begin(), init.end())`.

Inserting nodes

```
std::pair<iterator, bool> insert( node_type&& nh )
```

If the node handle `nh` is empty, does nothing.

Otherwise, inserts the node owned by `nh` into the container.

`nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

```
iterator insert( const_iterator hint, node_type&& nh )
```

If the node handle `nh` is empty, does nothing.

Otherwise, inserts the node owned by `nh` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

`nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: an iterator pointing to the inserted element.

Merging containers

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_map<Key, T, SrcHash, SrcKeyEqual, Allocator>&&
    ↪ source );
```

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_map<Key, T, SrcHash, SrcKeyEqual, Allocator>&&
    ↪ source );
```

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_multimap<Key, T, SrcHash, SrcKeyEqual,
    ↪Allocator>& source );
```

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_multimap<Key, T, SrcHash, SrcKeyEqual,
    ↪Allocator>&& source );
```

Transfers all elements from `source` to `*this`.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `get_allocator() != source.get_allocator()`.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Clearing

```
void clear();
```

Removes all elements from the container.

Erasing elements

```
iterator unsafe_erase( const_iterator pos );  
iterator unsafe_erase( iterator pos );
```

Removes the element pointed to by `pos` from the container.

Invalidates all iterators and references to the removed element.

Returns: iterator that follows the removed element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
size_type unsafe_erase( const key_type& key );
```

Removes all elements with the key equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed elements.

Returns: the number of removed elements.

```
template <typename K>  
size_type unsafe_erase( const K& key );
```

Removes all elements with the key equivalent to `key` if they exist in the container.

Invalidates all iterators and references to the removed elements.

This overload only participates in overload resolution if all of the following statements are true:

- The qualified-id `hasher::transparent_key_equal` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the number of removed elements.

Erasing sequences

```
iterator unsafe_erase( const_iterator first, const_iterator last );
```

Removes all elements from the half-open interval `[first, last)` from the container.

Returns: iterator that follows the last removed element.

Requirements: the range `[first, last)` must be a valid subrange in `*this`.

Extracting nodes

```
node_type unsafe_extract( iterator pos );
node_type unsafe_extract( const_iterator pos );
```

Transfers ownership of the element pointed to by `pos` from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
node_type unsafe_extract( const key_type& key );
```

If at least one element with the key equivalent to `key` exists, transfers ownership of one of these element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

If there are multiple elements with the key equivalent to `key`, it is unspecified which element should be transferred.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element or an empty node handle if an element with the key equivalent to `key` was not found.

```
template <typename K>
node_type unsafe_extract( const K& key );
```

If at least one element with the key equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

If there are multiple elements with the key equivalent to `key` exists, it is unspecified which element should be transferred.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

This overload only participates in overload resolution if all of the following statements are true:

- The qualified-id `hasher::transparent_key_equal` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the node handle that owns the extracted element or an empty node handle if an element with the key equivalent to `key` was not found.

swap

```
void swap( concurrent_unordered_multimap& other ) noexcept(/*See below*/);
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Exceptions: `noexcept` specification:

```
noexcept(std::allocator_traits<allocator_type>::is_always_equal::value_
↪ &&
        std::is_nothrow_swappable<hasher>::value &&
        std::is_nothrow_swappable<key_equal>::value
```

Lookup

All methods in this section can be executed concurrently with each other, concurrently-safe modifiers and while traversing the container.

count

```
size_type count( const key_type& key );
```

Returns: the number of elements with the key equivalent to `key`.

```
template <typename K>
size_type count( const K& key );
```

Returns: the number of elements with the key equivalent to `key`.

This overload only participates in overload resolution if qualified-id `hasher::transparent_key_equal` is valid and denotes a type.

find

```
iterator find( const key_type& key );
const_iterator find( const key_type& key ) const;
```

Returns: an iterator to the element with the key equivalent to `key`, or `end()` if no such element exists.

If there are multiple elements with the key equivalent to `key`, it is unspecified which element should be found.

```
template <typename K>
iterator find( const K& key );

template <typename K>
const_iterator find( const K& key ) const;
```

Returns: an iterator to the element with the key equivalent to `key`, or `end()` if no such element exists.

If there are multiple elements with the key equivalent to `key`, it is unspecified which element should be found.

These overloads only participates in overload resolution if qualified-id `hasher::transparent_key_equal` is valid and denotes a type.

contains

```
bool contains( const key_type& key ) const;
```

Returns: true if at least one element with the key equivalent to `key` exists in the container; false, otherwise.

```
template <typename K>
bool contains( const K& key ) const;
```

Returns: true if at least one element with the key equivalent to `key` exists in the container; false, otherwise.

This overload only participates in overload resolution if qualified-id `hasher::transparent_key_equal` is valid and denotes a type.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );
std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↳ const;
```

Returns: if at least one element with the key equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to the first element with the key equivalent to `key`, `l` is an iterator to the element which follows the last element with the key equivalent to `key`. Otherwise, `{end(), end()}`.

```

template <typename K>
std::pair<iterator, iterator> equal_range( const K& key )

template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key )

```

Returns: if at least one element with the key equivalent to `key` exists - a pair of iterators `{f, l}`, where `f` is an iterator to the first element with the key equivalent to `key`, `l` is an iterator to the element that follows the last element with the key equivalent to `key`. Otherwise, `{end(), end()}`.

These overloads only participates in overload resolution if qualified-id `hasher::transparent_key_equal` is valid and denotes a type.

Bucket interface

The types `concurrent_unordered_multimap::local_iterator` and `concurrent_unordered_multimap::const_local_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

These iterators are used to traverse the certain bucket.

All methods in this section can only be executed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Bucket begin and bucket end

```

local_iterator unsafe_begin( size_type n );

const_local_iterator unsafe_begin( size_type n ) const;

const_local_iterator unsafe_cbegin( size_type n ) const;

```

Returns: an iterator to the first element in the bucket number `n`.

```

local_iterator unsafe_end( size_type n );

const_local_iterator unsafe_end( size_type n ) const;

const_local_iterator unsafe_cend( size_type n ) const;

```

Returns: an iterator to the element that follows the last element in the bucket number `n`.

The number of buckets

```
size_type unsafe_bucket_count() const;
```

Returns: the number of buckets in the container.

```
size_type unsafe_max_bucket_count() const;
```

Returns: the maximum number of buckets that container can hold.

Size of the bucket

```
size_type unsafe_bucket_size( size_type n ) const;
```

Returns: the number of elements in the bucket number n.

Bucket number

```
size_type unsafe_bucket( const key_type& key ) const;
```

Returns: the number of the bucket in which the element with the key key is stored.

Hash policy

Hash policy of `concurrent_unordered_multimap` manages the number of buckets in the container and the allowed maximum number of elements per bucket (load factor). If the maximum load factor is exceeded, the container can automatically increase the number of buckets.

Load factor

```
float load_factor() const;
```

Returns: the average number of elements per bucket, which is `size()/unsafe_bucket_count()`.

```
float max_load_factor() const;
```

Returns: the maximum number of elements per bucket.

```
void max_load_factor( float ml );
```

Sets the maximum number of elements per bucket to ml.

Manual rehashing

```
void rehash( size_type n );
```

Sets the number of buckets to `n` and rehashes the container.

```
void reserve( size_type n );
```

Sets the number of buckets to the value that is needed to store `n` elements.

Observers

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with `*this`.

hash_function

```
hasher hash_function() const;
```

Returns: a copy of the hash function associated with `*this`.

key_eq

```
key_equal key_eq() const;
```

Returns: a copy of the key equality predicate associated with `*this`.

Parallel iteration

Member types `concurrent_unordered_multimap::range_type` and `concurrent_unordered_multimap::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_unordered_multimap::const_range_type` are of type `concurrent_unordered_multimap::const_iterator`, whereas the bounds for a `concurrent_unordered_multimap::range_type` are of type `concurrent_unordered_multimap::iterator`.

range member function

```
range_type range();

const_range_type range() const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provides binary comparison and swap operations on `oneapi::tbb::concurrent_unordered_multimap` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_unordered_multimap` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```
template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
void swap( concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>& lhs,
           concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>& rhs );

template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>&
↳lhs,
                const concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>&
↳rhs );

template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>&
↳lhs,
                const concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>&
↳rhs );
```

Non-member swap

```
template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
void swap( concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>& lhs,
           concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>& rhs )
↳noexcept(noexcept(lhs.swap(rhs)));
```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two objects of `concurrent_unordered_multimap` are equal if the following conditions are true:

- They contain an equal number of elements.
- Each group of elements with the same key in one container has the corresponding group of equivalent elements in the other container (not necessary in the same order).

```
template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>&
↳ lhs,
                const concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>&
↳ rhs );
```

Returns: true if lhs is equal to rhs; false, otherwise.

```
template <typename Key, typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator!=( const concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>&
↳ lhs,
                const concurrent_unordered_multimap<Key, T, Hash, KeyEqual, Allocator>&
↳ rhs );
```

Equivalent to `!(lhs == rhs)`.

Returns: true if lhs is not equal to rhs; false, otherwise.

Other

Deduction guides

If possible, `concurrent_unordered_multimap` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```
template <typename InputIterator,
          typename Hash = std::hash<iterator_key_t<InputIterator>>,
          typename KeyEqual = std::equal_to<iterator_key_t<InputIterator>>,
          typename Allocator = tbb::tbb_allocator<iterator_alloc_value_t<InputIterator>>>
concurrent_unordered_multimap( InputIterator, InputIterator,
                              map_size_type = {},
                              Hash = Hash(),
                              KeyEqual = KeyEqual(),
                              Allocator = Allocator() )
-> concurrent_unordered_multimap<iterator_key_t<InputIterator>,
                               iterator_mapped_t<InputIterator>,
                               Hash,
                               KeyEqual,
                               Allocator>;
```

(continues on next page)

(continued from previous page)

```

template <typename InputIterator,
         typename Hash,
         typename Allocator>
concurrent_unordered_multimap( InputIterator, InputIterator,
                              map_size_type,
                              Hash,
                              Allocator )
-> concurrent_unordered_multimap<iterator_key_t<InputIterator>,
                               iterator_mapped_t<InputIterator>,
                               Hash,
                               std::equal_to<iterator_key_t<InputIterator>>,
                               Allocator>;

template <typename InputIterator,
         typename Allocator>
concurrent_unordered_multimap( InputIterator, InputIterator,
                              map_size_type,
                              Allocator )
-> concurrent_unordered_multimap<iterator_key_t<InputIterator>,
                               iterator_mapped_t<InputIterator>,
                               std::hash<iterator_key_t<InputIterator>>,
                               std::equal_to<iterator_key_t<InputIterator>>,
                               Allocator>;

template <typename Key,
         typename T,
         typename Hash = std::hash<std::remove_const_t<Key>>,
         typename KeyEqual = std::equal_to<std::remove_const_t<Key>>,
         typename Allocator = tbb::tbb_allocator<std::pair<const Key, T>>>
concurrent_unordered_multimap( std::initializer_list<std::pair<Key, T>>,
                              map_size_type = {},
                              Hash = Hash(),
                              KeyEqual = KeyEqual(),
                              Allocator = Allocator() )
-> concurrent_unordered_multimap<std::remove_const_t<Key>,
                               T,
                               Hash,
                               KeyEqual,
                               Allocator>;

template <typename Key,
         typename T,
         typename Allocator>
concurrent_unordered_multimap( std::initializer_list<std::pair<Key, T>>,
                              map_size_type,
                              Allocator )
-> concurrent_unordered_multimap<std::remove_const_t<Key>,
                               T,
                               std::hash<std::remove_const_t<Key>>,
                               std::equal_to<std::remove_const_t<Key>>,
                               Allocator>;

```

(continues on next page)

(continued from previous page)

```

template <typename Key,
         typename T,
         typename Allocator>
concurrent_unordered_multimap( std::initializer_list<std::pair<Key, T>>,
                             Allocator )
-> concurrent_unordered_multimap<std::remove_const_t<Key>,
                                T,
                                std::hash<std::remove_const_t<Key>>,
                                std::equal_to<std::remove_const_t<Key>>,
                                Allocator>;

template <typename Key,
         typename T,
         typename Hash,
         typename Allocator>
concurrent_unordered_multimap( std::initializer_list<std::pair<Key, T>>,
                              map_size_type,
                              Hash,
                              Allocator )
-> concurrent_unordered_multimap<std::remove_const_t<Key>,
                                T,
                                Hash,
                                std::equal_to<std::remove_const_t<Key>>,
                                Allocator>;

```

Where the `map_size_type` type refers to the `size_type` member type of the deduced `concurrent_unordered_multimap` and the type aliases `iterator_key_t`, `iterator_mapped_t`, and `iterator_alloc_value_t` are defined as follows:

```

template <typename InputIterator>
using iterator_key_t = std::remove_const_t<typename std::iterator_traits<InputIterator>
->::value_type::first_type>;

template <typename InputIterator>
using iterator_mapped_t = typename std::iterator_traits<InputIterator>::value_
->type::second_type;

template <typename InputIterator>
using iterator_alloc_value_t = std::pair<std::add_const_t<iterator_key_t<InputIterator>,
                                         iterator_mapped_t<InputIterator>>>;

```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `Hash` type does not meet the `Allocator` requirements.
- The `KeyEqual` type does not meet the `Allocator` requirements.

Example

```

#include <oneapi/tbb/concurrent_unordered_map.h>
#include <vector>
#include <functional>

struct CustomHasher {...};

int main() {
    std::vector<std::pair<int, float>> v;

    // Deduces m1 as concurrent_unordered_multimap<int, float>
    oneapi::tbb::concurrent_unordered_multimap m1(v.begin(), v.end());

    // Deduces m2 as concurrent_unordered_multimap<int, float, CustomHasher>;
    oneapi::tbb::concurrent_unordered_multimap m2(v.begin(), v.end(), CustomHasher{});
}

```

concurrent_unordered_set

[containers.concurrent_unordered_set]

oneapi::tbb::concurrent_unordered_set is a class template that represents an unordered sequence of unique elements. It supports concurrent insertion, lookup, and traversal, but does not support concurrent erasure.

Class Template Synopsis

```

// Defined in header <oneapi/tbb/concurrent_unordered_set.h>

namespace oneapi {
    namespace tbb {
        template <typename T,
                 typename Hash = std::hash<Key>,
                 typename KeyEqual = std::equal_to<Key>,
                 typename Allocator = tbb_allocator<std::pair<const Key, T>>>
        class concurrent_unordered_set {
        public:
            using key_type = Key;
            using value_type = Key;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using hasher = Hash;
            using key_equal = /*See below*/;

            using allocator_type = Allocator;

            using reference = value_type&;
            using const_reference = const value_type&;

            using pointer = typename std::allocator_traits<Allocator>::pointer;

```

(continues on next page)

```

Requirements:

- The expression `std::allocator_type<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of type `value_type`, must be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `Hash` must meet the `Hash` requirements from the [hash] ISO C++ Standard section.
- The type `KeyEqual` must meet the `BinaryPredicate` requirements from the [algorithms.general] ISO C++ Standard section.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Description

`oneapi::tbb::concurrent_unordered_set` is an unordered sequence, which elements are organized into buckets. The value of the hash function `Hash` for `Key` object determines the number of the bucket in which the corresponding element will be placed.

If the qualified-id `Hash::transparent_key_equal` is valid and denotes a type, the member type `concurrent_unordered_set::key_equal` is defined as the value of this qualified-id. In this case, the program is ill-formed if any of the following conditions are met:

- The template parameter `KeyEqual` is different from `std::equal_to<Key>`.
- Qualified-id `Hash::transparent_key_equal::is_transparent` is not valid or does not denote a type.

Otherwise, the member type `concurrent_unordered_set::key_equal` is defined as the value of the template parameter `KeyEqual`.

Member functions

Construction, destruction, copying

Empty container constructors

```
concurrent_unordered_set();

explicit concurrent_unordered_set( const allocator_type& alloc );
```

Constructs an empty `concurrent_unordered_set`. The initial number of buckets is unspecified. If provided, uses the allocator `alloc` to allocate the memory.

```
explicit concurrent_unordered_set( size_type bucket_count,
                                   const hasher& hash = hasher(),
                                   const key_equal& equal = key_equal(),
                                   const allocator_type& alloc = allocator_
→type() );

concurrent_unordered_set( size_type bucket_count, const allocator_type& alloc,
→);

concurrent_unordered_set( size_type bucket_count, const hasher& hash,
                           const allocator_type& alloc );
```

Constructs an empty `concurrent_unordered_set` with `bucket_count` buckets. If provided, uses the hash function `hasher`, predicate `equal` to compare `key_type` objects for equality, and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```
template <typename InputIterator>
concurrent_unordered_set( InputIterator first, InputIterator last,
                          size_type bucket_count = /*implementation-defined*/,
                          const hasher& hash = hasher(),
                          const key_equal& equal = key_equal(),
                          const allocator_type& alloc = allocator_type() );

template <typename InputIterator>
concurrent_unordered_set( InputIterator first, InputIterator last,
                          size_type bucket_count, const allocator_type& alloc,
→);

template <typename InputIterator>
concurrent_unordered_set( InputIterator first, InputIterator last,
                          size_type bucket_count, const hasher& hash,
                          const allocator_type& alloc );
```

Constructs the `concurrent_unordered_set` that contains the elements from the half-open interval `[first, last)`.

If the range `[first, last)` contains multiple equal elements, it is unspecified which element would be inserted.

If provided, uses the hash function `hasher`, predicate `equal` to compare `key_type` objects for equality, and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of `InputIterator` from the `[input.iterators]` ISO C++ Standard section.

```
concurrent_unordered_set( std::initializer_list<value_type> init,
                          size_type bucket_count = /*implementation-defined*/,
                          const hasher& hash = hasher(),
                          const key_equal& equal = key_equal(),
                          const allocator_type& alloc = allocator_type() );
```

Equivalent to `concurrent_unordered_set(init.begin(), init.end(), bucket_count, hash, equal, alloc)`.

```
concurrent_unordered_set( std::initializer_list<value_type> init,
                          size_type bucket_count, const allocator_type& alloc,
                          ↪);
```

Equivalent to `concurrent_unordered_set(init.begin(), init.end(), bucket_count, alloc)`.

```
concurrent_unordered_set( std::initializer_list<value_type> init,
                          size_type bucket_count, const hasher& hash,
                          const allocator_type& alloc );
```

Equivalent to `concurrent_unordered_set(init.begin(), init.end(), bucket_count, hash, alloc)`.

Copying constructors

```
concurrent_unordered_set( const concurrent_unordered_set& other );

concurrent_unordered_set( const concurrent_unordered_set& other,
                          const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_unordered_set( concurrent_unordered_set&& other );

concurrent_unordered_set( concurrent_unordered_set&& other,
                          const allocator_type& alloc );
```

Constructs a *concurrent_unordered_set* with the contents of *other* using move semantics.

other is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with *other*.

Destructor

```
~concurrent_unordered_set();
```

Destroys the *concurrent_unordered_set*. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with **this*.

Assignment operators

```
concurrent_unordered_set& operator=( const concurrent_unordered_set& other );
```

Replaces all elements in **this* by the copies of the elements in *other*.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::is true`.

The behavior is undefined in case of concurrent operations with **this* and *other*.

Returns: a reference to **this*.

```
concurrent_unordered_set& operator=( concurrent_unordered_set&& other )_
↳noexcept( /*See below*/ );
```

Replaces all elements in **this* by the elements in *other* using move semantics.

other is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::is true`.

The behavior is undefined in case of concurrent operations with **this* and *other*.

Returns: a reference to **this*.

Exceptions: `noexcept` specification:

```
noexcept(std::allocator_traits<allocator_type>::is_always_equal::value_
↪&&
        std::is_nothrow_move_assignable<hasher>::value &&
        std::is_nothrow_move_assignable<key_equal>::value)
```

```
concurrent_unordered_set& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in *this by the elements in init.

If init contains multiple equal elements, it is unspecified which element would be inserted.

The behavior is undefined in case of concurrent operations with *this.

Returns: a reference to *this.

Iterators

The types `concurrent_unordered_set::iterator` and `concurrent_unordered_set::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

begin and cbegin

```
iterator begin();
const_iterator begin() const;
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();
const_iterator end() const;
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: true if the container is empty; false, otherwise.

The result may differ from the actual container state in case of pending concurrent insertions.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ from the actual container size in case of pending concurrent insertions.

max_size

```
size_type max_size() const;
```

Returns: the maximum number of elements that container can hold.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other, lookup methods and while traversing the container.

Inserting values

```
std::pair<iterator, bool> insert( const value_type& value );
```

Attempts to insert the value `value` into the container.

Returns: `std::pair<iterator, bool>` where `iterator` points to the inserted element or to an existing equal element. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, const value_type& other );
```

Attempts to insert the value `value` into the container.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

Returns: an `iterator` to the inserted element or to an existing equal element.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
std::pair<iterator, bool> insert( value_type&& value );
```

Attempts to insert the value `value` into the container using move semantics.

`value` is left in a valid, but unspecified state.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing equal element. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, value_type&& other );
```

Attempts to insert the value `value` into the container using move semantics.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

`value` is left in a valid, but unspecified state.

Returns: an iterator to the inserted element or to an existing equal element.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last );
```

Attempts to insert all items from the half-open interval `[first, last)` into the container.

If the interval `[first, last)` contains multiple equal elements, it is unspecified which element should be inserted.

Requirements: the type `InputIterator` must meet the requirements of `InputIterator` from [input.iterators] ISO C++ Standard section.

```
void insert( std::initializer_list<value_type> init );
```

Equivalent to `insert(init.begin(), init.end())`.

Inserting nodes

```
std::pair<iterator, bool> insert( node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, attempts to insert the node owned by `nh` into the container.

If the insertion fails, node handle `nh` keeps ownership of the node.

Otherwise, `nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element equal to `nh.value()`. Boolean value is `true` if insertion took place; `false`, otherwise.

```
iterator insert( const_iterator hint, node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, attempts to insert the node owned by `nh` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

If the insertion fails, node handle `nh` keeps ownership of the node.

Otherwise, `nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: an iterator pointing to the inserted element or to an existing element equal to `nh.value()`.

Emplacing elements

```
template <typename... Args>
std::pair<iterator, bool> emplace( Args&&... args );
```

Attempts to insert an element constructed in-place from `args` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing equal element. Boolean value is `true` if insertion took place, `false` otherwise.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

```
template <typename... Args>
iterator emplace_hint( const_iterator hint, Args&&... args );
```

Attempts to insert an element constructed in-place from `args` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

Returns: an iterator to the inserted element or to an existing equal element.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ Standard section.

Merging containers

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_set<T, SrcHash, SrcKeyEqual, Allocator>&&
↳source );

template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_set<T, SrcHash, SrcKeyEqual, Allocator>&&
↳source );

template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_multiset<T, SrcHash, SrcKeyEqual, Allocator>&&
↳source );
```

(continues on next page)

(continued from previous page)

```
template <typename SrcHash, typename SrcKeyEqual>
void merge( concurrent_unordered_multiset<T, SrcHash, SrcKeyEqual, Allocator>&&
    → source );
```

Transfers those elements from `source` that do not exist in the container.

In case of merging with the container with multiple equal elements, it is unspecified which element would be transferred.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `get_allocator() != source.get_allocator()`.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Clearing

```
void clear();
```

Removes all elements from the container.

Erasing elements

```
iterator unsafe_erase( const_iterator pos );
iterator unsafe_erase( iterator pos );
```

Removes the element pointed to by `pos` from the container.

Invalidates all iterators and references to the removed element.

Returns: iterator that follows the removed element.

Requirements: the iterator `pos` should be valid, dereferenceable, and point to the element in `*this`.

```
size_type unsafe_erase( const key_type& key );
```

Removes the element equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

Returns: 1 if an element equivalent to `key` exists; 0, otherwise.

```
template <typename K>
size_type unsafe_erase( const K& key );
```

Removes the element equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

This overload only participates in overload resolution if all of the following statements are `true`:

- The qualified-id `hasher::transparent_key_equal` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is `false`.
- `std::is_convertible<K, const_iterator>::value` is `false`.

Returns: 1 if an element equivalent to `key` exists; 0, otherwise.

Erasing sequences

```
iterator unsafe_erase( const_iterator first, const_iterator last );
```

Removes all elements from the half-open interval `[first, last)` from the container.

Returns: iterator that follows the last removed element.

Requirements: the range `[first, last)` must be a valid subrange in `*this`.

Extracting nodes

```
node_type unsafe_extract( iterator pos );
node_type unsafe_extract( const_iterator pos );
```

Transfers ownership of the element pointed to by `pos` from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element.

Requirements: the iterator `pos` should be valid, dereferenceable, and point to the element in `*this`.

```
node_type unsafe_extract( const key_type& key );
```

If an element equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element or an empty node handle if an element equivalent to `key` was not found.

```
template <typename K>
node_type unsafe_extract( const K& key );
```

If an element equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

This overload participates in overload resolution only if all of the following statements are true:

- The qualified-id `hasher::transparent_key_equal` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the node handle that owns the extracted element or an empty node handle if an element equivalent to `key` was not found.

swap

```
void swap( concurrent_unordered_set& other ) noexcept(/*See below*/);
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Exceptions: `noexcept` specification:

```
noexcept(std::allocator_traits<allocator_type>::is_always_equal::value_
↪&&
        std::is_nothrow_swappable<hasher>::value &&
        std::is_nothrow_swappable<key_equal>::value
```

Lookup

All methods in this section can be executed concurrently with each other, concurrently-safe modifiers and while traversing the container.

count

```
size_type count( const key_type& key );
```

Returns: the number of elements equivalent to `key`.

```
template <typename K>
size_type count( const K& key );
```

Returns: the number of elements that is equivalent to key.

This overload only participates in overload resolution if `qualified-id hasher::transparent_key_equal` is valid and denotes a type.

find

```
iterator find( const key_type& key );
const_iterator find( const key_type& key ) const;
```

Returns: an iterator to the element equivalent to key, or `end()` if no such element exists.

```
template <typename K>
iterator find( const K& key );

template <typename K>
const_iterator find( const K& key ) const;
```

Returns: an iterator to the element that is equivalent to key, or `end()` if no such element exists.

These overloads only participates in overload resolution if `qualified-id hasher::transparent_key_equal` is valid and denotes a type.

contains

```
bool contains( const key_type& key ) const;
```

Returns: true if an element equivalent to key exists in the container; false, otherwise.

```
template <typename K>
bool contains( const K& key ) const;
```

Returns: true if an element equivalent to key exists in the container; false, otherwise.

This overload only participates in overload resolution if `qualified-id hasher::transparent_key_equal` is valid and denotes a type.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );

std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↳const;
```

Returns: if an element equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to this element, `l` is `std::next(f)`. Otherwise, `{end(), end()}`.

```
template <typename K>
std::pair<iterator, iterator> equal_range( const K& key )

template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key )
```

Returns: if an element equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to this element, `l` is `std::next(f)`. Otherwise, `{end(), end()}`.

These overloads participate in overload resolution only if `qualified-id hasher::transparent_key_equal` is valid and denotes a type.

Bucket interface

The types `concurrent_unordered_set::local_iterator` and `concurrent_unordered_set::const_local_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

Use these iterators to traverse the certain bucket.

All methods in this section can only be executed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Bucket begin and bucket end

```
local_iterator unsafe_begin( size_type n );

const_local_iterator unsafe_begin( size_type n ) const;

const_local_iterator unsafe_cbegin( size_type n ) const;
```

Returns: an iterator to the first element in the bucket number `n`.

```
local_iterator unsafe_end( size_type n );

const_local_iterator unsafe_end( size_type n ) const;

const_local_iterator unsafe_cend( size_type n ) const;
```

Returns: an iterator to the element that follows the last element in the bucket number `n`.

The number of buckets

```
size_type unsafe_bucket_count() const;
```

Returns: the number of buckets in the container.

```
size_type unsafe_max_bucket_count() const;
```

Returns: the maximum number of buckets that container can hold.

Size of the bucket

```
size_type unsafe_bucket_size( size_type n ) const;
```

Returns: the number of elements in the bucket number n.

Bucket number

```
size_type unsafe_bucket( const key_type& key ) const;
```

Returns: the number of the bucket in which the element with the key key is stored.

Hash policy

Hash policy of `concurrent_unordered_set` manages the number of buckets in the container and the allowed maximum number of elements per bucket (load factor). If the maximum load factor is exceeded, the container can automatically increase the number of buckets.

Load factor

```
float load_factor() const;
```

Returns: the average number of elements per bucket, which is `size()/unsafe_bucket_count()`.

```
float max_load_factor() const;
```

Returns: the maximum number of elements per bucket.

```
void max_load_factor( float ml );
```

Sets the maximum number of elements per bucket to ml.

Manual rehashing

```
void rehash( size_type n );
```

Sets the number of buckets to `n` and rehashes the container.

```
void reserve( size_type n );
```

Sets the number of buckets to the value that is needed to store `n` elements.

Observers

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with `*this`.

hash_function

```
hasher hash_function() const;
```

Returns: a copy of the hash function associated with `*this`.

key_eq

```
key_equal key_eq() const;
```

Returns: a copy of the key equality predicate associated with `*this`.

Parallel iteration

Member types `concurrent_unordered_set::range_type` and `concurrent_unordered_set::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_unordered_set::const_range_type` are of type `concurrent_unordered_set::const_iterator`, whereas the bounds for a `concurrent_unordered_set::range_type` are of type `concurrent_unordered_set::iterator`.

range member function

```
range_type range();

const_range_type range() const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provide binary comparison and swap operations on `oneapi::tbb::concurrent_unordered_set` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_unordered_set` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```
template <typename T, typename Hash,
          typename KeyEqual, typename Allocator>
void swap( concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& lhs,
           concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& rhs );

template <typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& rhs );

template <typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& rhs );
```

Non-member swap

```
template <typename T, typename Hash,
          typename KeyEqual, typename Allocator>
void swap( concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& lhs,
           concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& rhs )_
↳noexcept(noexcept(lhs.swap(rhs)));
```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two objects of `concurrent_unordered_set` are equal if the following conditions are true:

- They contain an equal number of elements.
- Each element from one container is also available in the other.

```
template <typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& rhs );
```

Returns: true if lhs is equal to rhs, false otherwise.

```
template <typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator!=( const concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_set<T, Hash, KeyEqual, Allocator>& rhs );
```

Equivalent to `!(lhs == rhs)`.

Returns: true if lhs is not equal to rhs; false, otherwise.

Other

Deduction guides

If possible, `concurrent_unordered_set` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```
template <typename InputIterator,
          typename Hash = std::hash<iterator_value_t<InputIterator>>,
          typename KeyEqual = std::equal_to<iterator_value_t<InputIterator>>,
          typename Allocator = tbb::tbb_allocator<iterator_value_t<InputIterator>>>
concurrent_unordered_set( InputIterator, InputIterator,
                          set_size_type = {},
                          Hash = Hash(),
                          KeyEqual = KeyEqual(),
                          Allocator = Allocator() )
-> concurrent_unordered_set<iterator_value_t<InputIterator>,
                           Hash,
                           KeyEqual,
                           Allocator>;

template <typename InputIterator,
          typename Allocator>
concurrent_unordered_set( InputIterator, InputIterator,
                          set_size_type,
                          Allocator )
-> concurrent_unordered_set<iterator_value_t<InputIterator>,
                           Allocator>;
```

(continues on next page)

(continued from previous page)

```

        std::hash<iterator_value_t<InputIterator>>,
        std::equal_to<iterator_value_t<InputIterator>>,
        Allocator>;

template <typename T,
         typename Hash = std::hash<T>,
         typename KeyEqual = std::equal_to<T>,
         typename Allocator = tbb::tbb_allocator<T>>
concurrent_unordered_set( std::initializer_list<T>,
                        set_size_type = {},
                        Hash = Hash(),
                        KeyEqual = KeyEqual(),
                        Allocator = Allocator() )
-> concurrent_unordered_set<T,
                          Hash,
                          KeyEqual,
                          Allocator>;

template <typename T,
         typename Allocator>
concurrent_unordered_set( std::initializer_list<T>,
                        set_size_type,
                        Allocator )
-> concurrent_unordered_set<T,
                          std::hash<T>,
                          std::equal_to<T>,
                          Allocator>;

template <typename T,
         typename Allocator>
concurrent_unordered_set( std::initializer_list<T>,
                        Allocator )
-> concurrent_unordered_set<T,
                          std::hash<T>,
                          std::equal_to<T>,
                          Allocator>;

template <typename T,
         typename Hash,
         typename Allocator>
concurrent_unordered_set( std::initializer_list<T>,
                        set_size_type,
                        Hash,
                        Allocator )
-> concurrent_unordered_set<T,
                          Hash,
                          std::equal_to<T>,
                          Allocator>;

```

Where the `set_size_type` type refers to the `size_type` member type of the deduced `concurrent_unordered_set` and the type alias `iterator_value_t` is defined as follows:

```
template <typename InputIterator>
using iterator_value_t = typename std::iterator_traits<InputIterator>::value_type;
```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `Hash` type does not meet the `Allocator` requirements.
- The `KeyEqual` type does not meet the `Allocator` requirements.

Example

```
#include <oneapi/tbb/concurrent_unordered_set.h>
#include <vector>
#include <functional>

struct CustomHasher {...};

int main() {
    std::vector<int> v;

    // Deduces s1 as concurrent_unordered_set<int>
    oneapi::tbb::concurrent_unordered_set s1(v.begin(), v.end());

    // Deduces s2 as concurrent_unordered_set<int, CustomHasher>;
    oneapi::tbb::concurrent_unordered_set s2(v.begin(), v.end(), CustomHasher{});
}
```

concurrent_unordered_multiset

[containers.concurrent_unordered_multiset]

`oneapi::tbb::concurrent_unordered_multiset` is a class template that represents an unordered sequence of elements. It supports concurrent insertion, lookup, and traversal, but does not support concurrent erasure. In this container, multiple equivalent elements can be stored.

Class Template Synopsis

```
// Defined in header <oneapi/tbb/concurrent_unordered_set.h>

namespace oneapi {
    namespace tbb {
        template <typename T,
                 typename Hash = std::hash<Key>,
                 typename KeyEqual = std::equal_to<Key>,
                 typename Allocator = tbb_allocator<std::pair<const Key, T>>>
        class concurrent_unordered_multiset {
        public:

```

Requirements:

- The expression `std::allocator_type<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of type `value_type`, must be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `Hash` must meet the `Hash` requirements from the [hash] ISO C++ Standard section.
- The type `KeyEqual` must meet the `BinaryPredicate` requirements from the [algorithms.general] ISO C++ Standard section.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Description

`oneapi::tbb::concurrent_unordered_multiset` is an unordered sequence, which elements are organized into buckets. The value of the hash function `Hash` for `Key` object determines the number of the bucket in which the corresponding element will be placed.

If the qualified-id `Hash::transparent_key_equal` is valid and denotes a type, the member type `concurrent_unordered_multiset::key_equal` is defined as the value of this qualified-id. In this case, the program is ill-formed if any of the following conditions are met:

- The template parameter `KeyEqual` is different from `std::equal_to<Key>`.
- Qualified-id `Hash::transparent_key_equal::is_transparent` is not valid or does not denote a type.

Otherwise, the member type `concurrent_unordered_multiset::key_equal` is defined as the value of the template parameter `KeyEqual`.

Member functions

Construction, destruction, copying

Empty container constructors

```
concurrent_unordered_multiset();

explicit concurrent_unordered_multiset( const allocator_type& alloc );
```

Constructs an empty `concurrent_unordered_multiset`. The initial number of buckets is unspecified. If provided, uses the allocator `alloc` to allocate the memory.

```
explicit concurrent_unordered_multiset( size_type bucket_count,
                                       const hasher& hash = hasher(),
                                       const key_equal& equal = key_equal(),
                                       const allocator_type& alloc =
↳allocator_type() );

concurrent_unordered_multiset( size_type bucket_count, const allocator_type&
↳alloc );

concurrent_unordered_multiset( size_type bucket_count, const hasher& hash,
                               const allocator_type& alloc );
```

Constructs an empty `concurrent_unordered_multiset` with `bucket_count` buckets.

If provided, uses the hash function `hasher`, predicate `equal` to compare `key_type` objects for equality, and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```

template <typename InputIterator>
concurrent_unordered_multiset( InputIterator first, InputIterator last,
                               size_type bucket_count = /*implementation-
↳defined*/,
                               const hasher& hash = hasher(),
                               const key_equal& equal = key_equal(),
                               const allocator_type& alloc = allocator_type()↳
↳);

template <typename InputIterator>
concurrent_unordered_multiset( InputIterator first, InputIterator last,
                               size_type bucket_count, const allocator_type&↳
↳alloc );

template <typename InputIterator>
concurrent_unordered_multiset( InputIterator first, InputIterator last,
                               size_type bucket_count, const hasher& hash,
                               const allocator_type& alloc );

```

Constructs the `concurrent_unordered_multiset`, which contains the elements from the half-open interval `[first, last)`.

If provided uses the hash function `hasher`, predicate `equal` to compare `key_type` objects for equality, and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of `InputIterator` from the `[input.iterators]` ISO C++ Standard section.

```

concurrent_unordered_multiset( std::initializer_list<value_type> init,
                               size_type bucket_count = /*implementation-
↳defined*/,
                               const hasher& hash = hasher(),
                               const key_equal& equal = key_equal(),
                               const allocator_type& alloc = allocator_type()↳
↳);

```

Equivalent to `concurrent_unordered_multiset(init.begin(), init.end(), bucket_count, hash, equal, alloc)`.

```

concurrent_unordered_multiset( std::initializer_list<value_type> init,
                               size_type bucket_count, const allocator_type&↳
↳alloc );

```

Equivalent to `concurrent_unordered_multiset(init.begin(), init.end(), bucket_count, alloc)`.

```

concurrent_unordered_multiset( std::initializer_list<value_type> init,
                               size_type bucket_count, const hasher& hash,
                               const allocator_type& alloc );

```

Equivalent to `concurrent_unordered_multiset(init.begin(), init.end(), bucket_count, hash, alloc)`.

Copying constructors

```
concurrent_unordered_multiset( const concurrent_unordered_multiset& other );
concurrent_unordered_multiset( const concurrent_unordered_multiset& other,
                               const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_unordered_multiset( concurrent_unordered_multiset&& other );
concurrent_unordered_multiset( concurrent_unordered_multiset&& other,
                               const allocator_type& alloc );
```

Constructs a `concurrent_unordered_multiset` with the contents of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_unordered_multiset();
```

Destroys the `concurrent_unordered_multiset`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_unordered_multiset& operator=( const concurrent_unordered_multiset&
↳ other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_unordered_multiset& operator=( concurrent_unordered_multiset&&
↳ other ) noexcept( /*See below*/ );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

Exceptions: `noexcept` specification:

```
noexcept( std::allocator_traits<allocator_type>::is_always_equal::value
↳ &&
          std::is_nothrow_move_assignable<hasher>::value &&
          std::is_nothrow_move_assignable<key_equal>::value )
```

```
concurrent_unordered_multiset& operator=( std::initializer_list<value_type>
↳ init );
```

Replaces all elements in `*this` by the elements in `init`.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

Iterators

The types `concurrent_unordered_multiset::iterator` and `concurrent_unordered_multiset::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

begin and cbegin

```
iterator begin();  
const_iterator begin() const;  
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();  
const_iterator end() const;  
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: true if the container is empty; false, otherwise.

The result may differ with the actual container state in case of pending concurrent insertions.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ with the actual container size in case of pending concurrent insertions.

max_size

```
size_type max_size() const;
```

Returns: the maximum number of elements that container can hold.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other, lookup methods and while traversing the container.

Inserting values

```
std::pair<iterator, bool> insert( const value_type& value )
```

Inserts the value `value` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

```
iterator insert( const_iterator hint, const value_type& other )
```

Inserts the value `value` into the container.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

Returns: an `iterator` to the inserted element.

```
std::pair<iterator, bool> insert( value_type&& value )
```

Inserts the value `value` into the container using move semantics.

`value` is left in a valid, but unspecified state.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

```
iterator insert( const_iterator hint, value_type&& other )
```

Inserts the value `value` into the container using move semantics.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

`value` is left in a valid, but unspecified state.

Returns: an `iterator` to the inserted element.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last )
```

Inserts all items from the half-open interval `[first, last)` into the container.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from the [input. iterators] ISO C++ Standard section.

```
void insert( std::initializer_list<value_type> init )
```

Equivalent to `insert(init.begin(), init.end())`.

Inserting nodes

```
std::pair<iterator, bool> insert( node_type&& nh )
```

If the node handle `nh` is empty, does nothing.

Otherwise - inserts the node, owned by `nh` into the container.

`nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: `std::pair<iterator, bool>` where `iterator` points to the inserted element. Boolean value is always `true`.

```
iterator insert( const_iterator hint, node_type&& nh )
```

If the node handle `nh` is empty, does nothing.

Otherwise - inserts the node, owned by `nh` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

`nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: an iterator pointing to the inserted element.

Emplacing elements

```
template <typename... Args>
std::pair<iterator, bool> emplace( Args&&... args )
```

Inserts an element ,constructed in-place from `args` into the container.

Returns: `std::pair<iterator, bool>` where `iterator` points to the inserted element. Boolean value is always `true`.

```
template <typename... Args>
iterator emplace_hint( const_iterator hint, Args&&... args )
```

Inserts an element ,constructed in-place from `args` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

Returns: an iterator to the inserted element.

Merging containers

```

template <typename SrcHash, SrcKeyEqual>
void merge( concurrent_unordered_set<T, SrcHash, SrcKeyEqual, Allocator>&&
↳source )

template <typename SrcHash, SrcKeyEqual>
void merge( concurrent_unordered_set<T, SrcHash, SrcKeyEqual, Allocator>&&
↳source )

template <typename SrcHash, SrcKeyEqual>
void merge( concurrent_unordered_multiset<T, SrcHash, SrcKeyEqual, Allocator>&&
↳source )

template <typename SrcHash, SrcKeyEqual>
void merge( concurrent_unordered_multiset<T, SrcHash, SrcKeyEqual, Allocator>&&
↳ source )

```

Transfers all elements from source to *this.

No copy or move constructors of value_type are performed.

The behavior is undefined if get_allocator() != source.get_allocator().

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Clearing

```
void clear();
```

Removes all elements from the container.

Erasing elements

```

iterator unsafe_erase( const_iterator pos );

iterator unsafe_erase( iterator pos );

```

Removes the element pointed to by pos from the container.

Invalidates all iterators and references to the removed element.

Returns: iterator that follows the removed element.

Requirements: the iterator pos should be valid, dereferenceable and point to the element in *this.

```
size_type unsafe_erase( const key_type& key );
```

Removes the element equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

Returns: the number of removed elements.

```
template <typename K>
size_type unsafe_erase( const K& key );
```

Removes the element that is equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

This overload only participates in overload resolution if all of the following conditions are met:

- The qualified-id `hasher::transparent_key_equal` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the number of removed elements.

Erasing sequences

```
iterator unsafe_erase( const_iterator first, const_iterator last );
```

Removes all elements from the half-open interval `[first, last)` from the container.

Returns: iterator that follows the last removed element.

Requirements: the range `[first, last)` must be a valid subrange in `*this`.

Extracting nodes

```
node_type unsafe_extract( iterator pos );
node_type unsafe_extract( const_iterator pos );
```

Transfers ownership of the element pointed to by `pos` from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
node_type unsafe_extract( const key_type& key );
```

If an element equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

If there are multiple elements equivalent to `key`, it is unspecified which element should be transferred.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element or an empty node handle if an element equivalent to `key` was not found.

```
template <typename K>
node_type unsafe_extract( const K& key );
```

If an element equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

If there are multiple elements which are equivalent to `key`, it is unspecified which element should be transferred.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

This overload only participates in overload resolution if all of the following conditions are met:

- The qualified-id `hasher::transparent_key_equal` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the node handle that owns the extracted element or an empty node handle if an element equivalent to `key` was not found.

swap

```
void swap( concurrent_unordered_multiset& other ) noexcept( /*See below*/ );
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Exceptions: `noexcept` specification:

```
noexcept( std::allocator_traits<allocator_type>::is_always_equal::value_
->&&
         std::is_nothrow_swappable<hasher>::value &&
         std::is_nothrow_swappable<key_equal>::value )
```

Lookup

All methods in this section can be executed concurrently with each other, concurrently-safe modifiers and while traversing the container.

count

```
size_type count( const key_type& key );
```

Returns: the number of elements equivalent to key.

```
template <typename K>
size_type count( const K& key );
```

Returns: the number of elements that are equivalent to key.

This overload only participates in overload resolution if qualified-id `hasher::transparent_key_equal` is valid and denotes a type.

find

```
iterator find( const key_type& key );
const_iterator find( const key_type& key ) const;
```

Returns: an iterator to the element equivalent to key, or `end()` if no such element exists.

If there are multiple elements equivalent to key, it is unspecified which element should be found.

```
template <typename K>
iterator find( const K& key );

template <typename K>
const_iterator find( const K& key ) const;
```

Returns: an iterator to the element equivalent to key, or `end()` if no such element exists.

If there are multiple elements equivalent to key, it is unspecified which element should be found.

These overloads only participate in overload resolution if qualified-id `hasher::transparent_key_equal` is valid and denotes a type.

contains

```
bool contains( const key_type& key ) const;
```

Returns: true if at least one element equivalent to `key` exists in the container; false, otherwise.

```
template <typename K>
bool contains( const K& key ) const;
```

Returns: true if at least one element equal to `key` exists in the container; false, otherwise.

This overload only participates in overload resolution if qualified-id `hasher::transparent_key_equal` is valid and denotes a type.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );
std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↳const;
```

Returns: if at least one element with the key equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to the first element equivalent to `key`, `l` is an iterator to the element that follows the last element equivalent to `key`. Otherwise, `{end(), end()}`.

```
template <typename K>
std::pair<iterator, iterator> equal_range( const K& key )

template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key )
```

Returns: if at least one element with the key equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to the first element equivalent to `key`, `l` is an iterator to the element that follows the last element equivalent to `key`. Otherwise, `{end(), end()}`.

These overloads participate in overload resolution only if qualified-id `hasher::transparent_key_equal` is valid and denotes a type.

Bucket interface

The types `concurrent_unordered_multiset::local_iterator` and `concurrent_unordered_multiset::const_local_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ Standard section.

These iterators are used to traverse the certain bucket.

All methods in this section can only be executed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Bucket begin and bucket end

```
local_iterator unsafe_begin( size_type n );  
const_local_iterator unsafe_begin( size_type n ) const;  
const_local_iterator unsafe_cbegin( size_type n ) const;
```

Returns: an iterator to the first element in the bucket number n.

```
local_iterator unsafe_end( size_type n );  
const_local_iterator unsafe_end( size_type n ) const;  
const_local_iterator unsafe_cend( size_type n ) const;
```

Returns: an iterator to the element that follows the last element in the bucket number n.

The number of buckets

```
size_type unsafe_bucket_count() const;
```

Returns: the number of buckets in the container.

```
size_type unsafe_max_bucket_count() const;
```

Returns: the maximum number of buckets that container can hold.

Size of the bucket

```
size_type unsafe_bucket_size( size_type n ) const;
```

Returns: the number of elements in the bucket number n.

Bucket number

```
size_type unsafe_bucket( const key_type& key ) const;
```

Returns: the number of the bucket in which the element with the key key is stored.

Hash policy

Hash policy of `concurrent_unordered_multiset` manages the number of buckets in the container and the allowed maximum number of elements per bucket (load factor). If the maximum load factor is exceeded, the container can automatically increase the number of buckets.

Load factor

```
float load_factor() const;
```

Returns: the average number of elements per bucket, which is `size()/unsafe_bucket_count()`.

```
float max_load_factor() const;
```

Returns: the maximum number of elements per bucket.

```
void max_load_factor( float ml );
```

Sets the maximum number of elements per bucket to `ml`.

Manual rehashing

```
void rehash( size_type n );
```

Sets the number of buckets to `n` and rehashes the container.

```
void reserve( size_type n );
```

Sets the number of buckets to the value that is needed to store `n` elements.

Observers

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with `*this`.

hash_function

```
hasher hash_function() const;
```

Returns: a copy of the hash function associated with *this.

key_eq

```
key_equal key_eq() const;
```

Returns: a copy of the key equality predicate associated with *this.

Parallel iteration

Member types `concurrent_unordered_multiset::range_type` and `concurrent_unordered_multiset::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_unordered_multiset::const_range_type` are of type `concurrent_unordered_multiset::const_iterator`, whereas the bounds for a `concurrent_unordered_multiset::range_type` are of type `concurrent_unordered_multiset::iterator`.

range member function

```
range_type range();
const_range_type range() const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provide binary comparison and swap operations on `oneapi::tbb::concurrent_unordered_multiset` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_unordered_multiset` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```
template <typename T, typename Hash,
          typename KeyEqual, typename Allocator>
void swap( concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& lhs,
           concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& rhs );

template <typename T, typename Hash,
          typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& rhs )
↔;
```

(continues on next page)

(continued from previous page)

```

template <typename T, typename Hash,
         typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& rhs )
↔);

```

Non-member swap

```

template <typename T, typename Hash,
         typename KeyEqual, typename Allocator>
void swap( concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& lhs,
           concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& rhs )
↔noexcept(noexcept(lhs.swap(rhs)));

```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two objects of `concurrent_unordered_multiset` are equal if the following conditions are true:

- They contain an equal number of elements.
- Each group of elements with the same key in one container has the corresponding group of equivalent elements in the other container (not necessarily in the same order).

```

template <typename T, typename Hash,
         typename KeyEqual, typename Allocator>
bool operator==( const concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& rhs )
↔);

```

Returns: true if lhs is equal to rhs; false, otherwise.

```

template <typename T, typename Hash,
         typename KeyEqual, typename Allocator>
bool operator!=( const concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& lhs,
                 const concurrent_unordered_multiset<T, Hash, KeyEqual, Allocator>& rhs )
↔);

```

Equivalent to `!(lhs == rhs)`.

Returns: true if lhs is not equal to rhs, false otherwise.

Other

Deduction guides

If possible, `concurrent_unordered_multiset` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```

template <typename InputIterator,
           typename Hash = std::hash<iterator_value_t<InputIterator>>,
           typename KeyEqual = std::equal_to<iterator_value_t<InputIterator>>,
           typename Allocator = tbb::tbb_allocator<iterator_value_t<InputIterator>>>
concurrent_unordered_multiset( InputIterator, InputIterator,
                              set_size_type = {},
                              Hash = Hash(),
                              KeyEqual = KeyEqual(),
                              Allocator = Allocator() )
-> concurrent_unordered_multiset<iterator_value_t<InputIterator>,
                               Hash,
                               KeyEqual,
                               Allocator>;

template <typename InputIterator,
           typename Allocator>
concurrent_unordered_multiset( InputIterator, InputIterator,
                              set_size_type,
                              Allocator )
-> concurrent_unordered_multiset<iterator_value_t<InputIterator>,
                               std::hash<iterator_value_t<InputIterator>>,
                               std::equal_to<iterator_value_t<InputIterator>>,
                               Allocator>;

template <typename T,
           typename Hash = std::hash<T>,
           typename KeyEqual = std::equal_to<T>,
           typename Allocator = tbb::tbb_allocator<T>>
concurrent_unordered_multiset( std::initializer_list<T>,
                              set_size_type = {},
                              Hash = Hash(),
                              KeyEqual = KeyEqual(),
                              Allocator = Allocator() )
-> concurrent_unordered_multiset<T,
                               Hash,
                               KeyEqual,
                               Allocator>;

template <typename T,
           typename Allocator>
concurrent_unordered_multiset( std::initializer_list<T>,
                              set_size_type,
                              Allocator )
-> concurrent_unordered_multiset<T,
                               std::hash<T>,

```

(continues on next page)

(continued from previous page)

```

        std::equal_to<T>,
        Allocator>;

template <typename T,
         typename Allocator>
concurrent_unordered_multiset( std::initializer_list<T>,
                             Allocator )
-> concurrent_unordered_multiset<T,
                               std::hash<T>,
                               std::equal_to<T>,
                               Allocator>;

template <typename T,
         typename Hash,
         typename Allocator>
concurrent_unordered_multiset( std::initializer_list<T>,
                              set_size_type,
                              Hash,
                              Allocator )
-> concurrent_unordered_multiset<T,
                              Hash,
                              std::equal_to<T>,
                              Allocator>;

```

Where the `set_size_type` type refers to the `size_type` member type of the deduced `concurrent_unordered_multiset` and the type alias `iterator_value_t` is defined as follows:

```

template <typename InputIterator>
using iterator_value_t = typename std::iterator_traits<InputIterator>::value_type;

```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `Hash` type does not meet the `Allocator` requirements.
- The `KeyEqual` type does not meet the `Allocator` requirements.

Example

```

#include <oneapi/tbb/concurrent_unordered_set.h>
#include <vector>
#include <functional>

struct CustomHasher {...};

int main() {
    std::vector<int> v;

    // Deduces s1 as concurrent_unordered_multiset<int>
    oneapi::tbb::concurrent_unordered_multiset s1(v.begin(), v.end());
}

```

(continues on next page)

(continued from previous page)

```

// Deduces s2 as concurrent_unordered_multiset<int, CustomHasher>;
oneapi::tbb::concurrent_unordered_multiset s2(v.begin(), v.end(), CustomHasher{});
}

```

Ordered associative containers

concurrent_map

[containers.concurrent_map]

oneapi::tbb::concurrent_map is a class template that represents a sorted associative container. It stores unique elements and supports concurrent insertion, lookup, and traversal, but does not support concurrent erasure.

Class Template Synopsis

```

namespace oneapi {
    namespace tbb {

        template <typename Key,
                 typename T,
                 typename Compare = std::less<Key>,
                 typename Allocator = tbb_allocator<std::pair<const Key, T>>
        class concurrent_map {
        public:
            using key_type = Key;
            using mapped_type = T;
            using value_type = std::pair<const Key, T>;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using key_compare = Compare;
            using allocator_type = Allocator;

            using reference = value_type&;
            using const_reference = const value_type&;
            using pointer = std::allocator_traits<Allocator>::pointer;
            using const_pointer = std::allocator_traits<Allocator>::const_pointer;

            using iterator = <implementation-defined ForwardIterator>;
            using const_iterator = <implementation-defined constant ForwardIterator>;

            using node_type = <implementation-defined node handle>;

            using range_type = <implementation-defined range>;
            using const_range_type = <implementation-defined constant node handle>;

            class value_compare;

```

// Parallel iteration
range_type range();
const_range_type range() const;
}; // class concurrent_map

} // namespace tbb
} // namespace oneapi

```

Requirements:

- The expression `std::allocator_traits<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of the type `value_type`, must be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `Compare` must meet the `Compare` requirements from the [alg.sorting] ISO C++ Standard section.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Member classes**value_compare**

`concurrent_map::value_compare` is a function object that is used to compare `concurrent_map::value_type` objects by comparing their first components.

Class Synopsis

```

namespace oneapi {
    namespace tbb {

        template <typename Key, typename T,
                 typename Compare, typename Allocator>
        class concurrent_map<Key, T, Compare, Allocator>::value_compare {
        protected:
            key_compare comp;

            value_compare( key_compare c );

        public:
            bool operator()( const value_type& lhs, const value_type& rhs )
            ↪const;
            }; // class value_compare

        } // namespace tbb
    } // namespace oneapi

```

Member objects

```
key_compare comp;
```

The key comparison function object.

Member functions

```
value_compare( key_compare c );
```

Constructs a `value_compare` with the stored key comparison function object `c`.

```
bool operator()( const value_type& lhs, const value_type& rhs ) const;
```

Compares `lhs.first` and `rhs.first` by calling the stored key comparison function `comp`.

Returns: true if first components of `lhs` and `rhs` are equal; false, otherwise.

Member functions

Construction, destruction, copying

Empty container constructors

```

concurrent_map();

explicit concurrent_map( const key_compare& comp,
                        const allocator_type& alloc = allocator_type() );

explicit concurrent_map( const allocator_type& alloc );

```

Constructs an empty `concurrent_map`.

If provided, uses the comparison function object `comp` for all `key_type` comparisons and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```

template <typename InputIterator>
concurrent_map( InputIterator first, InputIterator last,
               const key_compare& comp = key_compare(),
               const allocator_type& alloc = allocator_type() );

template <typename InputIterator>
concurrent_map( InputIterator first, InputIterator last,
               const allocator_type& alloc = allocator_type() );

```

Constructs the `concurrent_map`, which contains the elements from the half-open interval `[first, last)`.

If the range `[first, last)` contains multiple elements with equal keys, it is unspecified which element would be inserted.

If provided, uses the comparison function object `comp` for all `key_type` comparisons and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from the `[input.iterators]` ISO C++ Standard section.

```

concurrent_map( std::initializer_list<value_type> init, const key_compare& comp,
               const allocator_type& alloc = allocator_type() );

```

Equivalent to `concurrent_map(init.begin(), init.end(), comp, alloc)`.

```

concurrent_map( std::initializer_list<value_type> init,
               const allocator_type& alloc );

```

Equivalent to `concurrent_map(init.begin(), init.end(), alloc)`.

Copying constructors

```
concurrent_map( const concurrent_map& other );
concurrent_map( const concurrent_map& other, const allocator_type& alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_map( concurrent_map&& other );
concurrent_map( concurrent_map&& other, const allocator_type& alloc );
```

Constructs a *concurrent_map* with the contents of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_map();
```

Destroys the `concurrent_map`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_map& operator=( const concurrent_map& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_map& operator=( concurrent_map&& other );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment` is true.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_map& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

If `init` contains multiple elements with equal keys, it is unspecified which element would be inserted.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

Element access

at

```
value_type& at( const key_type& key );
const value_type& at( const key_type& key ) const;
```

Returns: a reference to `item.second`, where `item` is the element with the key equivalent to `key`.

Throws: `std::out_of_range` exception if the element with the key equivalent to `key` is not present in the container.

operator[]

```
value_type& operator[]( const key_type& key );
```

If the element with the key equivalent to `key` is not present in the container, inserts a new element constructed in-place from `std::piecewise_construct`, `std::forward_as_tuple(key)`, `std::tuple<>()`.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

Returns: a reference to `item.second`, where `item` is the element with the key equivalent to `key`.

```
value_type& operator[]( key_type&& key );
```

If the element with the key equivalent to `key` is not present in the container, inserts a new element, constructed in-place from `std::piecewise_construct`, `std::forward_as_tuple(std::move(key))`, `std::tuple<>()`.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

Returns: a reference to `item.second`, where `item` is the element with the key equivalent to `key`.

Iterators

The types `concurrent_map::iterator` and `concurrent_map::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ standard section.

begin and cbegin

```
iterator begin();  
const_iterator begin() const;  
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();  
const_iterator end() const;  
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: `true` if the container is empty; `false`, otherwise.

The result may differ with the actual container state in case of pending concurrent insertions.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ with the actual container size in case of pending concurrent insertions.

max_size

```
size_type max_size() const;
```

Returns: the maximum number of elements that container can hold.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other, lookup methods and while traversing the container.

Inserting values

```
std::pair<iterator, bool> insert( const value_type& value );
```

Attempts to insert the value `value` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, const value_type& other );
```

Attempts to insert the value `value` into the container.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

Returns: an `iterator` to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
template <typename P>
std::pair<iterator, bool> insert( P&& value );
```

Equivalent to `emplace(std::forward<P>(value))`.

This overload only participates in overload resolution if `std::is_constructible<value_type, P&&>::value` is `true`.

```
template <typename P>
iterator insert( const_iterator hint, P&& value );
```

Equivalent to `emplace_hint(hint, std::forward<P>(value))`.

This overload only participates in overload resolution if `std::is_constructible<value_type, P&&>::value` is true.

```
std::pair<iterator, bool> insert( value_type&& value );
```

Attempts to insert the value `value` into the container using move semantics.

`value` is left in a valid, but unspecified state.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, value_type&& other );
```

Attempts to insert the value `value` into the container using move semantics.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

`value` is left in a valid, but unspecified state.

Returns: an `iterator` to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last );
```

Attempts to insert all items from the half-open interval `[first, last)` into the container.

If the interval `[first, last)` contains multiple elements with equal keys, it is unspecified which element should be inserted.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from the [input.iterators] ISO C++ Standard section.

```
void insert( std::initializer_list<value_type> init );
```

Equivalent to `insert(init.begin(), init.end())`.

Inserting nodes

```
std::pair<iterator, bool> insert( node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, attempts to insert the node owned by `nh` into the container.

If the insertion fails, node handle `nh` keeps ownership of the node.

Otherwise, `nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with key equivalent to `nh.key()`. Boolean value is `true` if insertion took place; `false`, otherwise.

```
iterator insert( const_iterator hint, node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, attempts to insert the node owned by `nh` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

If the insertion fails, node handle `nh` keeps ownership of the node.

Otherwise - `nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: an iterator pointing to the inserted element or to an existing element with key equivalent to `nh.key()`.

Emplacing elements

```
template <typename... Args>
std::pair<iterator, bool> emplace( Args&&... args );
```

Attempts to insert an element ,constructed in-place from `args` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

```
template <typename... Args>
iterator emplace_hint( const_iterator hint, Args&&... args );
```

Attempts to insert an element constructed in-place from `args` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

Returns: an iterator to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

Merging containers

```
template <typename SrcCompare>
void merge( concurrent_map<Key, T, SrcCompare, Allocator>& source );

template <typename SrcCompare>
void merge( concurrent_map<Key, T, SrcCompare, Allocator>&& source );

template <typename SrcCompare>
void merge( concurrent_multimap<Key, T, SrcCompare, Allocator>& source );

template <typename SrcCompare>
void merge( concurrent_multimap<Key, T, SrcCompare, Allocator>&& source );
```

Transfers those elements from `source` which keys do not exist in the container.

In case of merging with the container with multiple elements with equal keys, it is unspecified which element would be transferred.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `get_allocator() != source.get_allocator()`.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Clearing

```
void clear();
```

Removes all elements from the container.

Erasing elements

```
iterator unsafe_erase( const_iterator pos );

iterator unsafe_erase( iterator pos );
```

Removes the element pointed to by `pos` from the container.

Invalidates all iterators and references to the removed element.

Returns: iterator which follows the removed element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
size_type unsafe_erase( const key_type& key );
```

Removes the element with the key equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

Returns: 1 if an element with the key equivalent to `key` exists; 0, otherwise.

```
template <typename K>
size_type unsafe_erase( const K& key );
```

Removes the element with the key that is equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

This overload only participates in overload resolution if all of the following statements are true:

- The qualified-id `key_compare::is_transparent` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: 1 if an element with the key equivalent to `key` exists; 0, otherwise.

Erasing sequences

```
iterator unsafe_erase( const_iterator first, const_iterator last );
```

Removes all elements from the half-open interval `[first, last)` from the container.

Returns: iterator that follows the last removed element.

Requirements: the range `[first, last)` must be a valid subrange in `*this`.

Extracting nodes

```
node_type unsafe_extract( iterator pos );
node_type unsafe_extract( const_iterator pos );
```

Transfers ownership of the element pointed to by `pos` from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
node_type unsafe_extract( const key_type& key );
```

If an element with the key equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element or an empty node handle if an element with the key equivalent to `key` was not found.

```
template <typename K>
node_type unsafe_extract( const K& key );
```

If an element with the key equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

This overload only participates in overload resolution if all of the following statements are `true`:

- The qualified-id `key_compare::is_transparent` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is `false`.
- `std::is_convertible<K, const_iterator>::value` is `false`.

Returns: the node handle that owns the extracted element or an empty node handle if an element with the key equivalent to `key` was not found.

swap

```
void swap( concurrent_map& other );
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is `true`.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Lookup

All methods in this section can be executed concurrently with each other, concurrently-safe modifiers, and while traversing the container.

count

```
size_type count( const key_type& key );
```

Returns: the number of elements with the key equivalent to key.

```
template <typename K>
size_type count( const K& key );
```

Returns: the number of elements with the key that is equivalent to key.

This overload only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

find

```
iterator find( const key_type& key );
const_iterator find( const key_type& key ) const;
```

Returns: an iterator to the element with the key equivalent to key, or `end()` if no such element exists.

```
template <typename K>
iterator find( const K& key );

template <typename K>
const_iterator find( const K& key ) const;
```

Returns: an iterator to the element with the key equivalent to key, or `end()` if no such element exists.

These overloads only participate in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

contains

```
bool contains( const key_type& key ) const;
```

Returns: true if an element with the key equivalent to key exists in the container; false, otherwise.

```
template <typename K>
bool contains( const K& key ) const;
```

Returns: true if an element with the key that is equivalent to key exists in the container; false, otherwise.

This overload only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

lower_bound

```
iterator lower_bound( const key_type& key );
const_iterator lower_bound( const key_type& key ) const;
```

Returns: an iterator to the first element in the container with the key that is *not less* than key.

```
template <typename K>
iterator lower_bound( const K& key )

template <typename K>
const_iterator lower_bound( const K& key ) const
```

Returns: an iterator to the first element in the container with the key that is *not less* than key.

These overloads only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

upper_bound

```
iterator upper_bound( const key_type& key );
const_iterator upper_bound( const key_type& key ) const;
```

Returns: an iterator to the first element in the container with the key that compares *greater* than key.

```
template <typename K>
iterator upper_bound( const K& key );

template <typename K>
const_iterator upper_bound( const K& key ) const;
```

Returns: an iterator to the first element in the container with the key that compares *greater* than key.

These overloads only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );
std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↪ const;
```

Returns: if an element with the key equivalent to key exists, a pair of iterators {f, l}, where f is an iterator to this element, l is `std::next(f)`. Otherwise, {end(), end()}.

```
template <typename K>
std::pair<iterator, iterator> equal_range( const K& key )
```

```
template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key )
```

Returns: if an element with the key that is equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to this element, `l` is `std::next(f)`. Otherwise, `{end(), end()}`.

These overloads only participate in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

Observers

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with `*this`.

key_comp

```
key_compare key_comp() const;
```

Returns: a copy of the key comparison functor associated with `*this`.

value_comp

```
value_compare value_comp() const;
```

Returns: an object of the `value_compare` class that is used to compare `value_type` objects.

Parallel iteration

Member types `concurrent_map::range_type` and `concurrent_map::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_map::const_range_type` are of type `concurrent_map::const_iterator`, whereas the bounds for a `concurrent_map::range_type` are of type `concurrent_map::iterator`.

range member function

```
range_type range();

const_range_type range() const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provide binary and lexicographical comparison and swap operations on `oneapi::tbb::concurrent_map` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_map` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```
template <typename Key, typename T, typename Compare, typename Allocator>
void swap( concurrent_map<Key, T, Compare, Allocator>& lhs,
           concurrent_map<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                 const concurrent_map<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                 const concurrent_map<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator<( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                const concurrent_map<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                const concurrent_map<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator<=( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                 const concurrent_map<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>=( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                 const concurrent_map<Key, T, Compare, Allocator>& rhs );
```

Non-member swap

```
template <typename Key, typename T, typename Compare, typename Allocator>
void swap( concurrent_map<Key, T, Compare, Allocator>& lhs,
           concurrent_map<Key, T, Compare, Allocator>& rhs );
```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two `oneapi::tbb::concurrent_map` objects are equal if they have the same number of elements and each element in one container is equal to the element in other container on the same position.

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                 const concurrent_map<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is equal to rhs; false, otherwise.

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                 const concurrent_map<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is not equal to rhs; false, otherwise.

Non-member lexicographical comparisons

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator<( const concurrent_map<Key, T, Compare, Allocator>& lhs,
               const concurrent_map<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *less* than rhs.

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator<=( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                const concurrent_map<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *less or equal* than rhs.

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_map<Key, T, Compare, Allocator>& lhs,
               const concurrent_map<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *greater* than rhs.

```

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>=( const concurrent_map<Key, T, Compare, Allocator>& lhs,
                const concurrent_map<Key, T, Compare, Allocator>& rhs )

```

Returns: true if lhs is lexicographically *greater or equal* than rhs.

Other

Deduction guides

If possible, `concurrent_map` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```

template <typename InputIterator,
         typename Compare = std::less<iterator_key_t<InputIterator>>,
         typename Allocator = tbb_allocator<iterator_alloc_value_t<InputIterator>>>
concurrent_map( InputIterator, InputIterator,
               Compare = Compare(),
               Allocator = Allocator() )
-> concurrent_map<iterator_key_t<InputIterator>,
                iterator_mapped_t<InputIterator>,
                Compare,
                Allocator>;

```

```

template <typename InputIterator,
         typename Allocator>
concurrent_map( InputIterator, InputIterator,
               Allocator )
-> concurrent_map<iterator_key_t<InputIterator>,
                iterator_mapped_t<InputIterator>,
                std::less<iterator_key_t<InputIterator>>,
                Allocator>;

```

```

template <typename Key, typename T,
         typename Compare = std::less<std::remove_const_t<Key>>,
         typename Allocator = tbb_allocator<std::pair<const Key, T>>>
concurrent_map( std::initializer_list<std::pair<Key, T>>,
               Compare = Compare(),
               Allocator = Allocator() )
-> concurrent_map<std::remove_const_t<Key>,
                T,
                Compare,
                Allocator>;

```

```

template <typename Key, typename T,
         typename Allocator>
concurrent_map( std::initializer_list<std::pair<Key, T>>, Allocator )
-> concurrent_map<std::remove_const_t<Key>,
                T,
                std::less<std::remove_const_t<Key>>,
                Allocator>;

```

where the type aliases `iterator_key_t`, `iterator_mapped_t`, `iterator_alloc_value_t` are defined as follows:

```
template <typename InputIterator>
using iterator_key_t = std::remove_const_t<typename std::iterator_traits<InputIterator>
↳::value_type::first_type>;

template <typename InputIterator>
using iterator_mapped_t = typename std::iterator_traits<InputIterator>::value_
↳type::second_type;

template <typename InputIterator>
using iterator_alloc_value_t = std::pair<std::add_const_t<iterator_key_t<InputIterator>>,
iterator_mapped_t<InputIterator>>;
```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `Compare` type does not meet the `Allocator` requirements.

Example

```
#include <oneapi/tbb/concurrent_map.h>
#include <vector>

int main() {
    std::vector<std::pair<int, float>> v;

    // Deduces cm1 as concurrent_map<int, float>
    oneapi::tbb::concurrent_map cm1(v.begin(), v.end());

    // Deduces cm2 as concurrent_map<int, float>
    oneapi::tbb::concurrent_map cm2({std::pair(1, 2f), std::pair(2, 3f)});
}
```

concurrent_multimap

[containers.concurrent_multimap]

`oneapi::tbb::concurrent_multimap` is a class template that represents a sorted associative container. It supports concurrent insertion, lookup, and traversal, but does not support concurrent erasure. In this container, multiple elements with equal keys can be stored.

Class Template Synopsis

```

namespace oneapi {
    namespace tbb {

        template <typename Key,
                 typename T,
                 typename Compare = std::less<Key>,
                 typename Allocator = tbb_allocator<std::pair<const Key, T>>
        class concurrent_multimap {
        public:
            using key_type = Key;
            using mapped_type = T;
            using value_type = std::pair<const Key, T>;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using key_compare = Compare;
            using allocator_type = Allocator;

            using reference = value_type&;
            using const_reference = const value_type&;
            using pointer = std::allocator_traits<Allocator>::pointer;
            using const_pointer = std::allocator_traits<Allocator>::const_pointer;

            using iterator = <implementation-defined ForwardIterator>;
            using const_iterator = <implementation-defined constant ForwardIterator>;

            using node_type = <implementation-defined node handle>;

            using range_type = <implementation-defined range>;
            using const_range_type = <implementation-defined constant node handle>;

            class value_compare;

            // Construction, destruction, copying
            concurrent_multimap();
            explicit concurrent_multimap( const key_compare& comp,
                                         const allocator_type& alloc = allocator_type() );
            ↪);

            explicit concurrent_multimap( const allocator_type& alloc );

            template <typename InputIterator>
            concurrent_multimap( InputIterator first, InputIterator last,
                                const key_compare& comp = key_compare(),
                                const allocator_type& alloc = allocator_type() );

            template <typename InputIterator>
            concurrent_multimap( InputIterator first, InputIterator last,
                                const allocator_type& alloc );

```

}; // class concurrent_multimap

} // namespace tbb
} // namespace oneapi

```

Requirements:

- The expression `std::allocator_traits<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of the type `value_type`, must be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `Compare` must meet the `Compare` requirements from the [alg.sorting] ISO C++ Standard section.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Member classes**value_compare**

`concurrent_multimap::value_compare` is a function object that is used to compare `concurrent_multimap::value_type` objects by comparing their first components.

Class Synopsis

```

namespace oneapi {
    namespace tbb {

        template <typename Key, typename T,
                 typename Compare, typename Allocator>
        class concurrent_multimap<Key, T, Compare, Allocator>::value_compare {
        protected:
            key_compare comp;

            value_compare( key_compare c );

        public:
            bool operator()( const value_type& lhs, const value_type& rhs ) const;
        }; // class value_compare

    } // namespace tbb
} // namespace oneapi

```

Member objects

```
key_compare comp;
```

The key comparison function object.

Member functions

```
value_compare( key_compare c );
```

Constructs a `value_compare` with the stored key comparison function object `c`.

```
bool operator()( const value_type& lhs, const value_type& rhs ) const;
```

Compares `lhs.first` and `rhs.first` by calling the stored key comparison function `comp`.

Returns: true if first components of `lhs` and `rhs` are equal; false, otherwise.

Member functions

Construction, destruction, copying

Empty container constructors

```
concurrent_multimap();

explicit concurrent_multimap( const key_compare& comp,
                             const allocator_type& alloc = allocator_type() );

explicit concurrent_multimap( const allocator_type& alloc );
```

Constructs an empty `concurrent_multimap`.

If provided, uses the comparison function object `comp` for all `key_type` comparisons and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```
template <typename InputIterator>
concurrent_multimap( InputIterator first, InputIterator last,
                   const key_compare& comp = key_compare(),
                   const allocator_type& alloc = allocator_type() );

template <typename InputIterator>
concurrent_multimap( InputIterator first, InputIterator last,
                   const allocator_type& alloc = allocator_type() );
```

Constructs the `concurrent_multimap`, which contains all elements from the half-open interval `[first, last)`.

If provided, uses the comparison function object `comp` for all `key_type` comparisons and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from `[input.iterators]` ISO C++ Standard section.

```
concurrent_multimap( std::initializer_list<value_type> init, const key_compare&
↪ comp = key_compare(),
                    const allocator_type& alloc = allocator_type() );
```

Equivalent to `concurrent_multimap(init.begin(), init.end(), comp, alloc)`.

```
concurrent_multimap( std::initializer_list<value_type> init,
                    const allocator_type& alloc );
```

Equivalent to `concurrent_multimap(init.begin(), init.end(), alloc)`.

Copying constructors

```
concurrent_multimap( const concurrent_multimap& other );

concurrent_multimap( const concurrent_multimap& other, const allocator_type&
↪ alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_multimap( concurrent_multimap&& other );

concurrent_multimap( concurrent_multimap&& other, const allocator_type& alloc
↪ );
```

Constructs a *concurrent_multimap* with the contents of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_multimap();
```

Destroys the `concurrent_multimap`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_multimap& operator=( const concurrent_multimap& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::is true`.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_multimap& operator=( concurrent_multimap&& other );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::is true`.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_multimap& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

If `init` contains multiple elements with equal keys, it is unspecified which element would be inserted.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

Iterators

The types `concurrent_multimap::iterator` and `concurrent_multimap::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ standard section.

begin and cbegin

```
iterator begin();  
const_iterator begin() const;  
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();  
const_iterator end() const;  
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: true if the container is empty, false otherwise.

The result may differ with the actual container state in case of pending concurrent insertions.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ with the actual container size in case of pending concurrent insertions.

max_size

```
size_type max_size() const;
```

Returns: the maximum number of elements that container can hold.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other, lookup methods and while traversing the container.

Emplacing elements

```
template <typename... Args>
std::pair<iterator, bool> emplace( Args&&... args );
```

Inserts an element constructed in-place from `args` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from [container.requirements] ISO C++ section.

```
template <typename... Args>
iterator emplace_hint( const_iterator hint, Args&&... args );
```

Inserts an element constructed in-place from `args` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

Returns: an iterator to the inserted element.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

Inserting values

```
std::pair<iterator, bool> insert( const value_type& value );
```

Inserts the value `value` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, const value_type& other );
```

Inserts the value `value` into the container.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

Returns: an iterator to the inserted element.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
template <typename P>
std::pair<iterator, bool> insert( P&& value );
```

Equivalent to `emplace(std::forward<P>(value))`.

This overload only participates in overload resolution if `std::is_constructible<value_type, P&&>::value` is true.

```
template <typename P>
iterator insert( const_iterator hint, P&& value );
```

Equivalent to `emplace_hint(hint, std::forward<P>(value))`.

This overload only participates in overload resolution if `std::is_constructible<value_type, P&&>::value` is true.

```
std::pair<iterator, bool> insert( value_type&& value );
```

Inserts the value `value` into the container using move semantics.

`value` is left in a valid, but unspecified state.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always true.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, value_type&& other );
```

Inserts the value `value` into the container using move semantics.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

`value` is left in a valid, but unspecified state.

Returns: an iterator to the inserted element.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last );
```

Inserts all items from the half-open interval `[first, last)` into the container.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from [input.iterators] the ISO C++ Standard section.

```
void insert( std::initializer_list<value_type> init );
```

Equivalent to `insert(init.begin(), init.end())`.

Inserting nodes

```
std::pair<iterator, bool> insert( node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, inserts the node owned by `nh` into the container.

`nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

```
iterator insert( const_iterator hint, node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, inserts the node owned by `nh` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

`nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: an iterator pointing to the inserted element.

Merging containers

```
template <typename SrcCompare>
void merge( concurrent_map<Key, T, SrcCompare, Allocator>& source );

template <typename SrcCompare>
void merge( concurrent_map<Key, T, SrcCompare, Allocator>&& source );

template <typename SrcCompare>
void merge( concurrent_multimap<Key, T, SrcCompare, Allocator>& source );

template <typename SrcCompare>
void merge( concurrent_multimap<Key, T, SrcCompare, Allocator>&& source );
```

Transfers all elements from `source` to `*this`.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `get_allocator() != source.get_allocator()`.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Clearing

```
void clear();
```

Removes all elements from the container.

Erasing elements

```
iterator unsafe_erase( const_iterator pos );  
iterator unsafe_erase( iterator pos );
```

Removes the element pointed to by `pos` from the container.

Invalidates all iterators and references to the removed element.

Returns: iterator which follows the removed element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
size_type unsafe_erase( const key_type& key );
```

Removes all element with the key equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed elements.

Returns: the number of removed elements.

```
template <typename K>  
size_type unsafe_erase( const K& key );
```

Removes all elements with the key that is equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed elements.

This overload only participates in overload resolution if all of the following statements are true:

- The qualified-id `key_compare::is_transparent` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the number of removed elements.

Erasing sequences

```
iterator unsafe_erase( const_iterator first, const_iterator last );
```

Removes all elements from the half-open interval `[first, last)` from the container.

Returns: iterator that follows the last removed element.

Requirements: the range `[first, last)` must be a valid subrange in `*this`.

Extracting nodes

```
node_type unsafe_extract( iterator pos );
node_type unsafe_extract( const_iterator pos );
```

Transfers ownership of the element pointed to by `pos` from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
node_type unsafe_extract( const key_type& key );
```

If at least one element with the key equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

If there are multiple elements with the key equivalent to `key`, it is unspecified which element should be transferred.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element or an empty node handle if an element with the key equivalent to `key` was not found.

```
template <typename K>
node_type unsafe_extract( const K& key );
```

If at least one element with the key that is equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

If there are multiple elements with the key that is equivalent to `key`, it is unspecified which element should be transferred.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

This overload only participates in overload resolution if all of the following statements are true:

- The qualified-id `key_compare::is_transparent` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the node handle that owns the extracted element or an empty node handle if an element with the key that is equivalent to `key` was not found.

swap

```
void swap( concurrent_multimap& other );
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Lookup

All methods in this section can be executed concurrently with each other, concurrently-safe modifiers and while traversing the container.

count

```
size_type count( const key_type& key );
```

Returns: the number of elements with the key equivalent to `key`.

```
template <typename K>
size_type count( const K& key );
```

Returns: the number of elements with the key equivalent to `key`.

This overload only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

find

```
iterator find( const key_type& key );
const_iterator find( const key_type& key ) const;
```

Returns: an iterator to the element with the key equivalent to `key`, or `end()` if no such element exists.

If there are multiple elements with the key equivalent to `key`, it is unspecified which element should be found.

```

template <typename K>
iterator find( const K& key );

template <typename K>
const_iterator find( const K& key ) const;

```

Returns: an iterator to the element with the key that is equivalent to `key`, or `end()` if no such element exists.

If there are multiple elements with the key that is equivalent to `key`, it is unspecified which element should be found.

These overloads only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

contains

```
bool contains( const key_type& key ) const;
```

Returns: true if an element with the key equivalent to `key` exists in the container; false, otherwise.

```

template <typename K>
bool contains( const K& key ) const;

```

Returns: true if an element with the key equivalent to `key` exists in the container; false, otherwise.

This overload only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

lower_bound

```

iterator lower_bound( const key_type& key );

const_iterator lower_bound( const key_type& key ) const;

```

Returns: an iterator to the first element in the container with the key that is *not less* than `key`.

```

template <typename K>
iterator lower_bound( const K& key )

template <typename K>
const_iterator lower_bound( const K& key ) const

```

Returns: an iterator to the first element in the container with the key that is *not less* than `key`.

These overloads only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

upper_bound

```
iterator upper_bound( const key_type& key );

const_iterator upper_bound( const key_type& key ) const;
```

Returns: an iterator to the first element in the container with the key that compares *greater* than key.

```
template <typename K>
iterator upper_bound( const K& key );

template <typename K>
const_iterator upper_bound( const K& key ) const;
```

Returns: an iterator to the first element in the container with the key that compares *greater* than key.

These overloads only participate in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );

std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↳const;
```

Returns: if at least one element with the key equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to the first element with the key equivalent to `key`, `l` is an iterator to the element that follows the last element with the key equivalent to `key`. Otherwise - `{end(), end()}`.

```
template <typename K>
std::pair<iterator, iterator> equal_range( const K& key )

template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key )
```

Returns: if at least one element with the key equivalent to `key` exists, a pair of iterators `{f, l}`, where `f` is an iterator to the first element with the key that is equivalent to `key`, `l` is an iterator to the element that follows the last element with the key that is equivalent to `key`. Otherwise, `{end(), end()}`.

These overloads only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

Observers

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with `*this`.

key_comp

```
key_compare key_comp() const;
```

Returns: a copy of the key comparison functor associated with `*this`.

value_comp

```
value_compare value_comp() const;
```

Returns: an object of the `value_compare` class that is used to compare `value_type` objects.

Parallel iteration

Member types `concurrent_multimap::range_type` and `concurrent_multimap::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_multimap::const_range_type` are of type `concurrent_multimap::const_iterator`, whereas the bounds for a `concurrent_multimap::range_type` are of type `concurrent_multimap::iterator`.

range member function

```
range_type range();
const_range_type range() const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provide binary and lexicographical comparison and swap operations on `oneapi::tbb::concurrent_multimap` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_multimap` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```

template <typename Key, typename T, typename Compare, typename Allocator>
void swap( concurrent_multimap<Key, T, Compare, Allocator>& lhs,
           concurrent_multimap<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
                 const concurrent_multimap<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
                 const concurrent_multimap<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator<( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
               const concurrent_multimap<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
               const concurrent_multimap<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator<=( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
                const concurrent_multimap<Key, T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>=( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
                const concurrent_multimap<Key, T, Compare, Allocator>& rhs );

```

Non-member swap

```

template <typename Key, typename T, typename Compare, typename Allocator>
void swap( concurrent_multimap<Key, T, Compare, Allocator>& lhs,
           concurrent_multimap<Key, T, Compare, Allocator>& rhs );

```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two `oneapi::tbb::concurrent_multimap` objects are equal if they have the same number of elements and each element in one container is equal to the element in other container on the same position.

```

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
                const concurrent_multimap<Key, T, Compare, Allocator>& rhs )

```

Returns: true if lhs is equal to rhs; false, otherwise.

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
                 const concurrent_multimap<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is not equal to rhs; false, otherwise.

Non-member lexicographical comparisons

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator<( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
               const concurrent_multimap<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *less* than rhs.

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator<=( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
                const concurrent_multimap<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *less or equal* than rhs.

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
               const concurrent_multimap<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *greater* than rhs.

```
template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>=( const concurrent_multimap<Key, T, Compare, Allocator>& lhs,
                const concurrent_multimap<Key, T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *greater or equal* than rhs.

Other

Deduction guides

If possible, `concurrent_multimap` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```
template <typename InputIterator,
         typename Compare = std::less<iterator_key_t<InputIterator>>,
         typename Allocator = tbb_allocator<iterator_alloc_value_t<InputIterator>>>
concurrent_multimap( InputIterator, InputIterator,
                    Compare = Compare(),
                    Allocator = Allocator() )
```

(continues on next page)

(continued from previous page)

```

-> concurrent_multimap<iterator_key_t<InputIterator>,
                      iterator_mapped_t<InputIterator>,
                      Compare,
                      Allocator>;

template <typename InputIterator,
          typename Allocator>
concurrent_multimap( InputIterator, InputIterator,
                    Allocator )
-> concurrent_multimap<iterator_key_t<InputIterator>,
                      iterator_mapped_t<InputIterator>,
                      std::less<iterator_key_t<InputIterator>>,
                      Allocator>;

template <typename Key, typename T,
          typename Compare = std::less<std::remove_const_t<Key>>,
          typename Allocator = tbb_allocator<std::pair<const Key, T>>>
concurrent_multimap( std::initializer_list<std::pair<Key, T>>,
                    Compare = Compare(),
                    Allocator = Allocator() )
-> concurrent_multimap<std::remove_const_t<Key>,
                      T,
                      Compare,
                      Allocator>;

template <typename Key, typename T,
          typename Allocator>
concurrent_multimap( std::initializer_list<std::pair<Key, T>>, Allocator )
-> concurrent_multimap<std::remove_const_t<Key>,
                      T,
                      std::less<std::remove_const_t<Key>>,
                      Allocator>;

```

where the type aliases `iterator_key_t`, `iterator_mapped_t`, `iterator_alloc_value_t` are defined as follows:

```

template <typename InputIterator>
using iterator_key_t = std::remove_const_t<typename std::iterator_traits<InputIterator>
↳::value_type::first_type>;

template <typename InputIterator>
using iterator_mapped_t = typename std::iterator_traits<InputIterator>::value_
↳type::second_type;

template <typename InputIterator>
using iterator_alloc_value_t = std::pair<std::add_const_t<iterator_key_t<InputIterator>>,
                                       iterator_mapped_t<InputIterator>>;

```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.

- The Compare type does not meet the Allocator requirements.

Example

```
#include <oneapi/tbb/concurrent_map.h>
#include <vector>

int main() {
    std::vector<std::pair<int, float>> v;

    // Deduces cm1 as concurrent_multimap<int, float>
    oneapi::tbb::concurrent_multimap cm1(v.begin(), v.end());

    // Deduces cm2 as concurrent_multimap<int, float>
    oneapi::tbb::concurrent_multimap cm2({std::pair(1, 2f), std::pair(2, 3f)});
}
```

concurrent_set

[containers.concurrent_set]

oneapi::tbb::concurrent_set is a class template that represents a sorted sequence of unique elements. It supports concurrent insertion, lookup and traversal, but does not support concurrent erasure.

Class Template Synopsis

```
// Defined in header <oneapi/tbb/concurrent_set.h>

namespace oneapi {
    namespace tbb {

        template <typename T,
                 typename Compare = std::less<T>,
                 typename Allocator = tbb_allocator<T>>
        class concurrent_set {
        public:
            using key_type = T;
            using value_type = T;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using key_compare = Compare;
            using value_compare = Compare;

            using allocator_type = Allocator;

            using reference = value_type&;
            using const_reference = const value_type&;
            using pointer = std::allocator_traits<Allocator>::pointer;
            using const_pointer = std::allocator_traits<Allocator>::const_pointer;
        };
    };
}
```

std::pair<iterator, iterator> equal_range( const K& key );
std::pair<const_iterator, const_iterator> equal_range( const K& key ) const;

iterator lower_bound( const key_type& key );
const_iterator lower_bound( const key_type& key ) const;

template <typename K>
iterator lower_bound( const K& key );

template <typename K>
const_iterator lower_bound( const K& key ) const;

```

(continues on next page)

(continued from previous page)

```

iterator upper_bound( const key_type& key );
const_iterator upper_bound( const key_type& key ) const;

template <typename K>
iterator upper_bound( const K& key );

template <typename K>
const_iterator upper_bound( const K& key ) const;

// Observers
key_compare key_comp() const;

value_compare value_comp() const;

// Parallel iteration
range_type range();
const_range_type range() const;
}; // class concurrent_set

} // namespace tbb
} // namespace oneapi

```

Requirements:

- The expression `std::allocator_traits<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of the type `value_type`, must be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `Compare` must meet the `Compare` requirements from the [alg.sorting] ISO C++ Standard section.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Member functions**Construction, destruction, copying****Empty container constructors**

```

concurrent_set();

explicit concurrent_set( const key_compare& comp,
                        const allocator_type& alloc = allocator_type() );

explicit concurrent_set( const allocator_type& alloc );

```

Constructs an empty `concurrent_set`.

If provided, uses the comparison function object `comp` for all `key_type` comparisons and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```

template <typename InputIterator>
concurrent_set( InputIterator first, InputIterator last,
                const key_compare& comp = key_compare(),
                const allocator_type& alloc = allocator_type() );

template <typename InputIterator>
concurrent_set( InputIterator first, InputIterator last,
                const allocator_type& alloc = allocator_type() );

```

Constructs the `concurrent_set` that contains the elements from the half-open interval `[first, last)`.

If the range `[first, last)` contains multiple equal elements, it is unspecified which element would be inserted.

If provided, uses the comparison function object `comp` for all `key_type` comparisons and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from the `[input.iterators]` ISO C++ Standard section.

```

concurrent_set( std::initializer_list<value_type> init, const key_compare& comp = key_compare(),
                const allocator_type& alloc = allocator_type() );

```

Equivalent to `concurrent_set(init.begin(), init.end(), comp, alloc)`.

```

concurrent_set( std::initializer_list<value_type> init,
                const allocator_type& alloc );

```

Equivalent to `concurrent_set(init.begin(), init.end(), alloc)`.

Copying constructors

```

concurrent_set( const concurrent_set& other );

concurrent_set( const concurrent_set& other, const allocator_type& alloc );

```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_set( concurrent_set&& other );
concurrent_set( concurrent_set&& other, const allocator_type& alloc );
```

Constructs a *concurrent_set* with the contents of *other* using move semantics.

other is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with *other*.

Destructor

```
~concurrent_set();
```

Destroys the *concurrent_set*. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with **this*.

Assignment operators

```
concurrent_set& operator=( const concurrent_set& other );
```

Replaces all elements in **this* by the copies of the elements in *other*.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::is true`.

The behavior is undefined in case of concurrent operations with **this* and *other*.

Returns: a reference to **this*.

```
concurrent_set& operator=( concurrent_set&& other );
```

Replaces all elements in **this* by the elements in *other* using move semantics.

other is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::is true`.

The behavior is undefined in case of concurrent operations with **this* and *other*.

Returns: a reference to **this*.

```
concurrent_set& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

If `init` contains multiple elements with equal keys, it is unspecified which element would be inserted.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

Iterators

The types `concurrent_set::iterator` and `concurrent_set::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ standard section.

begin and cbegin

```
iterator begin();  
const_iterator begin() const;  
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();  
const_iterator end() const;  
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: `true` if the container is empty; `false`, otherwise.

The result may differ from the actual container state in case of pending concurrent insertions.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ from the actual container size in case of pending concurrent insertions.

max_size

```
size_type max_size() const;
```

Returns: the maximum number of elements that container can hold.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other, lookup methods and while traversing the container.

Inserting values

```
std::pair<iterator, bool> insert( const value_type& value );
```

Attempts to insert the value `value` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, const value_type& other );
```

Attempts to insert the value `value` into the container.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

Returns: an `iterator` to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
std::pair<iterator, bool> insert( value_type&& value );
```

Attempts to insert the value `value` into the container using move semantics.

`value` is left in a valid, but unspecified state.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, value_type&& other );
```

Attempts to insert the value `value` into the container using move semantics.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

`value` is left in a valid, but unspecified state.

Returns: an iterator to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last );
```

Attempts to insert all items from the half-open interval `[first, last)` into the container.

If the interval `[first, last)` contains multiple equal elements, it is unspecified which element should be inserted.

Requirements: the type `InputIterator` must meet the requirements of `InputIterator` from the [input.iterators] ISO C++ Standard section.

```
void insert( std::initializer_list<value_type> init );
```

Equivalent to `insert(init.begin(), init.end())`.

Inserting nodes

```
std::pair<iterator, bool> insert( node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, attempts to insert the node owned by `nh` into the container.

If the insertion fails, node handle `nh` keeps ownership of the node.

Otherwise, `nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element equal to `nh.value()`. Boolean value is `true` if insertion took place; `false`, otherwise.

```
iterator insert( const_iterator hint, node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, attempts to insert the node owned by `nh` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

If the insertion fails, node handle `nh` remains ownership of the node.

Otherwise, `nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: an iterator pointing to the inserted element or to an existing element equal to `nh.value()`.

Emplacing elements

```
template <typename... Args>
std::pair<iterator, bool> emplace( Args&&... args );
```

Attempts to insert an element constructed in-place from `args` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element or to an existing element with equal key. Boolean value is `true` if insertion took place; `false`, otherwise.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

```
template <typename... Args>
iterator emplace_hint( const_iterator hint, Args&&... args );
```

Attempts to insert an element constructed in-place from `args` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

Returns: an iterator to the inserted element or to an existing element with equal key.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

Merging containers

```
template <typename SrcCompare>
void merge( concurrent_set<T, SrcCompare, Allocator>& source );

template <typename SrcCompare>
void merge( concurrent_set<T, SrcCompare, Allocator>&& source );

template <typename SrcCompare>
void merge( concurrent_multiset<T, SrcCompare, Allocator>& source );

template <typename SrcCompare>
void merge( concurrent_multiset<T, SrcCompare, Allocator>&& source );
```

Transfers those elements from `source` which keys do not exist in the container.

In case of merging with the container with multiple equal elements, it is unspecified which element would be transferred.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `get_allocator() != source.get_allocator()`.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Clearing

```
void clear();
```

Removes all elements from the container.

Erasing elements

```
iterator unsafe_erase( const_iterator pos );
```

```
iterator unsafe_erase( iterator pos );
```

Removes the element pointed to by `pos` from the container.

Invalidates all iterators and references to the removed element.

Returns: `iterator` that follows the removed element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
size_type unsafe_erase( const key_type& key );
```

Removes the element equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

Returns: 1 if an element equivalent to `key` exists; 0, otherwise.

```
template <typename K>
size_type unsafe_erase( const K& key );
```

Removes the element that is equivalent to `key` if it exists in the container.

Invalidates all iterators and references to the removed element.

This overload only participates in overload resolution if all of the following statements are `true`:

- The qualified-id `key_compare::is_transparent` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is `false`.

- `std::is_convertible<K, const_iterator>::value` is false.

Returns: 1 if an element equivalent to `key` exists; 0, otherwise.

Erasing sequences

```
iterator unsafe_erase( const_iterator first, const_iterator last );
```

Removes all elements from the half-open interval `[first, last)` from the container.

Returns: iterator that follows the last removed element.

Requirements: the range `[first, last)` must be a valid subrange in `*this`.

Extracting nodes

```
node_type unsafe_extract( iterator pos );
node_type unsafe_extract( const_iterator pos );
```

Transfers ownership of the element pointed to by `pos` from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
node_type unsafe_extract( const key_type& key );
```

If an element equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element or an empty node handle if an element equivalent to `key` was not found.

```
template <typename K>
node_type unsafe_extract( const K& key );
```

If an element equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

This overload only participates in overload resolution if all of the following statements are `true`:

- The qualified-id `key_compare::is_transparent` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the node handle that owns the extracted element or an empty node handle if an element equivalent to `key` was not found.

swap

```
void swap( concurrent_set& other );
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Lookup

All methods in this section can be executed concurrently with each other, concurrently-safe modifiers and while traversing the container.

count

```
size_type count( const key_type& key );
```

Returns: the number of elements equivalent to `key`.

```
template <typename K>
size_type count( const K& key );
```

Returns: the number of elements that are equivalent to `key`.

This overload only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

find

```
iterator find( const key_type& key );
const_iterator find( const key_type& key ) const;
```

Returns: an iterator to the element equivalent to `key`, or `end()` if no such element exists.

```

template <typename K>
iterator find( const K& key );

template <typename K>
const_iterator find( const K& key ) const;

```

Returns: an iterator to the element that is equivalent to `key`, or `end()` if no such element exists.

These overloads only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

contains

```
bool contains( const key_type& key ) const;
```

Returns: true if an element equivalent to `key` exists in the container; false, otherwise.

```

template <typename K>
bool contains( const K& key ) const;

```

Returns: true if an element equivalent to `key` exists in the container; false, otherwise.

This overload only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

lower_bound

```

iterator lower_bound( const key_type& key );

const_iterator lower_bound( const key_type& key ) const;

```

Returns: an iterator to the first element in the container that is *not less* than `key`.

```

template <typename K>
iterator lower_bound( const K& key )

template <typename K>
const_iterator lower_bound( const K& key ) const

```

Returns: an iterator to the first element in the container that is *not less* than `key`.

These overloads only participate in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

upper_bound

```
iterator upper_bound( const key_type& key );

const_iterator upper_bound( const key_type& key ) const;
```

Returns: an iterator to the first element in the container that compares *greater* than *key*.

```
template <typename K>
iterator upper_bound( const K& key );

template <typename K>
const_iterator upper_bound( const K& key ) const;
```

Returns: an iterator to the first element in the container that compares greater than *key*.

These overloads only participate in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );

std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↳const;
```

Returns: if an element equivalent to *key* exists, a pair of iterators {*f*, *l*}, where *f* is an iterator to this element, *l* is `std::next(f)`. Otherwise, {`end()`, `end()`}.

```
template <typename K>
std::pair<iterator, iterator> equal_range( const K& key )

template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key )
```

Returns: if an element equivalent to *key* exists, a pair of iterators {*f*, *l*}, where *f* is an iterator to this element, *l* is `std::next(f)`. Otherwise, {`end()`, `end()`}.

These overloads only participate in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

Observers

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with **this*.

key_comp

```
key_compare key_comp() const;
```

Returns: a copy of the key comparison functor associated with `*this`.

value_comp

```
value_compare value_comp() const;
```

Returns: an object of the `value_compare` class that is used to compare `value_type` objects.

Parallel iteration

Member types `concurrent_set::range_type` and `concurrent_set::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_set::const_range_type` are of type `concurrent_set::const_iterator`, whereas the bounds for a `concurrent_set::range_type` are of type `concurrent_set::iterator`.

range member function

```
range_type range();
const_range_type range() const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provide binary and lexicographical comparison and swap operations on `oneapi::tbb::concurrent_set` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_set` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```
template <typename T, typename Compare, typename Allocator>
void swap( concurrent_set<T, Compare, Allocator>& lhs,
           concurrent_set<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_set<T, Compare, Allocator>& lhs,
                 const concurrent_set<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_set<T, Compare, Allocator>& lhs,
```

(continues on next page)

(continued from previous page)

```

        const concurrent_set<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator<( const concurrent_set<T, Compare, Allocator>& lhs,
               const concurrent_set<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_set<T, Compare, Allocator>& lhs,
               const concurrent_set<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator<=( const concurrent_set<T, Compare, Allocator>& lhs,
                const concurrent_set<T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>=( const concurrent_set<T, Compare, Allocator>& lhs,
                const concurrent_set<T, Compare, Allocator>& rhs );

```

Non-member swap

```

template <typename T, typename Compare, typename Allocator>
void swap( concurrent_set<T, Compare, Allocator>& lhs,
           concurrent_set<T, Compare, Allocator>& rhs );

```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two `oneapi::tbb::concurrent_set` objects are equal if they have the same number of elements and each element in one container is equal to the element in other container on the same position.

```

template <typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_set<T, Compare, Allocator>& lhs,
                const concurrent_set<T, Compare, Allocator>& rhs )

```

Returns: true if lhs is equal to rhs; false, otherwise.

```

template <typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_set<T, Compare, Allocator>& lhs,
                const concurrent_set<T, Compare, Allocator>& rhs )

```

Returns: true if lhs is not equal to rhs; false, otherwise.

Non-member lexicographical comparisons

```
template <typename T, typename Compare, typename Allocator>
bool operator<( const concurrent_set<T, Compare, Allocator>& lhs,
               const concurrent_set<T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *less* than rhs.

```
template <typename T, typename Compare, typename Allocator>
bool operator<=( const concurrent_set<T, Compare, Allocator>& lhs,
                const concurrent_set<T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *less or equal* than rhs.

```
template <typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_set<T, Compare, Allocator>& lhs,
               const concurrent_set<T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *greater* than rhs.

```
template <typename T, typename Compare, typename Allocator>
bool operator>=( const concurrent_set<T, Compare, Allocator>& lhs,
                const concurrent_set<T, Compare, Allocator>& rhs )
```

Returns: true if lhs is lexicographically *greater or equal* than rhs.

Other

Deduction guides

If possible, `concurrent_set` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```
template <typename InputIterator,
         typename Compare = std::less<iterator_value_t<InputIterator>>,
         typename Allocator = tbb::tbb_allocator<iterator_value_t<InputIterator>>>
concurrent_set( InputIterator, InputIterator,
               Compare = Compare(),
               Allocator = Allocator() )
-> concurrent_set<iterator_value_t<InputIterator>,
                 Compare,
                 Allocator>;

template <typename InputIterator,
         typename Allocator>
concurrent_set( InputIterator, InputIterator,
```

(continues on next page)

(continued from previous page)

```

        Allocator )
-> concurrent_set<iterator_value_t<InputIterator>,
        std::less<iterator_value_t<InputIterator>>,
        Allocator>;

template <typename Key,
        typename Compare = std::less<Key>,
        typename Allocator = tbb::tbb_allocator<Key>>
concurrent_set( std::initializer_list<Key>,
        Compare = Compare(),
        Allocator = Allocator() )
-> concurrent_set<Key,
        Compare,
        Allocator>;

template <typename Key,
        typename Allocator>
concurrent_set( std::initializer_list<Key>,
        Allocator )
-> concurrent_set<Key,
        std::less<Key>,
        Allocator>;

```

Where the type alias `iterator_value_t` is defined as follows:

```

template <typename InputIterator>
using iterator_value_t = typename std::iterator_traits<InputIterator>::value_type;

```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `Compare` type does not meet the `Allocator` requirements.

Example

```

#include <oneapi/tbb/concurrent_set.h>
#include <vector>

int main() {
    std::vector<int> v;

    // Deduces cs1 as concurrent_set<int>
    oneapi::tbb::concurrent_set cs1(v.begin(), v.end());

    // Deduces cs2 as concurrent_set<int>
    oneapi::tbb::concurrent_set cs2({1, 2, 3});
}

```

concurrent_multiset

[containers.concurrent_multiset]

`oneapi::tbb::concurrent_multiset` is a class template that represents a sorted sequence of elements. It supports concurrent insertion, lookup, and traversal, but does not support concurrent erasure. In this container, multiple equivalent elements can be stored.

Class Template Synopsis

```
// Defined in header <oneapi/tbb/concurrent_set.h>

namespace oneapi {
    namespace tbb {

        template <typename T,
                 typename Compare = std::less<T>,
                 typename Allocator = tbb_allocator<T>>
        class concurrent_multiset {
        public:
            using key_type = T;
            using value_type = T;

            using size_type = <implementation-defined unsigned integer type>;
            using difference_type = <implementation-defined signed integer type>;

            using key_compare = Compare;
            using value_compare = Compare;

            using allocator_type = Allocator;

} // namespace tbb
} // namespace oneapi

```

Requirements:

- The expression `std::allocator_traits<Allocator>::destroy(m, val)`, where `m` is an object of the type `Allocator` and `val` is an object of the type `value_type`, should be well-formed. Member functions can impose stricter requirements depending on the type of the operation.
- The type `Compare` must meet the `Compare` requirements from the [alg.sorting] ISO C++ Standard section.
- The type `Allocator` must meet the `Allocator` requirements from the [allocator.requirements] ISO C++ Standard section.

Member functions**Construction, destruction, copying****Empty container constructors**

```

concurrent_multiset();

explicit concurrent_multiset( const key_compare& comp,
                             const allocator_type& alloc = allocator_type() );

explicit concurrent_multiset( const allocator_type& alloc );

```

Constructs an empty `concurrent_multiset`.

If provided, uses the comparison function object `comp` for all `key_type` comparisons and the allocator `alloc` to allocate the memory.

Constructors from the sequence of elements

```

template <typename InputIterator>
concurrent_multiset( InputIterator first, InputIterator last,
                    const key_compare& comp = key_compare(),
                    const allocator_type& alloc = allocator_type() );

template <typename InputIterator>
concurrent_multiset( InputIterator first, InputIterator last,
                    const allocator_type& alloc = allocator_type() );

```

Constructs the `concurrent_multiset`, which contains all elements from the half-open interval `[first, last)`.

If provided, uses the comparison function object `comp` for all `key_type` comparisons and the allocator `alloc` to allocate the memory.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from the [input.iterators] ISO C++ Standard section.

```
concurrent_multiset( std::initializer_list<value_type> init, const key_compare&
↳ comp = key_compare(),
                    const allocator_type& alloc = allocator_type() );
```

Equivalent to `concurrent_multiset(init.begin(), init.end(), comp, alloc)`.

```
concurrent_multiset( std::initializer_list<value_type> init,
                    const allocator_type& alloc );
```

Equivalent to `concurrent_multiset(init.begin(), init.end(), alloc)`.

Copying constructors

```
concurrent_multiset( const concurrent_multiset& other );

concurrent_multiset( const concurrent_multiset& other, const allocator_type&
↳ alloc );
```

Constructs a copy of `other`.

If the allocator argument is not provided, it is obtained by calling `std::allocator_traits<allocator_type>::select_on_container_copy_construction(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Moving constructors

```
concurrent_multiset( concurrent_multiset&& other );

concurrent_multiset( concurrent_multiset&& other, const allocator_type& alloc
↳ );
```

Constructs a *concurrent_multiset* with the contents of `other` using move semantics.

`other` is left in a valid, but unspecified state.

If the allocator argument is not provided, it is obtained by calling `std::move(other.get_allocator())`.

The behavior is undefined in case of concurrent operations with `other`.

Destructor

```
~concurrent_multiset();
```

Destroys the `concurrent_multiset`. Calls destructors of the stored elements and deallocates the used storage.

The behavior is undefined in case of concurrent operations with `*this`.

Assignment operators

```
concurrent_multiset& operator=( const concurrent_multiset& other );
```

Replaces all elements in `*this` by the copies of the elements in `other`.

Copy-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_copy_assignment::is true`.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_multiset& operator=( concurrent_multiset&& other );
```

Replaces all elements in `*this` by the elements in `other` using move semantics.

`other` is left in a valid, but unspecified state.

Move-assigns allocators if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment::is true`.

The behavior is undefined in case of concurrent operations with `*this` and `other`.

Returns: a reference to `*this`.

```
concurrent_multiset& operator=( std::initializer_list<value_type> init );
```

Replaces all elements in `*this` by the elements in `init`.

If `init` contains multiple elements with equal keys, it is unspecified which element would be inserted.

The behavior is undefined in case of concurrent operations with `*this`.

Returns: a reference to `*this`.

Iterators

The types `concurrent_multiset::iterator` and `concurrent_multiset::const_iterator` meet the requirements of `ForwardIterator` from the [forward.iterators] ISO C++ standard section.

begin and cbegin

```
iterator begin();  
const_iterator begin() const;  
const_iterator cbegin() const;
```

Returns: an iterator to the first element in the container.

end and cend

```
iterator end();  
const_iterator end() const;  
const_iterator cend() const;
```

Returns: an iterator to the element that follows the last element in the container.

Size and capacity

empty

```
bool empty() const;
```

Returns: true if the container is empty; false, otherwise.

The result may differ from the actual container state in case of pending concurrent insertions.

size

```
size_type size() const;
```

Returns: the number of elements in the container.

The result may differ from the actual container size in case of pending concurrent insertions.

max_size

```
size_type max_size() const;
```

Returns: the maximum number of elements that container can hold.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other, lookup methods and while traversing the container.

Inserting values

```
std::pair<iterator, bool> insert( const value_type& value );
```

Inserts the value `value` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, const value_type& other );
```

Inserts the value `value` into the container.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

Returns: an iterator to the inserted element.

Requirements: the type `value_type` must meet the `CopyInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
std::pair<iterator, bool> insert( value_type&& value );
```

Inserts the value `value` into the container using move semantics.

`value` is left in a valid, but unspecified state.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

```
iterator insert( const_iterator hint, value_type&& other );
```

Inserts the value `value` into the container using move semantics.

Optionally uses the parameter `hint` as a suggestion to where the element should be placed.

`value` is left in a valid, but unspecified state.

Returns: an iterator to the inserted element.

Requirements: the type `value_type` must meet the `MoveInsertable` requirements from the [container.requirements] ISO C++ Standard section.

Inserting sequences of elements

```
template <typename InputIterator>
void insert( InputIterator first, InputIterator last );
```

Inserts all items from the half-open interval `[first, last)` into the container.

Requirements: the type `InputIterator` must meet the requirements of *InputIterator* from the `[input.iterators]` ISO C++ Standard section.

```
void insert( std::initializer_list<value_type> init );
```

Equivalent to `insert(init.begin(), init.end())`.

Inserting nodes

```
std::pair<iterator, bool> insert( node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, inserts the node owned by `nh` into the container.

`nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

```
iterator insert( const_iterator hint, node_type&& nh );
```

If the node handle `nh` is empty, does nothing.

Otherwise, inserts the node owned by `nh` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

`nh` is left in an empty state.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `nh` is not empty and `get_allocator() != nh.get_allocator()`.

Returns: an iterator pointing to the inserted element.

Emplacing elements

```
template <typename... Args>
std::pair<iterator, bool> emplace( Args&&... args );
```

Inserts an element, constructed in-place from `args` into the container.

Returns: `std::pair<iterator, bool>`, where `iterator` points to the inserted element. Boolean value is always `true`.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

```
template <typename... Args>
iterator emplace_hint( const_iterator hint, Args&&... args );
```

Inserts an element constructed in-place from `args` into the container.

Optionally uses the parameter `hint` as a suggestion to where the node should be placed.

Returns: an iterator to the inserted element.

Requirements: the type `value_type` must meet the `EmplaceConstructible` requirements from the [container.requirements] ISO C++ section.

Merging containers

```
template <typename SrcCompare>
void merge( concurrent_set<T, SrcCompare, Allocator>& source );

template <typename SrcCompare>
void merge( concurrent_set<T, SrcCompare, Allocator>&& source );

template <typename SrcCompare>
void merge( concurrent_multiset<T, SrcCompare, Allocator>& source );

template <typename SrcCompare>
void merge( concurrent_multiset<T, SrcCompare, Allocator>&& source );
```

Transfers all elements from `source` to `*this`.

No copy or move constructors of `value_type` are performed.

The behavior is undefined if `get_allocator() != source.get_allocator()`.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these member functions with other (either concurrently safe) methods.

Clearing

```
void clear();
```

Removes all elements from the container.

Erasing elements

```
iterator unsafe_erase( const_iterator pos );
iterator unsafe_erase( iterator pos );
```

Removes the element pointed to by `pos` from the container.

Invalidates all iterators and references to the removed element.

Returns: iterator that follows the removed element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
size_type unsafe_erase( const key_type& key );
```

Removes all elements equivalent to `key` if they exist in the container.

Invalidates all iterators and references to the removed element.

Returns: the number of removed elements.

```
template <typename K>
size_type unsafe_erase( const K& key );
```

Removes all elements that are equivalent to `key` if they exist in the container.

Invalidates all iterators and references to the removed element.

This overload only participates in overload resolution if all of the following statements are true:

- The qualified-id `key_compare::is_transparent` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the number of removed elements.

Erasing sequences

```
iterator unsafe_erase( const_iterator first, const_iterator last );
```

Removes all elements from the half-open interval `[first, last)` from the container.

Returns: iterator that follows the last removed element.

Requirements: the range `[first, last)` must be a valid subrange in `*this`.

Extracting nodes

```
node_type unsafe_extract( iterator pos );
node_type unsafe_extract( const_iterator pos );
```

Transfers ownership of the element pointed to by `pos` from the container to the node handle.

No copy or move constructors of `value_type` are performed.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element.

Requirements: the iterator `pos` should be valid, dereferenceable and point to the element in `*this`.

```
node_type unsafe_extract( const key_type& key );
```

If an element equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

If there are multiple elements equivalent to `key`, it is unspecified which element should be transferred.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

Returns: the node handle that owns the extracted element or an empty node handle if an element equivalent to `key` was not found.

```
template <typename K>
node_type unsafe_extract( const K& key );
```

If an element that is equivalent to `key` exists, transfers ownership of this element from the container to the node handle.

No copy or move constructors of `value_type` are performed.

If there are multiple elements equivalent to `key`, it is unspecified which element should be transferred.

Invalidates all iterators to the extracted element. Pointers and references to the extracted element remain valid.

This overload only participates in overload resolution if all of the following statements are `true`:

- The qualified-id `key_compare::is_transparent` is valid and denotes a type.
- `std::is_convertible<K, iterator>::value` is false.
- `std::is_convertible<K, const_iterator>::value` is false.

Returns: the node handle that owns the extracted element or an empty node handle if an element equivalent to `key` was not found.

swap

```
void swap( concurrent_multiset& other );
```

Swaps contents of `*this` and `other`.

Swaps allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is true.

Otherwise, if `get_allocator() != other.get_allocator()`, the behavior is undefined.

Lookup

All methods in this section can be executed concurrently with each other, concurrently-safe modifiers and while traversing the container.

count

```
size_type count( const key_type& key );
```

Returns: the number of elements equivalent to `key`.

```
template <typename K>
size_type count( const K& key );
```

Returns: the number of elements that are equivalent to `key`.

This overload only participates in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

find

```
iterator find( const key_type& key );
const_iterator find( const key_type& key ) const;
```

Returns: an iterator to the element equivalent to `key` or `end()` if no such element exists.

If there are multiple elements equivalent to `key`, it is unspecified which element should be found.

```
template <typename K>
iterator find( const K& key );
```

```
template <typename K>
const_iterator find( const K& key ) const;
```

Returns: an iterator to the element that is equivalent to `key`, or `end()` if no such element exists.

If there are multiple elements that are equivalent to `key`, it is unspecified which element should be found.

These overloads only participate in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

contains

```
bool contains( const key_type& key ) const;
```

Returns: true if at least one element equivalent to `key` exists in the container; false, otherwise.

```
template <typename K>
bool contains( const K& key ) const;
```

Returns: true if at least one element that is equivalent to `key` exists in the container; false, otherwise.

This overload participates in overload resolution only if qualified-id `key_compare::is_transparent` is valid and denotes a type.

lower_bound

```
iterator lower_bound( const key_type& key );
const_iterator lower_bound( const key_type& key ) const;
```

Returns: an iterator to the first element in the container that is *not less* than `key`.

```
template <typename K>
iterator lower_bound( const K& key )

template <typename K>
const_iterator lower_bound( const K& key ) const
```

Returns: an iterator to the first element in the container that is *not less* than `key`.

These overloads only participate in overload resolution if qualified-id `key_compare::is_transparent` is valid and denotes a type.

upper_bound

```
iterator upper_bound( const key_type& key );

const_iterator upper_bound( const key_type& key ) const;
```

Returns: an iterator to the first element in the container that compares *greater* than *key*.

```
template <typename K>
iterator upper_bound( const K& key );

template <typename K>
const_iterator upper_bound( const K& key ) const;
```

Returns: an iterator to the first element in the container that compares greater than *key*.

These overloads participate in overload resolution only if qualified-id `key_compare::is_transparent` is valid and denotes a type.

equal_range

```
std::pair<iterator, iterator> equal_range( const key_type& key );

std::pair<const_iterator, const_iterator> equal_range( const key_type& key )
↳const;
```

Returns: if at least one element equivalent to *key* exists, a pair of iterators {*f*, *l*}, where *f* is an iterator to the first element equivalent to *key*, *l* is an iterator to the element that follows the last element equivalent to *key*. Otherwise, {`end()`, `end()`}.

```
template <typename K>
std::pair<iterator, iterator> equal_range( const K& key )

template <typename K>
std::pair<const_iterator, const_iterator> equal_range( const K& key )
```

Returns: if at least one element that is equivalent to *key* exists, a pair of iterators {*f*, *l*}, where *f* is an iterator to the first element that is equivalent to *key*, *l* is an iterator to the element that follows the last element that is equivalent to *key*. Otherwise, {`end()`, `end()`}.

These overloads participate in overload resolution only if qualified-id `key_compare::is_transparent` is valid and denotes a type.

Observers

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator associated with `*this`.

key_comp

```
key_compare key_comp() const;
```

Returns: a copy of the key comparison functor associated with `*this`.

value_comp

```
value_compare value_comp() const;
```

Returns: an object of the `value_compare` class that is used to compare `value_type` objects.

Parallel iteration

Member types `concurrent_multiset::range_type` and `concurrent_multiset::const_range_type` meet the *ContainerRange requirements*.

These types differ only in that the bounds for a `concurrent_multiset::const_range_type` are of type `concurrent_multiset::const_iterator`, whereas the bounds for a `concurrent_multiset::range_type` are of type `concurrent_multiset::iterator`.

range member function

```
range_type range();
const_range_type range() const;
```

Returns: a range object representing all elements in the container.

Non-member functions

These functions provides binary and lexicographical comparison and swap operations on `oneapi::tbb::concurrent_multiset` objects.

The exact namespace where these functions are defined is unspecified, as long as they may be used in respective comparison operations. For example, an implementation may define the classes and functions in the same internal namespace and define `oneapi::tbb::concurrent_multiset` as a type alias for which the non-member functions are reachable only via argument dependent lookup.

```

template <typename T, typename Compare, typename Allocator>
void swap( concurrent_multiset<T, Compare, Allocator>& lhs,
           concurrent_multiset<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_multiset<T, Compare, Allocator>& lhs,
                 const concurrent_multiset<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_multiset<T, Compare, Allocator>& lhs,
                 const concurrent_multiset<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator<( const concurrent_multiset<T, Compare, Allocator>& lhs,
                const concurrent_multiset<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_multiset<T, Compare, Allocator>& lhs,
                const concurrent_multiset<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator<=( const concurrent_multiset<T, Compare, Allocator>& lhs,
                 const concurrent_multiset<T, Compare, Allocator>& rhs );

template <typename T, typename Compare, typename Allocator>
bool operator>=( const concurrent_multiset<T, Compare, Allocator>& lhs,
                 const concurrent_multiset<T, Compare, Allocator>& rhs );

template <typename Key, typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_multiset<T, Compare, Allocator>& lhs,
                 const concurrent_multiset<T, Compare, Allocator>& rhs );

```

Non-member swap

```

template <typename T, typename Compare, typename Allocator>
void swap( concurrent_multiset<T, Compare, Allocator>& lhs,
           concurrent_multiset<T, Compare, Allocator>& rhs );

```

Equivalent to `lhs.swap(rhs)`.

Non-member binary comparisons

Two `oneapi::tbb::concurrent_multiset` objects are equal if they have the same number of elements and each element in one container is equal to the element in other container on the same position.

```

template <typename T, typename Compare, typename Allocator>
bool operator==( const concurrent_multiset<T, Compare, Allocator>& lhs,
                 const concurrent_multiset<T, Compare, Allocator>& rhs )

```

Returns: true if lhs is equal to rhs; false, otherwise.

```

template <typename T, typename Compare, typename Allocator>
bool operator!=( const concurrent_multiset<T, Compare, Allocator>& lhs,
                 const concurrent_multiset<T, Compare, Allocator>& rhs )

```

Returns: true if lhs is not equal to rhs; false, otherwise.

Non-member lexicographical comparisons

```

template <typename T, typename Compare, typename Allocator>
bool operator<( const concurrent_multiset<T, Compare, Allocator>& lhs,
               const concurrent_multiset<T, Compare, Allocator>& rhs )

```

Returns: true if lhs is lexicographically *less* than rhs.

```

template <typename T, typename Compare, typename Allocator>
bool operator<=( const concurrent_multiset<T, Compare, Allocator>& lhs,
                const concurrent_multiset<T, Compare, Allocator>& rhs )

```

Returns: true if lhs is lexicographically *less or equal* than rhs.

```

template <typename T, typename Compare, typename Allocator>
bool operator>( const concurrent_multiset<T, Compare, Allocator>& lhs,
               const concurrent_multiset<T, Compare, Allocator>& rhs )

```

Returns: true if lhs is lexicographically *greater* than rhs.

```

template <typename T, typename Compare, typename Allocator>
bool operator>=( const concurrent_multiset<T, Compare, Allocator>& lhs,
                const concurrent_multiset<T, Compare, Allocator>& rhs )

```

Returns: true if lhs is lexicographically *greater or equal* than rhs.

Other

Deduction guides

If possible, `concurrent_multiset` constructors support class template argument deduction (since C++17). Copy and move constructors, including constructors with an explicit `allocator_type` argument, provide implicitly-generated deduction guides. In addition, the following explicit deduction guides are provided:

```

template <typename InputIterator,
         typename Compare = std::less<iterator_value_t<InputIterator>>,
         typename Allocator = tbb::tbb_allocator<iterator_value_t<InputIterator>>>
concurrent_multiset( InputIterator, InputIterator,
                    Compare = Compare(),
                    Allocator = Allocator() )

```

(continues on next page)

(continued from previous page)

```

-> concurrent_multiset<iterator_value_t<InputIterator>,
                       Compare,
                       Allocator>;

template <typename InputIterator,
          typename Allocator>
concurrent_multiset( InputIterator, InputIterator,
                    Allocator )
-> concurrent_multiset<iterator_value_t<InputIterator>,
                       std::less<iterator_value_t<InputIterator>>,
                       Allocator>;

template <typename Key,
          typename Compare = std::less<Key>,
          typename Allocator = tbb::tbb_allocator<Key>>
concurrent_multiset( std::initializer_list<Key>,
                    Compare = Compare(),
                    Allocator = Allocator() )
-> concurrent_multiset<Key,
                       Compare,
                       Allocator>;

template <typename Key,
          typename Allocator>
concurrent_multiset( std::initializer_list<Key>,
                    Allocator )
-> concurrent_multiset<Key,
                       std::less<Key>,
                       Allocator>;

```

Where the type alias `iterator_value_t` is defined as follows:

```

template <typename InputIterator>
using iterator_value_t = typename std::iterator_traits<InputIterator>::value_type;

```

These deduction guides only participate in the overload resolution if the following requirements are met:

- The `InputIterator` type meets the `InputIterator` requirements described in the [input.iterators] section of the ISO C++ Standard.
- The `Allocator` type meets the `Allocator` requirements described in the [allocator.requirements] section of the ISO C++ Standard.
- The `Compare` type does not meet the `Allocator` requirements.

Example

```

#include <oneapi/tbb/concurrent_set.h>
#include <vector>

int main() {
    std::vector<int> v;

    // Deduces cs1 as concurrent_multiset<int>

```

(continues on next page)

(continued from previous page)

```

oneapi::tbb::concurrent_multiset cs1(v.begin(), v.end());

// Deduces cs2 as concurrent_multiset<int>
oneapi::tbb::concurrent_multiset cs2({1, 2, 3});
}

```

Auxiliary classes

tbb_hash_compare

[containers.tbb_hash_compare]

oneapi::tbb::tbb_hash_compare is a class template for hash support. Use it with the oneapi::tbb::concurrent_hash_map associative container to calculate hash codes and compare keys for equality.

tbb_hash_compare meets the *HashCompare requirements*.

Class Template Synopsis

```

// Defined in header <oneapi/tbb/concurrent_hash_map.h>

namespace oneapi {
    namespace tbb {

        template <typename Key>
        class tbb_hash_compare {
            static std::size_t hash( const Key& k );
            static bool equal( const Key& k1, const Key& k2 );
        }; // class tbb_hash_compare

    } // namespace tbb
} // namespace oneapi

```

Member functions

```

static std::size_t hash( const Key& k );

```

Returns: a hash code for a key k.

```

static bool equal( const Key& k1, const Key& k2 );

```

Equivalent to `k1 == k2`.

Returns: true if the keys are equal; false, otherwise.

Node handles

[containers.node_handles]

Concurrent associative containers (`concurrent_map`, `concurrent_multimap`, `concurrent_set`, `concurrent_multiset`, `concurrent_unordered_map`, `concurrent_unordered_multimap`, `concurrent_unordered_set`, and `concurrent_unordered_multiset`) store elements in individually allocated, connected nodes. These containers support data transfer between containers with compatible node types by changing the connections without copying or moving the actual data.

Class synopsis

```
class node-handle { // Exposition-only name
public:
    using key_type = <container-specific>; // Only for maps
    using mapped_type = <container-specific>; // Only for maps
    using value_type = <container-specific>; // Only for sets
    using allocator_type = <container-specific>;

    node-handle();
    node-handle( node-handle&& other );

    ~node-handle();

    node-handle& operator=( node-handle&& other );

    void swap( node-handle& nh );

    bool empty() const;
    explicit operator bool() const;

    key_type& key() const; // Only for maps
    mapped_type& mapped() const; // Only for maps
    value_type& value() const; // Only for sets

    allocator_type get_allocator() const;
};
```

A node handle is a container-specific move-only nested type (exposed as `container::node_type`) that represents a node outside of any container instance. It allows reading and modifying the data stored in the node, and inserting the node into a compatible container instance. The following containers have compatible node types and may exchange nodes:

- `concurrent_map` and `concurrent_multimap` with the same `key_type`, `mapped_type` and `allocator_type`.
- `concurrent_set` and `concurrent_multiset` with the same `value_type` and `allocator_type`.
- `concurrent_unordered_map` and `concurrent_unordered_multimap` with the same `key_type`, `mapped_type` and `allocator_type`.
- `concurrent_unordered_set` and `concurrent_unordered_multiset` with the same `value_type` and `allocator_type`.

Default or moved-from node handles are *empty* and do not represent a valid node. A non-empty node handle is typically created when a node is extracted out of a container, for example, with the `unsafe_extract` method. It stores the node along with a copy of the container's allocator. Upon assignment or destruction a non-empty node handle destroys the stored data and deallocates the node.

Member functions

Constructors

```
node-handle();
```

Constructs an empty node handle.

```
node-handle( node-handle&& other );
```

Constructs a node handle that takes ownership of the node from `other`.

`other` is left in an empty state.

Assignment

```
node-handle& operator=( node-handle&& other );
```

Transfers ownership of the node from `other` to `*this`. If `*this` was not empty before transferring, destroys and deallocates the stored node.

Move assigns the stored allocator if `std::allocator_traits<allocator_type>::propagate_on_container_move_assignment` is `true`.

`other` is left in an empty state.

Destructor

```
~node-handle();
```

Destroys the node handle. If it is not empty, destroys and deallocates the owned node.

Swap

```
void swap( node-handle& other )
```

Exchanges the nodes owned by `*this` and `other`.

Swaps the stored allocators if `std::allocator_traits<allocator_type>::propagate_on_container_swap::value` is `true`.

State

```
bool empty() const;
```

Returns: true if the node handle is empty, false otherwise.

```
explicit operator bool() const;
```

Equivalent to !empty().

Access to the stored element

```
key_type& key() const;
```

Available only for map node handles.

Returns: a reference to the key of the element stored in the owned node.

The behavior is undefined if the node handle is empty.

```
mapped_type& mapped() const;
```

Available only for map node handles.

Returns: a reference to the value of the element stored in the owned node.

The behavior is undefined if the node handle is empty.

```
value_type& value() const;
```

Available only for set node handles.

Returns: a reference to the element stored in the owned node.

The behavior is undefined if the node handle is empty.

get_allocator

```
allocator_type get_allocator() const;
```

Returns: a copy of the allocator stored in the node handle.

The behavior is undefined if the node handle is empty.

9.2.6 Thread Local Storage

[thread_local_storage]

oneAPI Threading Building Blocks provides class templates for thread local storage (TLS). Each provides a thread-local element per thread and lazily creates elements on demand.

combinable

[tls.combinable]

A class template for holding thread-local values during a parallel computation that will be merged into a final value.

A combinable provides each thread with its own instance of type T.

```
// Defined in header <oneapi/tbb/combinable.h>

namespace oneapi {
namespace tbb {
    template <typename T>
    class combinable {
    public:
        combinable();

        combinable(const combinable& other);
        combinable(combinable&& other);

        template <typename FInit>
        explicit combinable(FInit finit);

        ~combinable();

        combinable& operator=( const combinable& other);
        combinable& operator=( combinable&& other);

        void clear();

        T& local();
        T& local(bool & exists);

        template<typename BinaryFunc> T combine(BinaryFunc f);
        template<typename UnaryFunc> void combine_each(UnaryFunc f);
    };
} // namespace tbb
} // namespace oneapi
```

Member functions

`combinable()`

Constructs `combinable` such that thread-local instances of `T` will be default-constructed.

template<typename **FInit**>

explicit `combinable(FInit finit)`

Constructs `combinable` such that thread-local elements will be created by copying the result of `finit()`.

Caution: The expression `finit()` must be safe to evaluate concurrently by multiple threads. It is evaluated each time a new thread-local element is created.

`combinable(const combinable &other)`

Constructs a copy of `other`, so that it has copies of each element in `other` with the same thread mapping.

`combinable(combinable &&other)`

Constructs `combinable` by moving the content of `other` intact. `other` is left in an unspecified state but can be safely destroyed.

`~combinable()`

Destroys all elements in `*this`.

`combinable &operator=(const combinable &other)`

Sets `*this` to be a copy of `other`. Returns a reference to `*this`.

`combinable &operator=(combinable &&other)`

Moves the content of `other` to `*this` intact. `other` is left in an unspecified state but can be safely destroyed. Returns a reference to `*this`.

`void clear()`

Removes all elements from `*this`.

`T &local()`

If an element does not exist for the current thread, creates it.

Returns: Reference to thread-local element.

`T &local(bool &exists)`

Similar to `local()`, except that `exists` is set to true if an element was already present for the current thread; false, otherwise.

Returns: Reference to thread-local element.

template<typename **BinaryFunc**>

`T combine(BinaryFunc f)`

Requires: A `BinaryFunc` must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard. Specifically, the type should be an associative binary functor with the signature `T BinaryFunc(T, T)` or `T BinaryFunc(const T&, const T&)`. A `T` type must be the same as a corresponding template parameter for the `combinable` object.

Effects: Computes a reduction over all elements using binary functor `f`. All evaluations of `f` are done sequentially in the calling thread. If there are no elements, creates the result using the same rules as for creating a new element.

Returns: Result of the reduction.

template<typename **UnaryFunc**>

`void combine_each(UnaryFunc f)`

Requires: An `UnaryFunc` must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard. Specifically, the type should be an unary functor with the one of the signatures:

void UnaryFunc(T), void UnaryFunc(T&), or void UnaryFunc(const T&) A T type must be the same as a corresponding template parameter for the enumerable_thread_specific object.

Effects: Evaluates $f(x)$ for each thread-local element x in `*this`. All evaluations are done sequentially in the calling thread.

Note: Methods of class `combinable` are not thread-safe, except for `local`.

enumerable_thread_specific

[tls.enumerable_thread_specific]

A class template for thread local storage (TLS).

```
// Defined in header <oneapi/tbb/enumerable_thread_specific.h>

namespace oneapi {
namespace tbb {

    enum ets_key_usage_type {
        ets_key_per_instance,
        ets_no_key,
        ets_suspend_aware
    };

    template <typename T,
              typename Allocator=cache_aligned_allocator<T>,
              ets_key_usage_type ETS_key_type=ets_no_key >
    class enumerable_thread_specific {
    public:
        // Basic types
        using value_type = T;
        using reference = T&;
        using const_reference = const T&;
        using pointer = T*;
        using size_type = /* implementation-defined */;
        using difference_type = /* implementation-defined */;
        using allocator_type = Allocator;

        // Iterator types
        using iterator = /* implementation-defined */;
        using const_iterator = /* implementation-defined */;

        // Parallel range types
        using range_type = /* implementation-defined */;
        using const_range_type = /* implementation-defined */;

        // Construction
        enumerable_thread_specific();
        template <typename Finit>
        explicit enumerable_thread_specific( Finit finit );
        explicit enumerable_thread_specific( const T& exemplar );
    };
};
}
```

(continues on next page)

(continued from previous page)

```

explicit enumerable_thread_specific( T&& exemplar );
template <typename... Args>
enumerable_thread_specific( Args&&... args );

// Destruction
~enumerable_thread_specific();

// Copy constructors
enumerable_thread_specific( const enumerable_thread_specific& other);
template<typename Alloc, ets_key_usage_type Cachetype>
enumerable_thread_specific( const enumerable_thread_specific<T, Alloc, Cachetype>
↪ & other);
// Copy assignments
enumerable_thread_specific& operator=( const enumerable_thread_specific& other );
template<typename Alloc, ets_key_usage_type Cachetype>
enumerable_thread_specific& operator=( const enumerable_thread_specific<T, Alloc,
↪ Cachetype>& other );

// Move constructors
enumerable_thread_specific( enumerable_thread_specific&& other);
template<typename Alloc, ets_key_usage_type Cachetype>
enumerable_thread_specific( enumerable_thread_specific<T, Alloc, Cachetype>&&
↪ other);
// Move assignments
enumerable_thread_specific& operator=( enumerable_thread_specific&& other );
template<typename Alloc, ets_key_usage_type Cachetype>
enumerable_thread_specific& operator=( enumerable_thread_specific<T, Alloc,
↪ Cachetype>&& other );

// Other whole container operations
void clear();

// Concurrent operations
reference local();
reference local( bool& exists );
size_type size() const;
bool empty() const;

// Combining
template<typename BinaryFunc> T combine( BinaryFunc f );
template<typename UnaryFunc> void combine_each( UnaryFunc f );

// Parallel iteration
range_type range( size_t grainsize=1 );
const_range_type range( size_t grainsize=1 ) const;

// Iterators
iterator begin();
iterator end();
const_iterator begin() const;
const_iterator end() const;
};

```

(continues on next page)

(continued from previous page)

```

} // namespace tbb
} // namespace oneapi

```

A class template `enumerable_thread_specific` provides TLS for elements of type `T`. A class template `enumerable_thread_specific` acts as a container by providing iterators and ranges across all of the thread-local elements.

The thread-local elements are created lazily. A freshly constructed `enumerable_thread_specific` has no elements. When a thread requests access to an `enumerable_thread_specific`, it creates an element corresponding to that thread. The number of elements is equal to the number of distinct threads that have accessed the `enumerable_thread_specific` and not necessarily the number of threads in use by the application. Clearing an `enumerable_thread_specific` removes all its elements.

Use the `ETS_key_usage_type` parameter type to select an underlying implementation.

Caution: `enumerable_thread_specific` uses the OS-specific value returned by `std::this_thread::get_id()` to identify threads. This value is not guaranteed to be unique except for the life of the thread. A newly created thread may get an OS-specific ID equal to that of an already destroyed thread. The number of elements of the `enumerable_thread_specific` may therefore be less than the number of actual distinct threads that have called `local()`, and the element returned by the first reference by a thread to the `enumerable_thread_specific` may not be newly-constructed.

Member functions

Construction, destruction, copying

Empty container constructors

```
enumerable_thread_specific();
```

Constructs an `enumerable_thread_specific` where each thread-local element will be default-constructed.

```
template<typename Finit> explicit enumerable_thread_specific( Finit finit );
```

Constructs an `enumerable_thread_specific` such that any thread-local element will be created by copying the result of `finit()`.

Note: The expression `finit()` must be safe to evaluate concurrently by multiple threads. It is evaluated each time a thread-local element is created.

```
explicit enumerable_thread_specific( const T& exemplar );
```

Constructs an `enumerable_thread_specific` where each thread-local element will be copy-constructed from `exemplar`.

```
explicit enumerable_thread_specific( T&& exemplar );
```

Constructs an `enumerable_thread_specific` object, move constructor of `T` can be used to store `exemplar` internally; however, thread-local elements are always copy-constructed.

```
template <typename... Args> enumerable_thread_specific( Args&&... args );
```

Constructs `enumerable_thread_specific` such that any thread-local element will be constructed by invoking `T(args...)`.

Note: This constructor does not participate in overload resolution if the type of the first argument in `args...` is `T`, or `enumerable_thread_specific<T>`, or `foo()` is a valid expression for a value `foo` of that type.

Copying constructors

```
enumerable_thread_specific ( const enumerable_thread_specific& other );
```

```
template<typename Alloc, ets_key_usage_type Cachetype> enumerable_thread_specific( const_␣
↳enumerable_thread_specific <T, Alloc, Cachetype>& other );
```

Constructs an `enumerable_thread_specific` as a copy of `other`. The values are copy-constructed from the values in `other` and have same thread correspondence.

Moving constructors

```
enumerable_thread_specific ( enumerable_thread_specific&& other )
```

Constructs an `enumerable_thread_specific` by moving the content of `other` intact. `other` is left in an unspecified state, but can be safely destroyed.

```
template<typename Alloc, ets_key_usage_type Cachetype> enumerable_thread_specific(␣
↳enumerable_thread_specific <T, Alloc, Cachetype>&& other )
```

Constructs an `enumerable_thread_specific` using per-element move construction from the values in `other`, and keeping their thread correspondence. `other` is left in an unspecified state, but can be safely destroyed.

Destructor

```
~enumerable_thread_specific()
```

Destroys all elements in `*this`. Destroys any native TLS keys that were created for this instance.

Assignment operators

```
enumerable_thread_specific& operator=( const enumerable_thread_specific& other );
```

Copies the content of `other` to `*this`. Returns a reference to `this*`.

```
template<typename Alloc, ets_key_usage_type Cachetype>
enumerable_thread_specific& operator=( const enumerable_thread_specific<T, Alloc,␣
↳Cachetype>& other );
```

Copies the content of `other` to `*this`. Returns a reference to `this*`.

Note: The allocator and key usage specialization is unchanged by this call.

```
enumerable_thread_specific& operator=( enumerable_thread_specific&& other );
```

Moves the content of `other` to `*this` intact. An `other` is left in an unspecified state, but can be safely destroyed. Returns a reference to `this*`.

```
template<typename Alloc, ets_key_usage_type Cachetype>
enumerable_thread_specific& operator=( enumerable_thread_specific<T, Alloc, Cachetype>&&
↳ other );
```

Moves the content of `other` to `*this` using per-element move construction and keeping thread correspondence. An `other` is left in an unspecified state, but can be safely destroyed. Returns a reference to `this*`.

Note: The allocator and key usage specialization is unchanged by this call.

Concurrently safe modifiers

All member functions in this section can be performed concurrently with each other.

reference `local()`

If there is no current element corresponding to the current thread, this method constructs a new element. A new element is copy-constructed if an exemplar was provided to the constructor for `*this`; otherwise, a new element is default-constructed.

Returns: A reference to the element of `*this` that corresponds to the current thread.

reference `local(bool &exists)`

Similar to `local()`, except that `exists` is set to true if an element was already present for the current thread; false, otherwise.

Returns: Reference to the thread-local element.

Concurrently unsafe modifiers

All member functions in this section can only be performed serially. The behavior is undefined in case of concurrent execution of these methods with other (either concurrently safe) methods.

`clear`

```
void clear();
```

Destroys all elements in `*this`.

Size and capacity

size_type **size**() const

Returns the number of elements in **this*. The value is equal to the number of distinct threads that have called `local()` after **this* was constructed or most recently cleared.

bool **empty**() const

Returns `true` if the container is empty; `false`, otherwise.

Iteration

Class template `enumerable_thread_specific` supports random access iterators, which enable iteration over the set of all elements in the container.

iterator **begin**()

Returns iterator pointing to the beginning of the set of elements.

iterator **end**()

Returns iterator pointing to the end of the set of elements.

const_iterator **begin**() const

Returns *const_iterator* pointing to the beginning of the set of elements.

const_iterator **end**() const

Returns *const_iterator* pointing to the end of the set of elements.

Class template `enumerable_thread_specific` supports `const_range_type` and `range_type` types, which model the *ContainerRange requirement*. The types differ only in that the bounds for a `const_range_type` are of type `const_iterator`, whereas the bounds for a `range_type` are of type `iterator`.

`const_range_type` **range**(size_t grainsize = 1) const

Returns: A `const_range_type` representing all elements in **this*. The parameter `grainsize` is in units of elements.

`range_type` **range**(size_t grainsize = 1)

Returns: A `range_type` representing all elements in **this*. The parameter `grainsize` is in units of elements.

Combining

The member functions in this section iterate across the entire container sequentially in the calling thread.

template<typename **BinaryFunc**>

T **combine**(*BinaryFunc* f)

Requires: A `BinaryFunc` must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard. Specifically, the type should be an associative binary functor with the signature `T BinaryFunc(T, T)` or `T BinaryFunc(const T&, const T&)`. A `T` type must be the same as a corresponding template parameter for `enumerable_thread_specific` object.

Effects: Computes reduction over all elements using binary functor `f`. If there are no elements, creates the result using the same rules as for creating a thread-local element.

Returns: Result of the reduction.

template<typename **UnaryFunc**>

void **combine_each**(*UnaryFunc* f)

Requires: An `UnaryFunc` must meet the *Function Objects* requirements described in the [function.objects] section of the ISO C++ standard. Specifically, the type should be an unary functor with one of signatures: `void`

UnaryFunc(T), void UnaryFunc(T&), or void UnaryFunc(const T&) A T type must be the same as a corresponding template parameter for the enumerable_thread_specific object.

Effects: Evaluates $f(x)$ for each instance x of T in `*this`.

Non-member types and constants

enum ets_key_usage_type::ets_key_per_instance

Enumeration parameter type used to select an implementation that consumes 1 native TLS key per enumerable_thread_specific instance. The number of native TLS keys may be limited and can be fairly small.

enum ets_key_usage_type::ets_no_key

Enumeration parameter type used to select an implementation that consumes no native TLS keys. If no ets_key_usage_type parameter type is provided, ets_no_key is used by default.

enum ets_key_usage_type::ets_suspend_aware

The `oneapi::tbb::task::suspend` function can change the value of the enumerable_thread_specific object. To avoid this problem, use the ets_suspend_aware enumeration parameter type. The `local()` value can be the same for different threads, but no two distinct threads can access the same value simultaneously.

This section also describes class template `flatten2d`, which assists a common idiom where an enumerable_thread_specific represents a container partitioner across threads.

flattened2d

[tls.flattened2d]

The class template `flattened2d` is an adaptor that provides a flattened view of a container of containers.

```
// Defined in header <oneapi/tbb/enumerable_thread_specific.h>

namespace oneapi {
namespace tbb {

    template<typename Container>
    class flattened2d {
    public:
        // Basic types
        using size_type = /* implementation-defined */;
        using difference_type = /* implementation-defined */;
        using allocator_type = /* implementation-defined */;
        using value_type = /* implementation-defined */;
        using reference = /* implementation-defined */;
        using const_reference = /* implementation-defined */;
        using pointer = /* implementation-defined */;
        using const_pointer = /* implementation-defined */;

        using iterator = /* implementation-defined */;
        using const_iterator = /* implementation-defined */;

        explicit flattened2d( const Container& c );
    };
};
};
```

(continues on next page)

(continued from previous page)

```

    flattened2d( const Container& c,
                typename Container::const_iterator first,
                typename Container::const_iterator last );

    iterator begin();
    iterator end();
    const_iterator begin() const;
    const_iterator end() const;

    size_type size() const;
};

template <typename Container>
flattened2d<Container> flatten2d(const Container &c);

template <typename Container>
flattened2d<Container> flatten2d(
    const Container &c,
    const typename Container::const_iterator first,
    const typename Container::const_iterator last);

} // namespace tbb
} // namespace oneapi

```

Requirements:

- A Container type must meet the container requirements from the [container.requirements.general] ISO C++ section.

Iterating from `begin()` to `end()` visits all of the elements in the inner containers. The class template supports forward iterators only.

The utility function `flatten2d` creates a `flattened2d` object from a specified container.

Member functions

explicit **flattened2d**(const Container &c)

Constructs a `flattened2d` representing the sequence of elements in the inner containers contained by outer container `c`.

Safety: these operations must not be invoked concurrently on the same `flattened2d`.

flattened2d(const Container &c, typename Container::const_iterator first, typename Container::const_iterator last)

Constructs a `flattened2d` representing the sequence of elements in the inner containers in the half-open interval `[first, last)` of a container `c`.

Safety: these operations must not be invoked concurrently on the same `flattened2d`.

size_type **size**() const

Returns the sum of the sizes of the inner containers that are viewable in the `flattened2d`.

Safety: These operations may be invoked concurrently on the same `flattened2d`.

iterator **begin**()

Returns `iterator` pointing to the beginning of the set of local copies.

iterator **end()**

Returns `iterator` pointing to the end of the set of local copies.

`const_iterator` **begin()** const

Returns `const_iterator` pointing to the beginning of the set of local copies.

`const_iterator` **end()** const

Returns `const_iterator` pointing to the end of the set of local copies.

Non-member functions

template<typename **Container**>

`flattened2d<Container>` **flatten2d**(const *Container* &c, const typename *Container*::const_iterator b, const
typename *Container*::const_iterator e)

Constructs and returns a `flattened2d` object that provides iterators that traverse the elements in the containers within the half-open range [b, e) of a container c.

template<typename **Container**>

flattened2d(const *Container* &c)

Constructs and returns a `flattened2d` that provides iterators that traverse the elements in all of the containers within a container c.

9.3 oneTBB Auxiliary Interfaces

9.3.1 Memory Allocation

[memory_allocation]

This section describes classes and functions related to memory allocation.

Allocators

The oneAPI Threading Building Blocks (oneTBB) library implements several classes that meet the allocator requirements from the [allocator.requirements] ISO C++ Standard section.

tbb_allocator

[memory_allocation.tbb_allocator]

A `tbb_allocator` is a class template that models the allocator requirements from the [allocator.requirements] ISO C++ section.

The `tbb_allocator` allocates and frees memory via the oneTBB `malloc` library if it is available, otherwise, it reverts to using `std::malloc` and `std::free`.

```
// Defined in header <oneapi/tbb/tbb_allocator.h>
namespace oneapi {
namespace tbb {
    template<typename T> class tbb_allocator {
    public:
        using value_type = T;
    };
};
```

(continues on next page)

(continued from previous page)

```

using size_type = std::size_t;
using propagate_on_container_move_assignment = std::true_type;
using is_always_equal = std::true_type;

enum malloc_type {
    scalable,
    standard
};

tbb_allocator() = default;
template<typename U>
tbb_allocator(const tbb_allocator<U>&) noexcept;

T* allocate(size_type);
void deallocate(T*, size_type);

static malloc_type allocator_type();
};
} // namespace tbb
} // namespace oneapi

```

Member Functions

T*allocate(*size_type* n)

Allocates $n * \text{sizeof}(T)$ bytes. Returns a pointer to the allocated memory.

void **deallocate**(T *p, *size_type* n)

Deallocates memory pointed to by p. The behavior is undefined if the pointer p is not the result of the allocate(n) method. The behavior is undefined if the memory has been already deallocated.

static malloc_type **allocator_type**()

Returns the enumeration type `malloc_type::scalable` if the oneTBB malloc library is available, and `malloc_type::standard`, otherwise.

Non-member Functions

These functions provide comparison operations between two `tbb_allocator` instances.

```

template<typename T, typename U>
bool operator==(const tbb_allocator<T>&, const tbb_allocator<U>&) noexcept;

template<typename T, typename U>
bool operator!=(const tbb_allocator<T>&, const tbb_allocator<U>&) noexcept;

```

The namespace where these functions are defined is unspecified, as long as they may be used in respective binary operation expressions on `tbb_allocator` objects. For example, an implementation may define the classes and functions in the same unspecified internal namespace and define `oneapi::tbb::tbb_allocator` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

template<typename T, typename U>

bool **operator==**(const tbb_allocator<T>&, const tbb_allocator<U>&) noexcept

Returns **true**.

```
template<typename T, typename U>
bool operator!=(const tbb_allocator<T>&, const tbb_allocator<U>&) noexcept
    Returns false.
```

scalable_allocator

[memory_allocation.scalable_allocator]

A `scalable_allocator` is a class template that models the allocator requirements from the [allocator.requirements] ISO C++ section.

The `scalable_allocator` allocates and frees memory in a way that scales with the number of processors. Memory allocated by a `scalable_allocator` should be freed by a `scalable_allocator`, not by a `std::allocator`.

```
// Defined in header <oneapi/tbb/scalable_allocator.h>

namespace oneapi {
namespace tbb {
    template<typename T> class scalable_allocator {
    public:
        using value_type = T;
        using size_type = std::size_t;
        using propagate_on_container_move_assignment = std::true_type;
        using is_always_equal = std::true_type;

        scalable_allocator() = default;
        template<typename U>
        scalable_allocator(const scalable_allocator<U>&) noexcept;

        T* allocate(size_type);
        void deallocate(T*, size_type);
    };
} // namespace tbb
} // namespace oneapi
```

Caution: The `scalable_allocator` requires the memory allocator library. If the library is missing, calls to the `scalable_allocator` fail. In contrast to `scalable_allocator`, if the memory allocator library is not available, `tbb_allocator` falls back on `std::malloc` and `std::free`.

Member Functions

```
value_type *allocate(size_type n)
```

Allocates $n * \text{sizeof}(T)$ bytes of memory. Returns a pointer to the allocated memory.

```
void deallocate(value_type *p, size_type n)
```

Deallocates memory pointed to by `p`. The behavior is undefined if the pointer `p` is not the result of the `allocate(n)` method. The behavior is undefined if the memory has been already deallocated.

Non-member Functions

These functions provide comparison operations between two `scalable_allocator` instances.

```
namespace oneapi {
namespace tbb {
    template<typename T, typename U>
    bool operator==(const scalable_allocator<T>&,
                   const scalable_allocator<U>&) noexcept;

    template<typename T, typename U>
    bool operator!=(const scalable_allocator<T>&,
                   const scalable_allocator<U>&) noexcept;
} // namespace tbb
} // namespace oneapi
```

The namespace where these functions are defined is unspecified, as long as they may be used in respective binary operation expressions on `scalable_allocator` objects. For example, an implementation may define the classes and functions in the same unspecified internal namespace, and define `oneapi::tbb::scalable_allocator` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

```
template<typename T, typename U>
bool operator==(const scalable_allocator<T>&, const scalable_allocator<U>&) noexcept
    Returns true.
```

```
template<typename T, typename U>
bool operator!=(const scalable_allocator<T>&, const scalable_allocator<U>&) noexcept
    Returns false.
```

cache_aligned_allocator

[memory_allocation.cache_aligned_allocator]

A `cache_aligned_allocator` is a class template that models the allocator requirements from the [allocator.requirements] ISO C++ section.

The `cache_aligned_allocator` allocates memory on cache line boundaries, in order to avoid false sharing and potentially improve performance. False sharing is a situation when logically distinct items occupy the same cache line, which can hurt performance if multiple threads attempt to access the different items simultaneously. Even though the items are logically separate, the processor hardware may have to transfer the cache line between the processors as if they were sharing a location. The net result can be much more memory traffic than if the logically distinct items were on different cache lines.

However, this class is sometimes an inappropriate replacement for default allocator, because the benefit of allocating on a cache line comes at the price that `cache_aligned_allocator` implicitly adds pad memory. Therefore allocating many small objects with `cache_aligned_allocator` may increase memory usage.

```
// Defined in header <oneapi/tbb/cache_aligned_allocator.h>

namespace oneapi {
namespace tbb {
    template<typename T> class cache_aligned_allocator {
    public:
        using value_type = T;
        using size_type = std::size_t;
    };
};
```

(continues on next page)

(continued from previous page)

```

using propagate_on_container_move_assignment = std::true_type;
using is_always_equal = std::true_type;

cache_aligned_allocator() = default;
template<typename U>
cache_aligned_allocator(const cache_aligned_allocator<U>&) noexcept;

T* allocate(size_type);
void deallocate(T*, size_type);
size_type max_size() const noexcept;
};
} // namespace tbb
} // namespace oneapi

```

Member Functions

T*allocate(*size_type* n)

Returns a pointer to the allocated $n * \text{sizeof}(T)$ bytes of memory, aligned on a cache-line boundary. The allocation may include extra hidden padding.

void **deallocate**(T *p, *size_type* n)

Deallocates memory pointed to by p. Deallocation also deallocates any extra hidden padding. The behavior is undefined if the pointer p is not the result of the `allocate(n)` method. The behavior is undefined if the memory has been already deallocated.

size_type **max_size**() const noexcept

Returns the largest value n for which the call `allocate(n)` might succeed with cache alignment constraints.

Non-member Functions

These functions provide comparison operations between two `cache_aligned_allocator` instances.

```

template<typename T, typename U>
bool operator==(const cache_aligned_allocator<T>&,
               const cache_aligned_allocator<U>&) noexcept;

template<typename T, typename U>
bool operator!=(const cache_aligned_allocator<T>&,
               const cache_aligned_allocator<U>&) noexcept;

```

The namespace where these functions are defined is unspecified, as long as they may be used in respective binary operation expressions on `cache_aligned_allocator` objects. For example, an implementation may define the classes and functions in the same unspecified internal namespace, and define `oneapi::tbb::cache_aligned_allocator` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

template<typename T, typename U>

bool **operator==**(const cache_aligned_allocator<T>&, const cache_aligned_allocator<U>&) noexcept
Returns **true**.

template<typename T, typename U>

bool **operator!=**(const cache_aligned_allocator<T>&, const cache_aligned_allocator<U>&) noexcept
Returns **false**.

Memory Resources

Starting from C++17, the standard library provides a `std::pmr::polymorphic_allocator` class that allocates memory from a supplied memory resource (see the [mem.poly.allocator.class] ISO/IEC 14882:2017 section). Class `std::pmr::memory_resource` is an abstract interface for user-side implementation of different allocation strategies. For details, see the [mem.res.class] ISO/IEC 14882:2017 standard section.

oneTBB provides a set of `std::pmr::memory_resource` implementations.

cache_aligned_resource

[memory_allocation.cache_aligned_resource]

A `cache_aligned_resource` is a general-purpose memory resource class, which acts as a wrapper to another memory resource to ensure that all allocations are aligned on cache line boundaries to avoid false sharing.

See the *cache_aligned_allocator template class* section for more information about false sharing avoidance.

```
// Defined in header <oneapi/tbb/cache_aligned_allocator.h>

namespace oneapi {
namespace tbb {
    class cache_aligned_resource {
    public:
        cache_aligned_resource();
        explicit cache_aligned_resource( std::pmr::memory_resource* );

        std::pmr::memory_resource* upstream_resource() const;

    private:
        void* do_allocate(size_t n, size_t alignment) override;
        void do_deallocate(void* p, size_t n, size_t alignment) override;
        bool do_is_equal(const std::pmr::memory_resource& other) const noexcept override;
    };
} // namespace tbb
} // namespace oneapi
```

Member Functions

cache_aligned_resource()

Constructs a `cache_aligned_resource` over `std::pmr::get_default_resource()`.

explicit cache_aligned_resource(std::pmr::memory_resource *r)

Constructs a `cache_aligned_resource` over the memory resource `r`.

std::pmr::memory_resource *upstream_resource() const

Returns the pointer to the underlying memory resource.

void *do_allocate(size_t n, size_t alignment) override

Allocates `n` bytes of memory on a cache-line boundary, with alignment not less than requested. The allocation may include extra memory for padding. Returns pointer to the allocated memory.

void do_deallocate(void *p, size_t n, size_t alignment) override

Deallocates memory pointed to by `p` and any extra padding. Pointer `p` must be obtained with `do_allocate(n, alignment)`. The memory must not be deallocated beforehand.

bool **do_is_equal**(const std::pmr::memory_resource &other) const noexcept override
 Compares upstream memory resources of *this and other. If other is not a cache_aligned_resource, returns false.

scalable_memory_resource

[memory_allocation.scalable_memory_resource]

A oneapi::tbb::scalable_memory_resource() is a function that returns a memory resource for scalable memory allocation.

The scalable_memory_resource() function returns the pointer to the memory resource managed by the oneTBB scalable memory allocator. In particular, its allocate method uses scalable_aligned_malloc(), and deallocate uses scalable_free(). The memory resources returned by this function compare equal.

std::pmr::polymorphic_allocator instantiated with oneapi::tbb::scalable_memory_resource() behaves like oneapi::tbb::scalable_allocator.

```
// Defined in header <oneapi/tbb/scalable_allocator.h>
std::pmr::memory_resource* scalable_memory_resource();
```

Library Functions

C Interface to Scalable Allocator

[memory_allocation.scalable_alloc_c_interface]

Low-level interface for scalable memory allocation.

```
// Defined in header <oneapi/tbb/scalable_allocator.h>
extern "C" {
    // Scalable analogs of C memory allocator
    void* scalable_malloc( size_t size );
    void scalable_free( void* ptr );
    void* scalable_calloc( size_t nobj, size_t size );
    void* scalable_realloc( void* ptr, size_t size );

    // Analog of _msize/malloc_size/malloc_usable_size.
    size_t scalable_msize( void* ptr );

    // Scalable analog of posix_memalign
    int scalable_posix_memalign( void** memptr, size_t alignment, size_t size );

    // Aligned allocation
    void* scalable_aligned_malloc( size_t size, size_t alignment);
    void scalable_aligned_free( void* ptr );
    void* scalable_aligned_realloc( void* ptr, size_t size, size_t alignment );

    // Return values for scalable_allocation_* functions
    typedef enum {
        TBBMALLOC_OK,
```

(continues on next page)

(continued from previous page)

```

    TBBMALLOC_INVALID_PARAM,
    TBBMALLOC_UNSUPPORTED,
    TBBMALLOC_NO_MEMORY,
    TBBMALLOC_NO_EFFECT
} ScalableAllocationResult;

typedef enum {
    // To turn on/off the use of huge memory pages
    TBBMALLOC_USE_HUGE_PAGES,
    // To set a threshold for the allocator memory usage.
    // Exceeding it will forcefully clean internal memory buffers
    TBBMALLOC_SET_SOFT_HEAP_LIMIT,
    // Lower bound for the size (Bytes), that is interpreted as huge
    // and not released during regular cleanup operations
    TBBMALLOC_SET_HUGE_SIZE_THRESHOLD
} AllocationModeParam;

// Set allocator-specific allocation modes.
int scalable_allocation_mode(int param, intptr_t value);

typedef enum {
    // Clean internal allocator buffers for all threads.
    TBBMALLOC_CLEAN_ALL_BUFFERS,
    // Clean internal allocator buffer for current thread only.
    TBBMALLOC_CLEAN_THREAD_BUFFERS
} ScalableAllocationCmd;

// Call allocator-specific commands.
int scalable_allocation_command(int cmd, void *param);
}

```

These functions provide a C-level interface to the scalable allocator. With the exception of `scalable_allocation_mode` and `scalable_allocation_command`, each routine `scalable_x` behaves analogously to the library function `x`. The routines form the two families shown in the table below, “C Interface to Scalable Allocator”. Storage allocated by a `scalable_x` function in one family must be freed or resized by the `scalable_x` function in the same family, not by a C standard library function. Likewise, storage allocated by a C standard library function should not be freed or resized by a `scalable_x` function.

Table 5: C Interface to Scalable Allocator

Allocation Routine	Deallocation Routine	Analogous Library
<code>scalable_malloc</code>	<code>scalable_free</code>	C standard library
<code>scalable_calloc</code>		
<code>scalable_realloc</code>		POSIX*
<code>scalable_posix_memalign</code>		
<code>scalable_aligned_malloc</code>	<code>scalable_aligned_free</code>	Microsoft* C run-time library
<code>scalable_aligned_realloc</code>		

The following functions do not allocate or free memory but allow obtaining useful information or influencing behavior of the memory allocator.

`size_t` **scalable_msize**(void *ptr)

Returns: The usable size of the memory block pointed to by `ptr` if it was allocated by the scalable allocator.

Returns zero if *ptr* does not point to such a block.

int **scalable_allocation_mode**(int mode, intptr_t value)

Use this function to adjust behavior of the scalable memory allocator.

Returns: TBBMALLOC_OK if the operation succeeded, TBBMALLOC_INVALID_PARAM if mode is not one of the described below, or if value is not valid for the given mode. Other return values are possible, as described below.

scalable_allocation_mode Parameters: Parameter, Description

TBBMALLOC_USE_HUGE_PAGES

scalable_allocation_mode(TBBMALLOC_USE_HUGE_PAGES, 1) tells the allocator to use huge pages if enabled by the operating system. scalable_allocation_mode(TBBMALLOC_USE_HUGE_PAGES, 0) disables it. Setting TBB_MALLOC_USE_HUGE_PAGES environment variable to 1 has the same effect as scalable_allocation_mode(TBBMALLOC_USE_HUGE_PAGES, 1). The mode set with scalable_allocation_mode() takes priority over the environment variable.

May return: TBBMALLOC_NO_EFFECT if huge pages are not supported on the platform.

For now, this allocation mode is only supported for Linux* OS. It works with both explicitly configured and transparent huge pages. For information about enabling and configuring huge pages, refer to OS documentation or ask your system administrator.

TBBMALLOC_SET_SOFT_HEAP_LIMIT

scalable_allocation_mode(TBBMALLOC_SET_SOFT_HEAP_LIMIT, size) sets a threshold of size bytes on the amount of memory the allocator takes from OS. Exceeding the threshold urges the allocator to release memory from its internal buffers; however it does not prevent from requesting more memory if needed.

TBBMALLOC_SET_HUGE_SIZE_THRESHOLD

scalable_allocation_mode(TBBMALLOC_SET_HUGE_SIZE_THRESHOLD, size) sets a lower bound threshold (with no upper limit) of size bytes. Any object bigger than this threshold becomes huge and does not participate in internal periodic cleanup logic. However, it does not affect the logic of the TBBMALLOC_SET_SOFT_HEAP_LIMIT mode as well as the TBBMALLOC_CLEAN_ALL_BUFFERS operation.

Setting TBB_MALLOC_SET_HUGE_SIZE_THRESHOLD environment variable to the size value has the same effect, but is limited to the LONG_MAX value. The mode set with scalable_allocation_mode takes priority over the environment variable.

int **scalable_allocation_command**(int cmd, void *reserved)

This function may be used to command the scalable memory allocator to perform an action specified by the first parameter. The second parameter is reserved and must be set to 0.

Returns: TBBMALLOC_OK if the operation succeeded, TBBMALLOC_INVALID_PARAM if cmd is not one of the described below, or if reserved is not equal to 0.

scalable_allocation_command Parameters: Parameter, Description

TBBMALLOC_CLEAN_ALL_BUFFERS

scalable_allocation_command(TBBMALLOC_CLEAN_ALL_BUFFERS, 0) cleans internal memory buffers of the allocator, and possibly reduces memory footprint. It may result in increased time for subsequent memory allocation requests. The command is not designed for frequent use, and careful evaluation of the performance impact is recommended.

May return: TBBMALLOC_NO_EFFECT if no buffers were released.

Note: It is not guaranteed that the call will release all unused memory.

TBBMALLOC_CLEAN_THREAD_BUFFERS

`scalable_allocation_command(TBBMALLOC_CLEAN_THREAD_BUFFERS, 0)` cleans internal memory buffers, but only for the calling thread.

May return: `TBBMALLOC_NO_EFFECT` if no buffers were released.

9.3.2 Mutual Exclusion

[mutex]

The library provides a set of mutual exclusion primitives to simplify writing race-free code. A mutex object facilitates protection against data races and provides safe synchronization of data between threads.

Mutex Classes

mutex

[mutex.mutex]

A mutex is a class that models *Mutex requirement* using an adaptive approach, it guarantees that the thread that cannot acquire the lock spins before blocking. The `mutex` class satisfies all of the mutex requirements described in the [thread.mutex.requirements] section of the ISO C++ standard. The `mutex` class is not fair or recursive.

```
// Defined in header <oneapi/tbb/mutex.h>

namespace oneapi {
    namespace tbb {
        class mutex {
        public:
            mutex() noexcept;
            ~mutex();

            mutex(const mutex&) = delete;
            mutex& operator=(const mutex&) = delete;

            class scoped_lock;

            void lock();
            bool try_lock();
            void unlock();

            static constexpr bool is_rw_mutex = false;
            static constexpr bool is_recursive_mutex = false;
            static constexpr bool is_fair_mutex = false;
        };
    }
}
```

Member classes

class `scoped_lock`

The corresponding `scoped_lock` class. See *Mutex requirement*.

Member functions

`mutex()`

Constructs a `mutex` with the unlocked state.

`~mutex()`

Destroys an unlocked `mutex`.

void `lock()`

Acquires a lock. It uses an adaptive logic for waiting, thus it is blocked after a certain time of busy waiting.

bool `try_lock()`

Tries to acquire a lock (non-blocking). Returns **true** if succeeded; **false** otherwise.

void `unlock()`

Releases the lock held by a current thread.

`rw_mutex`

[`mutex.rw_mutex`]

A `rw_mutex` is a class that models *ReaderWriterMutex requirement* using an adaptive approach, it guarantees that the thread that cannot acquire the lock spins before blocking. The `rw_mutex` class satisfies all of the shared mutex requirements described in the [thread.sharedmutex.requirements] section of the ISO C++ standard. The `rw_mutex` class is an unfair reader-writer lock with a writer preference.

```
// Defined in header <oneapi/tbb/rw_mutex.h>

namespace oneapi {
    namespace tbb {
        class rw_mutex {
        public:
            rw_mutex() noexcept;
            ~rw_mutex();

            rw_mutex(const rw_mutex&) = delete;
            rw_mutex& operator=(const rw_mutex&) = delete;

            class scoped_lock;

            // exclusive ownership
```

(continues on next page)

(continued from previous page)

```

    void lock();
    bool try_lock();
    void unlock();

    // shared ownership
    void lock_shared();
    bool try_lock_shared();
    void unlock_shared();

    static constexpr bool is_rw_mutex = true;
    static constexpr bool is_recursive_mutex = false;
    static constexpr bool is_fair_mutex = false;
};
}
}

```

Member classes

class `scoped_lock`

The corresponding scoped-lock class. See *ReaderWriterMutex requirement*.

Member functions

`rw_mutex()`

Constructs an unlocked `rw_mutex`.

`~rw_mutex()`

Destroys an unlocked `rw_mutex`.

void `lock()`

Acquires a lock. It uses an adaptive logic for waiting, thus it is blocked after a certain time of busy waiting.

bool `try_lock()`

Tries to acquire a lock (non-blocking) on write. Returns **true** if succeeded; **false** otherwise.

void `unlock()`

Releases the write lock held by the current thread.

void `lock_shared()`

Acquires a lock on read. It uses an adaptive logic for waiting, thus it is blocked after a certain time of busy waiting.

bool **try_lock_shared()**

Tries to acquire the lock (non-blocking) on read. Returns **true** if succeeded; **false** otherwise.

void **unlock_shared()**

Releases the read lock held by the current thread.

spin_mutex

[mutex.spin_mutex]

A `spin_mutex` is a class that models the *Mutex requirement* using a spin lock. The `spin_mutex` class satisfies all requirements of mutex type from the [thread.mutex.requirements] ISO C++ section. The `spin_mutex` class is not fair or recursive.

```
// Defined in header <oneapi/tbb/spin_mutex.h>

namespace oneapi {
namespace tbb {
    class spin_mutex {
    public:
        spin_mutex() noexcept;
        ~spin_mutex();

        spin_mutex(const spin_mutex&) = delete;
        spin_mutex& operator=(const spin_mutex&) = delete;

        class scoped_lock;

        void lock();
        bool try_lock();
        void unlock();

        static constexpr bool is_rw_mutex = false;
        static constexpr bool is_recursive_mutex = false;
        static constexpr bool is_fair_mutex = false;
    };
} // namespace tbb
} // namespace oneapi
```

Member classes

class **scoped_lock**

Corresponding `scoped_lock` class. See the *Mutex requirement*.

Member functions

`spin_mutex()`

Constructs `spin_mutex` with unlocked state.

`~spin_mutex()`

Destroys an unlocked `spin_mutex`.

`void lock()`

Acquires a lock. Spins if the lock is taken.

`bool try_lock()`

Attempts to acquire a lock (non-blocking). Returns **true** if lock is acquired; **false**, otherwise.

`void unlock()`

Releases a lock held by a current thread.

`spin_rw_mutex`

[`mutex.spin_rw_mutex`]

A `spin_rw_mutex` is a class that models the *ReaderWriterMutex requirement* and satisfies all requirements of shared mutex type from the [thread.sharedmutex.requirements] ISO C++ section.

The `spin_rw_mutex` class is unfair spinning reader-writer lock with backoff and writer-preference.

```
// Defined in header <oneapi/tbb/spin_rw_mutex.h>

namespace oneapi {
namespace tbb {
class spin_rw_mutex {
public:
    spin_rw_mutex() noexcept;
    ~spin_rw_mutex();

    spin_rw_mutex(const spin_rw_mutex&) = delete;
    spin_rw_mutex& operator=(const spin_rw_mutex&) = delete;

    class scoped_lock;

    // exclusive ownership
    void lock();
    bool try_lock();
    void unlock();

    // shared ownership
    void lock_shared();
    bool try_lock_shared();
    void unlock_shared();

    static constexpr bool is_rw_mutex = true;
    static constexpr bool is_recursive_mutex = false;
    static constexpr bool is_fair_mutex = false;
};
```

(continues on next page)

(continued from previous page)

```

} // namespace tbb
} // namespace oneapi

```

Member classes

class **scoped_lock**

Corresponding scoped-lock class. See the *ReaderWriterMutex requirement*.

Member functions

spin_rw_mutex()

Constructs unlocked `spin_rw_mutex`.

~spin_rw_mutex()

Destroys unlocked `spin_rw_mutex`.

void **lock()**

Acquires a lock. Spins if the lock is taken.

bool **try_lock()**

Attempts to acquire a lock (non-blocking) on write. Returns true if the lock is acquired on write; false otherwise.

void **unlock()**

Releases a write lock, held by the current thread.

void **lock_shared()**

Acquires a lock on read. Spins if the lock is taken on write already.

bool **try_lock_shared()**

Attempts to acquire the lock (non-blocking) on read. Returns true if the lock is acquired on read; false, otherwise.

void **unlock_shared()**

Releases a read lock held by the current thread.

speculative_spin_mutex

[`mutex.speculative_spin_mutex`]

A `speculative_spin_mutex` is a class that models the *Mutex requirement* using a spin lock, and for processors that support hardware transactional memory (such as Intel® Transactional Synchronization Extensions (Intel® TSX)) may be implemented in a way that allows non-contending changes to the protected data to proceed in parallel.

The `speculative_spin_mutex` is not fair and not recursive. The `speculative_spin_mutex` is like a `spin_mutex`, but it may provide better throughput than non-speculative mutexes when the following conditions are met:

- Running on a processor that supports hardware transactional memory.
- Multiple threads can concurrently execute the critical section(s) protected by the mutex, mostly without conflicting.

Otherwise, it performs like a `spin_mutex`, possibly with worse throughput.

```
// Defined in header <oneapi/tbb/spin_mutex.h>

namespace oneapi {
namespace tbb {
    class speculative_spin_mutex {
    public:
        speculative_spin_mutex() noexcept;
        ~speculative_spin_mutex();

        speculative_spin_mutex(const speculative_spin_mutex&) = delete;
        speculative_spin_mutex& operator=(const speculative_spin_mutex&) = delete;

        class scoped_lock;

        static constexpr bool is_rw_mutex = false;
        static constexpr bool is_recursive_mutex = false;
        static constexpr bool is_fair_mutex = false;
    };
} // namespace tbb
} // namespace oneapi
```

Member classes

class `scoped_lock`

Corresponding `scoped_lock` class. See the [Mutex requirement](#).

Member functions

`speculative_spin_mutex()`

Constructs `speculative_spin_mutex` with unlocked state.

`~speculative_spin_mutex()`

Destroys an unlocked `speculative_spin_mutex`.

`speculative_spin_rw_mutex`

[`mutex.speculative_spin_rw_mutex`]

A `speculative_spin_rw_mutex` is a class that models the [ReaderWriterMutex requirement](#), and for processors that support hardware transactional memory (such as Intel® Transactional Synchronization Extensions (Intel® TSX)) may be implemented in a way that allows non-contending changes to the protected data to proceed in parallel.

The `speculative_spin_rw_mutex` class is not fair and not recursive. The `speculative_spin_rw_mutex` class is like a `spin_rw_mutex`, but it may provide better throughput than non-speculative mutexes when the following conditions are met:

- Running on a processor that supports hardware transactional memory.
- Multiple threads can concurrently execute the critical section(s) protected by the mutex, mostly without conflicting.

Otherwise, it performs like a `spin_rw_mutex`, possibly with worse throughput.

For processors that support hardware transactional memory, `speculative_spin_rw_mutex` may be implemented in a way that

- speculative readers and writers do not block each other
- a non-speculative reader blocks writers but allows speculative readers
- a non-speculative writer blocks all readers and writers

```
// Defined in header <oneapi/tbb/spin_rw_mutex.h>

namespace oneapi {
namespace tbb {
    class speculative_spin_rw_mutex {
    public:
        speculative_spin_rw_mutex() noexcept;
        ~speculative_spin_rw_mutex();

        speculative_spin_rw_mutex(const speculative_spin_rw_mutex&) = delete;
        speculative_spin_rw_mutex& operator=(const speculative_spin_rw_mutex&) = delete;

        class scoped_lock;

        static constexpr bool is_rw_mutex = true;
        static constexpr bool is_recursive_mutex = false;
        static constexpr bool is_fair_mutex = false;
    };
} // namespace tbb
} // namespace oneapi
```

Member classes

class `scoped_lock`

Corresponding `scoped_lock` class. See the *ReaderWriterMutex requirement*.

Member functions

`speculative_spin_rw_mutex()`

Constructs `speculative_spin_rw_mutex` with unlocked state.

`~speculative_spin_rw_mutex()`

Destroys an unlocked `speculative_spin_rw_mutex`.

queuing_mutex

[`mutex.queuing_mutex`]

A `queuing_mutex` is a class that models the *Mutex requirement*. The `queuing_mutex` is not recursive. The `queuing_mutex` is fair, threads acquire a lock on a mutex in the order that they request it.

```
// Defined in header <oneapi/tbb/queuing_mutex.h>

namespace oneapi {
```

(continues on next page)

(continued from previous page)

```

namespace tbb {
    class queuing_mutex {
    public:
        queuing_mutex() noexcept;
        ~queuing_mutex();

        queuing_mutex(const queuing_mutex&) = delete;
        queuing_mutex& operator=(const queuing_mutex&) = delete;

        class scoped_lock;

        static constexpr bool is_rw_mutex = false;
        static constexpr bool is_recursive_mutex = false;
        static constexpr bool is_fair_mutex = true;
    };
} // namespace tbb
} // namespace oneapi

```

Member classes

class `scoped_lock`

Corresponding `scoped_lock` class. See the *Mutex requirement*.

Member functions

`queuing_mutex()`

Constructs unlocked `queuing_mutex`.

`~queuing_mutex()`

Destroys unlocked `queuing_mutex`.

`queuing_rw_mutex`

[`mutex.queuing_rw_mutex`]

A `queuing_rw_mutex` is a class that models the *ReaderWriterMutex requirement* concept. The `queuing_rw_mutex` is not recursive. The `queuing_rw_mutex` is fair, threads acquire a lock on a mutex in the order that they request it.

```

// Defined in header <oneapi/tbb/queuing_rw_mutex.h>

namespace oneapi {
namespace tbb {
    class queuing_rw_mutex {
    public:
        queuing_rw_mutex() noexcept;
        ~queuing_rw_mutex();

        queuing_rw_mutex(const queuing_rw_mutex&) = delete;
        queuing_rw_mutex& operator=(const queuing_rw_mutex&) = delete;
    };
}
}

```

(continues on next page)

(continued from previous page)

```

class scoped_lock;

static constexpr bool is_rw_mutex = true;
static constexpr bool is_recursive_mutex = false;
static constexpr bool is_fair_mutex = true;
};
} // namespace tbb
} // namespace oneapi

```

Member classes

class `scoped_lock`

Corresponding `scoped_lock` class. See the *ReaderWriterMutex requirement*.

Member functions

`queuing_rw_mutex()`

Constructs unlocked `queuing_rw_mutex`.

`~queuing_rw_mutex()`

Destroys unlocked `queuing_rw_mutex`.

`null_mutex`

[`mutex.null_mutex`]

A `null_mutex` is a class that models the *Mutex requirement* concept syntactically, but does nothing. It is useful for instantiating a template that expects a `Mutex`, but no mutual exclusion is actually needed for that instance.

```

// Defined in header <oneapi/tbb/null_mutex.h>

namespace oneapi {
namespace tbb {
class null_mutex {
public:
constexpr null_mutex() noexcept;
~null_mutex();

null_mutex(const null_mutex&) = delete;
null_mutex& operator=(const null_mutex&) = delete;

class scoped_lock;

void lock();
bool try_lock();
void unlock();

static constexpr bool is_rw_mutex = false;
static constexpr bool is_recursive_mutex = true;
static constexpr bool is_fair_mutex = true;
};
} // namespace tbb
} // namespace oneapi

```

(continues on next page)

(continued from previous page)

```
};
} // namespace tbb
} // namespace oneapi
```

Member classes

class **scoped_lock**

Corresponding `scoped_lock` class. See the *Mutex requirement*.

Member functions

null_mutex()

Constructs unlocked mutex.

~null_mutex()

Destroys unlocked mutex.

void **lock()**

Acquires lock.

bool **try_lock()**

Tries acquiring lock (non-blocking).

void **unlock()**

Releases the lock.

null_rw_mutex

[**mutex.null_rw_mutex**]

A `null_rw_mutex` is a class that models the *ReaderWriterMutex requirement* syntactically, but does nothing. The `null_rw_mutex` class also satisfies all syntactic requirements of shared mutex type from the [thread.sharedmutex.requirements] ISO C++ section, but does nothing. It is useful for instantiating a template that expects a `ReaderWriterMutex`, but no mutual exclusion is actually needed for that instance.

```
// Defined in header <oneapi/tbb/null_rw_mutex.h>

namespace oneapi {
namespace tbb {
class null_rw_mutex {
public:
    constexpr null_rw_mutex() noexcept;
    ~null_rw_mutex();

    null_rw_mutex(const null_rw_mutex&) = delete;
    null_rw_mutex& operator=(const null_rw_mutex&) = delete;

    class scoped_lock;

    void lock();
    bool try_lock();
```

(continues on next page)

(continued from previous page)

```

    void unlock();

    void lock_shared();
    bool try_lock_shared();
    void unlock_shared();

    static constexpr bool is_rw_mutex = true;
    static constexpr bool is_recursive_mutex = true;
    static constexpr bool is_fair_mutex = true;
};
} // namespace tbb
} // namespace oneapi

```

Member classes

class `scoped_lock`

Corresponding `scoped_lock` class. See the *ReaderWriterMutex requirement*.

Member functions

`null_rw_mutex()`

Constructs unlocked mutex.

`~null_rw_mutex()`

Destroys unlocked mutex.

void `lock()`

Acquires a lock.

bool `try_lock()`

Attempts to acquire a lock (non-blocking) on write. Returns **true**.

void `unlock()`

Releases a write lock held by the current thread.

void `lock_shared()`

Acquires a lock on read.

bool `try_lock_shared()`

Attempts to acquire the lock (non-blocking) on read. Returns **true**.

void `unlock_shared()`

Releases a read lock held by the current thread.

9.3.3 Timing

[timing]

Parallel programming is about speeding up *wall clock* time, which is the real time that it takes a program or function to run. The library provides API to simplify timing within an application.

Syntax

```
// Declared in tick_count.h

class tick_count;

class tick_count::interval_t;
```

Classes

tick_count class

[timing.tick_count]

A `tick_count` is an absolute wall clock timestamp. Two `tick_count` objects can be subtracted to compute wall clock duration `tick_count::interval_t`, which can be converted to seconds.

```
namespace oneapi {
namespace tbb {

    class tick_count {
    public:
        class interval_t;
        tick_count();
        tick_count( const tick_count& );
        ~tick_count();
        tick_count& operator=( const tick_count& );
        static tick_count now();
        static double resolution();
    };

} // namespace tbb
} // namespace oneapi
```

`tick_count()` Constructs `tick_count` with an unspecified wall clock timestamp.

`tick_count(const tick_count&)` Constructs `tick_count` with the timestamp of the given `tick_count`.

`~tick_count()` Destructor.

`tick_count& operator=(const tick_count&)` Assigns the timestamp of one `tick_count` to another.

`static tick_count now()` Returns a `tick_count` object that represents the current wall clock timestamp.

`static double resolution()` Returns the resolution of the clock used by `tick_count`, in seconds.

tick_count::interval_t class**[timing.tick_count.interval_t]**A `tick_count::interval_t` represents wall clock duration.

```

namespace oneapi {
namespace tbb {

    class tick_count::interval_t {
    public:
        interval_t();
        explicit interval_t( double );
        ~interval_t();
        interval_t& operator=( const interval_t& );
        interval_t& operator+=( const interval_t& );
        interval_t& operator-=( const interval_t& );
        double seconds() const;
    };

} // namespace tbb
} // namespace oneapi

```

interval_t() Constructs `interval_t` representing zero time duration.**explicit interval_t(double)** Constructs `interval_t` representing the specified number of seconds.**~interval_t()** Destructor.**interval_t& operator=(const interval_t&)** Assigns the wall clock duration of one `interval_t` to another.**interval_t& operator+=(const interval_t&)** Increases the duration to the given `interval_t`, and returns `*this`.**interval_t& operator-=(const interval_t&)** Decreases the duration to the given `interval_t`, and returns `*this`.**double seconds() const** Returns the duration measured in seconds.**Non-member functions****[timing.tick_count.nonmember]**

These functions provide arithmetic binary operations with wall clock timestamps and durations.

```

oneapi::tbb::tick_count::interval_t operator-( const oneapi::tbb::tick_count&, const_
↪ oneapi::tbb::tick_count& );
oneapi::tbb::tick_count::interval_t operator+( const oneapi::tbb::tick_count::interval_t&
↪, const oneapi::tbb::tick_count::interval_t& );
oneapi::tbb::tick_count::interval_t operator-( const oneapi::tbb::tick_count::interval_t&
↪, const oneapi::tbb::tick_count::interval_t& );

```

The namespace where these functions are defined is unspecified as long as they may be used in respective binary operation expressions on `tick_count` and `tick_count::interval_t` objects. For example, an implementation may define the classes and functions in the same unspecified internal namespace, and define `oneapi::tbb::tick_count` as a type alias for which the non-member functions are reachable only via argument-dependent lookup.

oneapi::tbb::tick_count::interval_t operator-(const oneapi::tbb::tick_count&, const oneapi::tbb::tick_count&)
Returns interval_t representing the duration between two given wall clock timestamps.

oneapi::tbb::tick_count::interval_t operator+(const oneapi::tbb::tick_count::interval_t&, const oneapi::tbb::tick_count::interval_t&)
Returns interval_t representing the sum of two given intervals.

oneapi::tbb::tick_count::interval_t operator-(const oneapi::tbb::tick_count::interval_t&, const oneapi::tbb::tick_count::interval_t&)
Returns interval_t representing the difference of two given intervals.

9.3.4 info Namespace

[info_namespace]

Interfaces to query information about execution environment.

```
// Declared in header <oneapi/tbb/info.h>

namespace oneapi {
namespace tbb {
    using numa_node_id = /*implementation-defined*/;
    using core_type_id = /*implementation-defined*/;

    namespace info {
        std::vector<numa_node_id> numa_nodes();
        std::vector<core_type_id> core_types();

        int default_concurrency(task_arena::constraints c);
        int default_concurrency(numa_node_id id = oneapi::tbb::task_arena::automatic);
    }
} // namespace tbb
} // namespace oneapi
```

Types

numa_node_id - Represents NUMA node identifier.

Functions

std::vector<numa_node_id> **numa_nodes()**
Returns the vector of integral indexes that indicate available NUMA nodes.

Note: If error occurs during system topology parsing, returns vector containing single element that equals to task_arena::automatic.

std::vector<core_type_id> **core_types()**
Returns the vector of integral indexes that indicate available core types. The indexes are sorted from the least performant to the most performant core type.

Note: If error occurs during system topology parsing, returns vector containing single element that equals to task_arena::automatic.

int **default_concurrency**(*task_arena::constraints c*)
Returns concurrency level for the given constraints.

int **default_concurrency**(*numa_node_id id = oneapi::tbb::task_arena::automatic*)
Returns concurrency level of the given NUMA node. If argument is not specified, returns default concurrency level for current library configuration.

9.4 oneTBB Deprecated Interfaces

9.4.1 *task_arena::attach*

[*deprecated.task_arena_attach_tag*]

Caution: Deprecated in oneTBB Specification 1.1.

A set of methods for constructing a *task_arena* with *attach*.

```
// Defined in header <oneapi/tbb/task_arena.h>

namespace oneapi {
    namespace tbb {

        class task_arena {
        public:
            // ...
            struct attach {};

            explicit task_arena(task_arena::attach);
            void initialize(task_arena::attach);
            // ...
        };

    } // namespace tbb
} // namespace oneapi
```

Member types and constants

struct **attach**

A tag for constructing a `task_arena` with `attach`.

Member functions

explicit **task_arena**(*task_arena::attach*)

Creates an instance of `task_arena` that is connected to the internal task arena representation currently used by the calling thread. If no such arena exists yet, creates a `task_arena` with default parameters.

Note: Unlike other `task_arena` constructors, this one automatically initializes the new `task_arena` when connecting to an already existing arena.

void **initialize**(*task_arena::attach*)

If an internal task arena representation currently used by the calling thread, the method ignores arena parameters and connects `task_arena` to that internal task arena representation. The method has no effect when called for an already initialized `task_arena`.

See also:

- *attach*

ONEVPL

The oneAPI Video Processing Library (oneVPL) is a programming interface for video decoding, encoding, and processing to build portable media pipelines on CPUs, GPUs, and other accelerators. It provides device discovery and selection in media centric and video analytics workloads and API primitives for zero-copy buffer sharing. oneVPL is backwards and cross-architecture compatible to ensure optimal execution on current and next generation hardware without source code changes.

oneVPL Specification Version

This document contains oneVPL specification version of 2.8.0.

Latest published version of oneVPL specification: <https://spec.oneapi.com/onevpl/latest/index.html>.

10.1 oneVPL for Intel® Media Software Development Kit Users

oneVPL is source compatible with Intel® Media Software Development Kit. Applications can use Intel® Media Software Development Kit to target older hardware and oneVPL to target everything else. Some obsolete features of Intel® Media Software Development Kit have been omitted from oneVPL. Hereinafter the term “Legacy” will be used to describe a behavior when oneVPL is called by Intel® Media Software Development Kit applications.

10.1.1 oneVPL Ease of Use Enhancements

oneVPL provides improved ease of use compared to Intel® Media Software Development Kit. Ease of use enhancements include the following:

- Smart dispatcher with discovery of implementation capabilities. See *oneVPL Session* for more details.
- Simplified decoder initialization. See *Decoding Procedures* for more details.
- New memory management and components (session) interoperability. See *Internal Memory Management* and *Decoding Procedures* for more details.

10.1.2 New APIs in oneVPL

oneVPL introduces new functions that are not available in Intel® Media Software Development Kit.

New oneVPL dispatcher functions:

- *MFXLoad()*
- *MFXUnload()*
- *MFXCreateConfig()*
- *MFXSetConfigFilterProperty()*
- *MFXEnumImplementations()*
- *MFXCreateSession()*
- *MFXDispReleaseImplDescription()*

New oneVPL memory management functions:

- *MFXMemory_GetSurfaceForVPP()*
- *MFXMemory_GetSurfaceForVPPOut()*
- *MFXMemory_GetSurfaceForEncode()*
- *MFXMemory_GetSurfaceForDecode()*

New oneVPL implementation capabilities retrieval functions:

- *MFXQueryImplsDescription()*
- *MFXReleaseImplDescription()*

New oneVPL session initialization:

- *MFXInitialize()*

10.1.3 Intel® Media Software Development Kit Feature Removals

The following Intel® Media Software Development Kit features are considered obsolete and are not included in oneVPL:

- **Audio support.** oneVPL is intended for video processing. Audio APIs that duplicate functionality from other audio libraries such as [Sound Open Firmware](#) have been removed.
- **ENC and PAK interfaces.** Part of the Flexible Encode Infrastructure (FEI) and plugin interfaces which provide additional control over the encoding process for AVC and HEVC encoders. This feature was removed because it is not widely used by customers.
- **User plugins architecture.** oneVPL enables robust video acceleration through API implementations of many different video processing frameworks. Support of a Intel® Media Software Development Kit user plugin framework is obsolete. Intel® Media Software Development Kit RAW acceleration (Camera API) which is implemented as plugin is also obsolete, oneVPL enables RAW acceleration (Camera API) through oneVPL runtime such as oneVPL GPU runtime.
- **External buffer memory management.** A set of callback functions to replace internal memory allocation is obsolete.
- **Video Processing extended runtime functionality.** Video processing function `MFXVideoVPP_RunFrameVPPAsyncEx` is used for plugins only and is obsolete.
- **External threading.** The new threading model makes the `MFXDoWork` function obsolete.

- **Multi-frame encode.** A set of external buffers to combine several frames into one encoding call. This feature was removed because it is device specific and not commonly used.
- **Surface Type Neutral Transcoding.** Opaque memory support is removed and replaced with internal memory allocation concept.
- **Raw Acceleration.** Intel® Media Software Development Kit RAW acceleration (Camera API) which is implemented as plugin is obsolete, replaced by oneVPL and oneVPL runtime implementation. OneVPL reused most of Intel® Media Software Development Kit Camera API, but oneVPL camera API is not backward compatible with Intel® Media Software Development Kit camera API due to obsolete plugin mechanism in oneVPL and a few difference between oneVPL and Intel® Media Software Development Kit. The major difference between oneVPL and Intel® Media Software Development Kit are listed: 1) mfxCamGammaParam and mfxExtCamGammaCorrection are removed in oneVPL; 2) Added reserved bytes in mfxExtCamHotPixelRemoval, mfxCamVignetteCorrectionParam and mfxCamVignetteCorrectionElement for future extension; 3) Changed CCM from mfxF64 to mfxF32 in mfxExtCamColorCorrection3x3 and added more reserved bytes.

10.1.4 Intel® Media Software Development Kit API Removals

The following Intel® Media Software Development Kit functions are not included in oneVPL:

- **Audio related functions**
 - MFXAudioCORE_SyncOperation()
 - MFXAudioDECODE_Close()
 - MFXAudioDECODE_DecodeFrameAsync()
 - MFXAudioDECODE_DecodeHeader()
 - MFXAudioDECODE_GetAudioParam()
 - MFXAudioDECODE_Init()
 - MFXAudioDECODE_Query()
 - MFXAudioDECODE_QueryIOSize()
 - MFXAudioDECODE_Reset()
 - MFXAudioENCODE_Close()
 - MFXAudioENCODE_EncodeFrameAsync()
 - MFXAudioENCODE_GetAudioParam()
 - MFXAudioENCODE_Init()
 - MFXAudioENCODE_Query()
 - MFXAudioENCODE_QueryIOSize()
 - MFXAudioENCODE_Reset()
- **Flexible encode infrastructure functions**
 - MFXVideoENC_Close()
 - MFXVideoENC_GetVideoParam()
 - MFXVideoENC_Init()
 - MFXVideoENC_ProcessFrameAsync()
 - MFXVideoENC_Query()

- MFXVideoENC_QueryIOSurf()
- MFXVideoENC_Reset()
- MFXVideoPAK_Close()
- MFXVideoPAK_GetVideoParam()
- MFXVideoPAK_Init()
- MFXVideoPAK_ProcessFrameAsync()
- MFXVideoPAK_Query()
- MFXVideoPAK_QueryIOSurf()
- MFXVideoPAK_Reset()

- **User plugin functions**

- MFXAudioUSER_ProcessFrameAsync()
- MFXAudioUSER_Register()
- MFXAudioUSER_Unregister()
- MFXVideoUSER_GetPlugin()
- MFXVideoUSER_ProcessFrameAsync()
- MFXVideoUSER_Register()
- MFXVideoUSER_Unregister()
- MFXVideoUSER_Load()
- MFXVideoUSER_LoadByPath()
- MFXVideoUSER_UnLoad()
- MFXDoWork()

- **Memory functions**

- MFXVideoCORE_SetBufferAllocator()

- **Video processing functions**

- MFXVideoVPP_RunFrameVPPAsyncEx()

- **Memory type and IOPattern enumerations**

- MFX_IOPATTERN_IN_OPAQUE_MEMORY
- MFX_IOPATTERN_OUT_OPAQUE_MEMORY
- MFX_MEMTYPE_OPAQUE_FRAME

Important: Corresponding extension buffers are also removed.

The following behaviors occur when attempting to use a Intel® Media Software Development Kit API that is not supported by oneVPL:

- Code compiled with the oneVPL API headers will generate a compile and/or link error when attempting to use a removed API.
- Code previously compiled with Intel® Media Software Development Kit and executed using a oneVPL runtime will generate an *MFX_ERR_NOT_IMPLEMENTED* error when calling a removed function.

10.1.5 Intel® Media Software Development Kit Legacy API

oneVPL contains following header files from Intel® Media Software Development Kit included for the simplification of existing applications migration to oneVPL:

- mfxvideo++.h

Important: Intel® Media Software Development Kit obsolete API removed from those header files. Code compiled with the oneVPL API headers will generate a compile and/or link error when attempting to use a removed API.

10.2 Architecture

oneVPL functions fall into the following categories:

DECODE Functions that decode compressed video streams into raw video frames

ENCODE Functions that encode raw video frames into compressed bitstreams

VPP Functions that perform video processing on raw video frames

DECODE_VPP Functions that perform combined operations of decoding and video processing

CORE Auxiliary functions for synchronization

Misc Global auxiliary functions

With the exception of the global auxiliary functions, oneVPL functions are named after their functioning domain and category. oneVPL exposes video domain functions.

MFXVideoDECODE_DecodeFrameAsync

Prefix	Domain	Class	Name
--------	--------	-------	------

Fig. 1: oneVPL function name notation

Applications use oneVPL functions by linking with the oneVPL dispatcher library.

The dispatcher library identifies the hardware acceleration device on the running platform, determines the most suitable platform library for the identified hardware acceleration, and then redirects function calls accordingly.

10.2.1 Video Decoding

The *DECODE* class of functions take a compressed bitstream as input and converts it to raw frames as output.

DECODE processes only pure or elementary video streams with the exception of AV1/VP9/VP8 decoders, which accept the IVF format. The library can process bitstreams that reside in an IVF container but cannot process bitstreams that reside in any other container format, such as MP4 or MPEG.

The application must first demultiplex the bitstreams. Demultiplexing extracts pure video streams out of the container format. The application can provide the input bitstream as one complete frame of data, a partial frame (less than one complete frame), or as multiple frames. If only a partial frame is provided, DECODE internally constructs one frame of data before decoding it.

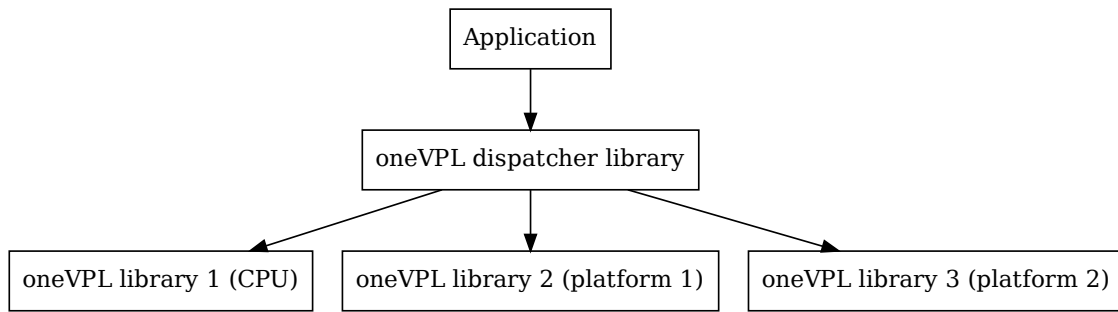

Fig. 2: oneVPL dispatching mechanism

The time stamp of a bitstream buffer must be accurate to the first byte of the frame data. For H.264 the first byte of the frame data comes from the NAL unit in the video coding layer. For MPEG-2 or VC-1 the first byte of the frame data comes from the picture header. DECODE passes the time stamp to the output surface for audio and video multiplexing or synchronization.

Decoding the first frame is a special case because DECODE does not provide enough configuration parameters to correctly process the bitstream. DECODE searches for the sequence header (a sequence parameter set in H.264 or a sequence header in MPEG-2 and VC-1) that contains the video configuration parameters used to encode subsequent video frames. The decoder skips any bitstream prior to the sequence header. In the case of multiple sequence headers in the bitstream, DECODE adopts the new configuration parameters, ensuring proper decoding of subsequent frames.

DECODE supports repositioning of the bitstream at any time during decoding. Because there is no way to obtain the correct sequence header associated with the specified bitstream position after a position change, the application must supply DECODE with a sequence header before the decoder can process the next frame at the new position. If the sequence header required to correctly decode the bitstream at the new position is not provided by the application, DECODE treats the new location as a new “first frame” and follows the procedure for decoding first frames.

10.2.2 Video Encoding

The *ENCODE* class of functions take raw frames as input and compresses them into a bitstream.

Input frames usually come encoded in a repeated pattern called the Group of Picture (GOP) sequence. For example, a GOP sequence can start with an I-frame followed by a few B-frames, a P-frame, and so on. ENCODE uses an MPEG-2 style GOP sequence structure that can specify the length of the sequence and the distance between two keyframes: I- or P-frames. A GOP sequence ensures that the segments of a bitstream do not completely depend upon each other. It also enables decoding applications to reposition the bitstream.

ENCODE processes input frames in two ways;

- **Display order:** ENCODE receives input frames in the display order. GOP structure parameters specify the GOP sequence during ENCODE initialization. Scene changes resulting from the video processing stage of a pipeline can alter the GOP sequence.
- **Encoded order:** ENCODE receives input frames in their encoding order. The application must specify the exact input frame type for encoding. ENCODE references GOP parameters to determine when to insert information, such as an end-of-sequence, into the bitstream.

An ENCODE output consists of one frame of a bitstream with the time stamp passed from the input frame. The time stamp is used for multiplexing subsequent video with other associated data such as audio. oneVPL provides only pure

video stream encoding. The application must provide its own multiplexing.

ENCODE supports the following bitrate control algorithms: constant bitrate, variable bitrate (VBR), and constant quantization parameter (QP). In the constant bitrate mode, ENCODE performs stuffing when the size of the least-compressed frame is smaller than what is required to meet the hypothetical reference decoder (HRD) buffer requirements (or VBR requirements). (Stuffing is a process that appends zeros to the end of encoded frames.)

10.2.3 Video Processing

Video processing functions (*VPP*) take raw frames as input and provide raw frames as output.

The actual conversion process is a chain operation with many single-function filters.

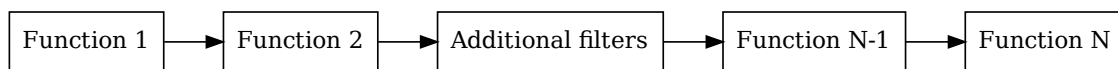

Fig. 3: Video processing operation pipeline

The application specifies the input and output format; oneVPL configures the pipeline according to the specified input and output formats. The application can also attach one or more hint structures to configure individual filters or turn them on and off. Unless specifically instructed, oneVPL builds the pipeline in a way that best utilizes hardware acceleration or generates the best video processing quality.

The *Video Processing Features table* shows oneVPL video processing features. The application can configure supported video processing features through the video processing I/O parameters. The application can also configure optional features through hints. See *Video Processing Procedures* for more details on how to configure optional filters.

Table 1: Video Processing Features

Video Processing Features	Configuration
Convert color format from input to output	I/O parameters
De-interlace to produce progressive frames at the output	I/O parameters
Crop and resize the input frames	I/O parameters
Convert input frame rate to match the output	I/O parameters
Perform inverse telecine operations	I/O parameters
Fields weaving	I/O parameters
Fields splitting	I/O parameters
Remove noise	Hint (optional feature)
Enhance picture details/edges	Hint (optional feature)
Adjust the brightness, contrast, saturation, and hue settings	Hint (optional feature)
Perform image stabilization	Hint (optional feature)
Convert input frame rate to match the output, based on frame interpolation	Hint (optional feature)
Perform detection of picture structure	Hint (optional feature)

10.2.4 Video Decoding with multiple video processing

The *DECODE_VPP* class of functions take a compressed bitstream as input, converts it to raw frames and applies video processing filters to raw frames. Users can set several output channels where each channel represents a list of video processing filters applied for decoded frames.

The *DECODE_VPP* supports only internal allocation.

10.3 Programming Guide

This chapter describes the concepts used in programming with oneVPL.

The application must use the include file `mfx.h` for C/C++ programming and link the oneVPL dispatcher library `libvpl.so`.

Include these files:

```
#include "mfx.h"    /* oneVPL include file */
```

Link this library:

```
libvpl.so          /* oneVPL dynamic dispatcher library (Linux\*) */
```

10.3.1 Status Codes

The oneVPL functions are organized into categories for easy reference. The categories include *ENCODE* (encoding functions), *DECODE* (decoding functions), and *VPP* (video processing functions).

Init, **Reset**, and **Close** are member functions within the ENCODE, DECODE, and VPP classes that initialize, restart, and deinitialize specific operations defined for the class. Call all member functions of a given class within the **Init - Reset - Close** sequence, except **Query** and **QueryIOSurf**. **Reset** functions are optional within the sequence.

The **Init** and **Reset** member functions set up necessary internal structures for media processing. **Init** functions allocate memory and **Reset** functions only reuse allocated internal memory. If oneVPL needs to allocate additional memory, **Reset** can fail. **Reset** functions can also fine-tune ENCODE and VPP parameters during those processes or reposition a bitstream during DECODE.

All oneVPL functions return status codes to indicate if an operation succeeded or failed. The `mfxStatus::MFX_ERR_NONE` status code indicates that the function successfully completed its operation. Error status codes are less than `mfxStatus::MFX_ERR_NONE` and warning status codes are greater than `mfxStatus::MFX_ERR_NONE`. See the `mfxStatus` enumerator for all defined status codes.

If a oneVPL function returns a warning, it has sufficiently completed its operation. Note that the output of the function might not be strictly reliable. The application must check the validity of the output generated by the function.

If a oneVPL function returns an error (except `mfxStatus::MFX_ERR_MORE_DATA`, `mfxStatus::MFX_ERR_MORE_SURFACE`, or `mfxStatus::MFX_ERR_MORE_BITSTREAM`), the function aborts the operation. The application must call either the **Reset** function to reset the class back to a clean state or the **Close** function to terminate the operation. The behavior is undefined if the application continues to call any class member functions without a **Reset** or **Close**. To avoid memory leaks, always call the **Close** function after **Init**.

10.3.2 oneVPL Session

Before calling any oneVPL functions, the application must initialize the library and create a oneVPL session. A oneVPL session maintains context for the use of any of *DECODE*, *ENCODE*, *VPP*, *DECODE_VPP* functions.

Intel® Media Software Development Kit Dispatcher (Legacy)

The *MFXInit()* or *MFXInitEx()* function starts (initializes) a session. The *MFXClose()* function closes (de-initializes) the session. To avoid memory leaks, always call *MFXClose()* after *MFXInit()*.

Important: *MFXInit()* and *MFXInitEx()* are deprecated starting from API 2.0. Applications must use *MFXLoad()* and *MFXCreateSession()* to initialize implementations.

Important: For backward compatibility with existent Intel® Media Software Development Kit applications oneVPL session can be created and initialized by the legacy dispatcher through *MFXInit()* or *MFXInitEx()* calls. In this case, the reported API version will be 1.255 on Intel® platforms with X^e architecture.

The application can initialize a session as a software-based session (*MFX_IMPL_SOFTWARE*) or a hardware-based session (*MFX_IMPL_HARDWARE*). In a software-based session, the SDK functions execute on a CPU. In a hardware-based session, the SDK functions use platform acceleration capabilities. For platforms that expose multiple graphic devices, the application can initialize a session on any alternative graphic device using the *MFX_IMPL_HARDWARE*, *MFX_IMPL_HARDWARE2*, *MFX_IMPL_HARDWARE3*, or *MFX_IMPL_HARDWARE4* values of *mfxmlpl*.

The application can also initialize a session to be automatic (*MFX_IMPL_AUTO* or *MFX_IMPL_AUTO_ANY*), instructing the dispatcher library to detect the platform capabilities and choose the best SDK library available. After initialization, the SDK returns the actual implementation through the *MFXQueryIMPL()* function.

Internally, the dispatcher works as follows:

1. Dispatcher searches for the shared library with the specific name:

OS	Name	Description
Linux*	libmfxsw64.so.1	64-bit software-based implementation
Linux	libmfxsw32.so.1	32-bit software-based implementation
Linux	libmfxhw64.so.1	64-bit hardware-based implementation
Linux	libmfxhw32.so.1	32-bit hardware-based implementation
Windows*	libmfxsw32.dll	64-bit software-based implementation
Windows	libmfxsw32.dll	32-bit software-based implementation
Windows	libmfxhw64.dll	64-bit hardware-based implementation
Windows	libmfxhw32.dll	32-bit hardware-based implementation

2. Once the library is loaded, the dispatcher obtains addresses for each SDK function. See the *Exported Functions/API Version table* for the list of functions to expose.

How the shared library is identified using the implementation search strategy will vary according to the OS.

- On Windows, the dispatcher searches the following locations, in the specified order, to find the correct implementation library:
 1. The **Driver Store** directory for the current adapter. All types of graphics drivers can install libraries in this directory. [Learn more about Driver Store](#).
 2. The directory specified for the current hardware under the registry key HKEY_CURRENT_USER\Software\Intel\MediaSDK\Dispatch.

3. The directory specified for the current hardware under the registry key `HKEY_LOCAL_MACHINE\Software\Intel\MediaSDK\Dispatch`.
4. The directory that is stored in these registry keys: `C:\Program Files\Intel\Media SDK`. This directory is where legacy graphics drivers install libraries.
5. The directory where the current module (the module that links the dispatcher) is located (only if the current module is a dll).

After the dispatcher completes the main search, it additionally checks:

1. The directory of the exe file of the current process, where it looks for software implementation only, regardless of which implementation the application requested.
 2. Default dll search. This provides loading from the directory of the application's exe file and from the `System32` and `SysWOW64` directories. [Learn more about default dll search order.](#)
 3. The `System32` and `SysWOW64` directories, which is where DCH graphics drivers install libraries.
- On Linux, the dispatcher searches the following locations, in the specified order, to find the correct implementation library:
 1. Directories provided by the environment variable `LD_LIBRARY_PATH`.
 2. Content of the `/etc/ld.so.cache` file.
 3. Default path `/lib`, then `/usr/lib` or `/lib64`, and then `/usr/lib64` on some 64 bit OSs. On Debian: `/usr/lib/x86_64-linux-gnu`.
 4. SDK installation folder.

oneVPL Dispatcher

The oneVPL dispatcher extends the legacy dispatcher by providing additional ability to select the appropriate implementation based on the implementation capabilities. Implementation capabilities include information about supported decoders, encoders, and VPP filters. For each supported encoder, decoder, and filter, capabilities include information about supported memory types, color formats, and image (frame) size in pixels.

The recommended approach to configure the dispatcher's capabilities search filters and to create a session based on a suitable implementation is as follows:

1. Create loader with `MFXLoad()`.
2. Create loader's configuration with `MFXCreateConfig()`.
3. Add configuration properties with `MFXSetConfigFilterProperty()`.
4. Explore available implementations with `MFXEnumImplementations()`.
5. Create a suitable session with `MFXCreateSession()`.

The procedure to terminate an application is as follows:

1. Destroy session with `MFXClose()`.
2. Destroy loader with `MFXUnload()`.

Note: Multiple loader instances can be created.

Note: Each loader may have multiple configuration objects associated with it. When a configuration object is modified through `MFxSetConfigFilterProperty()` it implicitly impacts the state and configuration of the associated loader.

Important: One configuration object can handle only one filter property.

Note: Multiple sessions can be created by using one loader object.

When the dispatcher searches for the implementation, it uses the following priority rules:

1. Hardware implementation has priority over software implementation.
 2. General hardware implementation has priority over VSI hardware implementation.
 3. Highest API version has higher priority over lower API version.
-

Note: Implementation has priority over the API version. In other words, the dispatcher must return the implementation with the highest API priority (greater than or equal to the implementation requested).

How the shared library is identified using the implementation search strategy will vary according to the OS.

- On Windows, the dispatcher searches the following locations, in the specified order, to find the correct implementation library:
 1. The `Driver Store` directory for all available adapters. All types of graphics drivers can install libraries in this directory. [Learn more about Driver Store](#). Applicable only for Intel implementations.
 2. The directory of the exe file of the current process.
 3. Current working directory.
 4. `PATH` environmental variable.
 5. For backward compatibility with older spec versions, dispatcher also checks user-defined search folders which are provided by `ONEVPL_SEARCH_PATH` environmental variable.
 - On Linux, the dispatcher searches the following locations, in the specified order, to find the correct implementation library:
 1. Directories provided by the environment variable `LD_LIBRARY_PATH`.
 2. Default path `/lib`, then `/usr/lib` or `/lib64`, and then `/usr/lib64` on some 64 bit OSs. On Debian: `/usr/lib/x86_64-linux-gnu`.
 3. Current working directory.
 4. For backward compatibility with older spec versions, dispatcher also checks user-defined search folders which are provided by `ONEVPL_SEARCH_PATH` environmental variable.
-

Important: To prioritize loading of custom oneVPL library, users may set environment variable `ONEVPL_PRIORITY_PATH` with the path to the user-defined folder. All libraries found in the `ONEVPL_PRIORITY_PATH` have the same priority (higher than any others, and HW/SW or API version rules are not applied) and should be loaded/filtered according to `MFxSetConfigFilterProperty()`.

When oneVPL dispatcher searches for the legacy Intel® Media Software Development Kit implementation it uses *legacy dispatcher search order*.

The dispatcher supports different software implementations. The user can use the *mfImplDescription::VendorID* field, the *mfImplDescription::VendorImplID* field, or the *mfImplDescription::ImplName* field to search for the specific implementation.

Internally, the dispatcher works as follows:

1. Dispatcher loads all shared libraries in the given search folders, whose names match any of the patterns in the following table:

Windows 64-bit	Windows 32-bit	Linux 64-bit	Description
libvpl*.dll	libvpl*.dll	libvpl*.so*	Runtime library for any platform
libmfx64-gen.dll	libmfx32-gen.dll	libmfx-gen.so.1.2	Runtime library for oneVPL for Intel® platforms with X ^c architecture
libm-fxhw64.dll	libm-fxhw32.dll	libm-fxhw64.so.1	Runtime library for Intel® Media Software Development Kit

2. For each loaded library, the dispatcher tries to resolve address of the *MFXQueryImplsDescription()* function to collect the implementation’s capabilities.
3. Once the user has requested to create the session based on this implementation, the dispatcher obtains addresses of each oneVPL function. See the *Exported Functions/API Version table* for the list of functions to export.

oneVPL Dispatcher Configuration Properties

The *Dispatcher Configuration Properties Table* shows property strings supported by the dispatcher. Table organized in the hierarchy way, to create the string, go from the left to right from column to column and concatenate strings by using . (dot) as the separator.

Table 2: Dispatcher Configuration Properties

Structure name	Property	Value Data Type	Comment
<i>mfImplDescription</i>	mfImplDescription .Impl	MFX_VARIANT_TYPE_U32	
	mfImplDescription .AccelerationMode	MFX_VARIANT_TYPE_U32	The mode will be used for session initialization
	mfImplDescription .ApiVersion .Version	MFX_VARIANT_TYPE_U32	
	mfImplDescription .ApiVersion .Major	MFX_VARIANT_TYPE_U16	

continues on next page

Table 2 – continued from previous page

Structure name	Property	Value Data Type	Comment
	mfImplDescription .ApiVersion .Minor	MFX_VARIANT_TYPE_U16

	mfxImplDescription .mfxVPPDescription .filter .memdesc .format .OutFormats	MFX_VARIANT_TYPE_U32	

continues on next page

Table 2 – continued from previous page

Structure name	Property	Value Data Type	Comment
<i>mfxImplementedFunctions</i>	mfxImplementedFunctions .FunctionsName	MFX_VARIANT_TYPE_PTR	Pointer to the buffer with string
N/A	DXGIAdapterIndex	MFX_VARIANT_TYPE_U32	Adapter index according to IDXGIFactory::EnumAdapters

Important: DXGIAdapterIndex property is available for Windows only and filters only hardware implementations.

Examples of the property name strings:

- mfxImplDescription.mfxDecoderDescription.decoder.decprofile.Profile
- mfxImplDescription.mfxDecoderDescription.decoder.decprofile.decmemdesc.MemHandleType
- mfxImplementedFunctions.FunctionsName

Following properties are supported in a special manner: they are used to send additional data to the implementation through the dispatcher. Application needs to use *MFxSetConfigFilterProperty()* to set them up but they don't influence on the implementation selection. They are used during the *MFxCreateSession()* function call to fine tune the implementation.

Table 3: Dispatcher's Special Properties

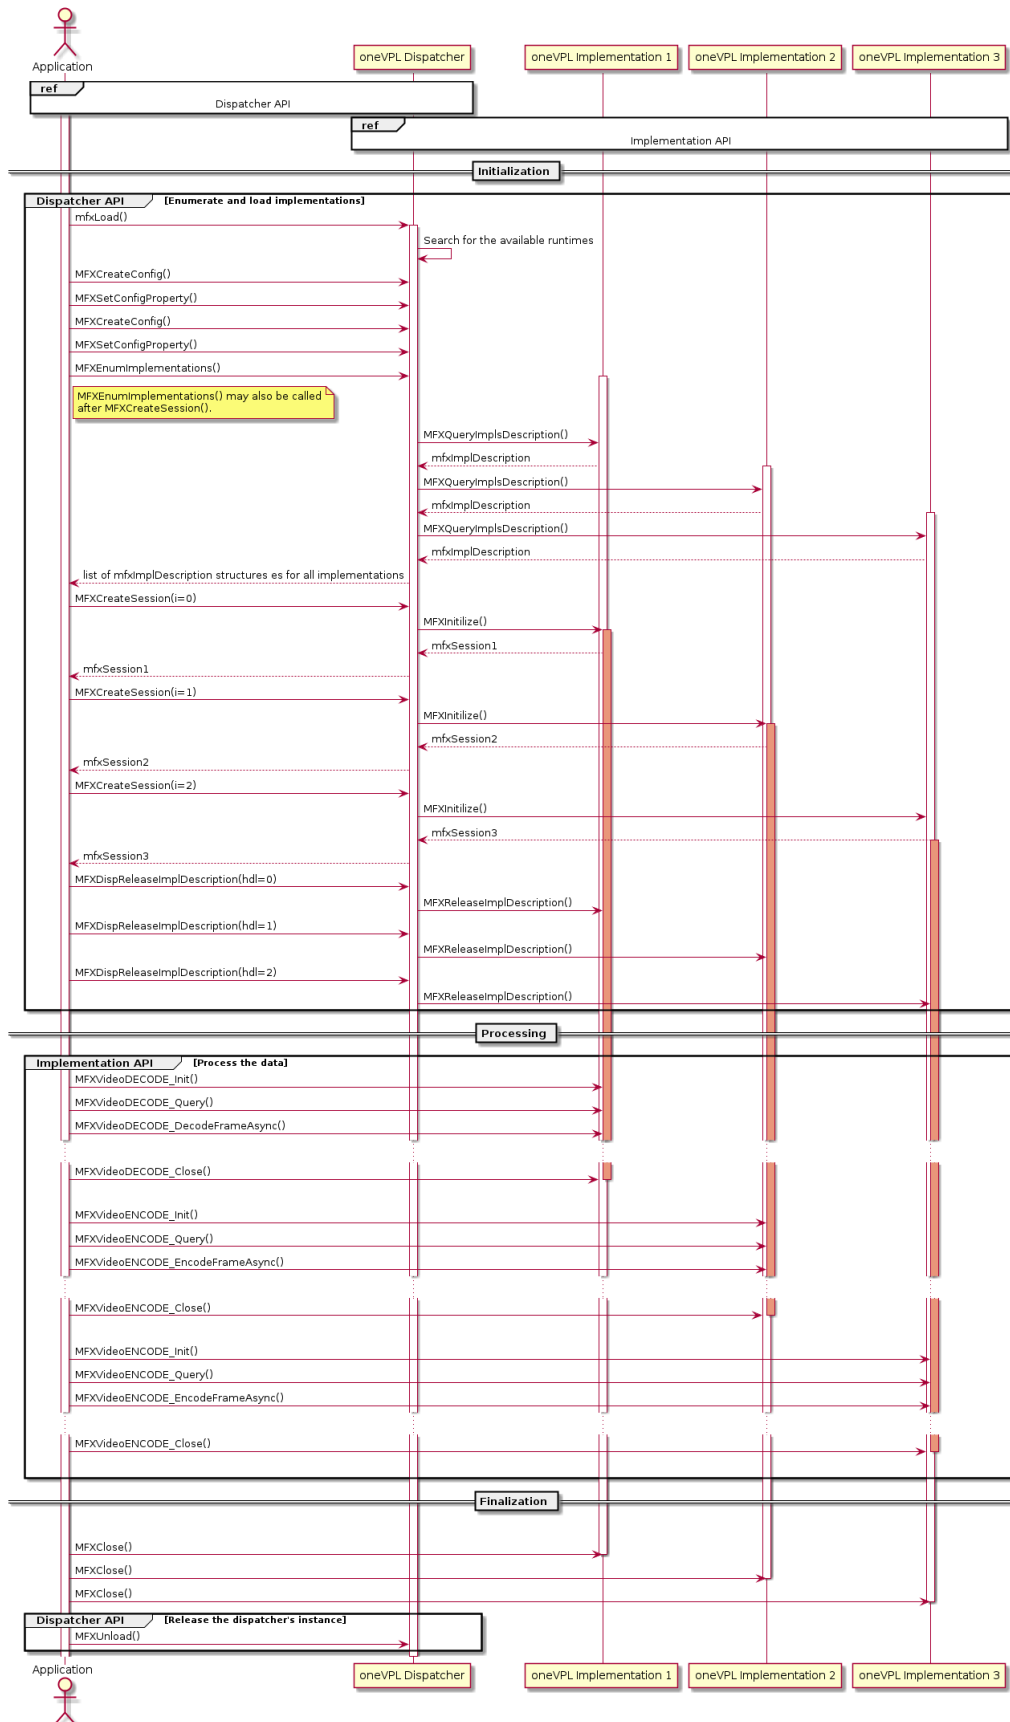

Property Name	Property Value	Value data type
mfxHandleType	<i>mfxHandleType</i>	<i>mfxVariantType::MFx_VARIANT_TYPE_U32</i>
mfxHDL	<i>mfxHDL</i>	<i>mfxVariantType::MFx_VARIANT_TYPE_PTR</i>
NumThread	Unsigned fixed-point integer value	<i>mfxVariantType::MFx_VARIANT_TYPE_U32</i>
DeviceCopy	<i>Device copy</i>	<i>mfxVariantType::MFx_VARIANT_TYPE_U16</i>
ExtBuffer	Pointer to the extension buffer	<i>mfxVariantType::MFx_VARIANT_TYPE_PTR</i>

oneVPL Dispatcher Interactions

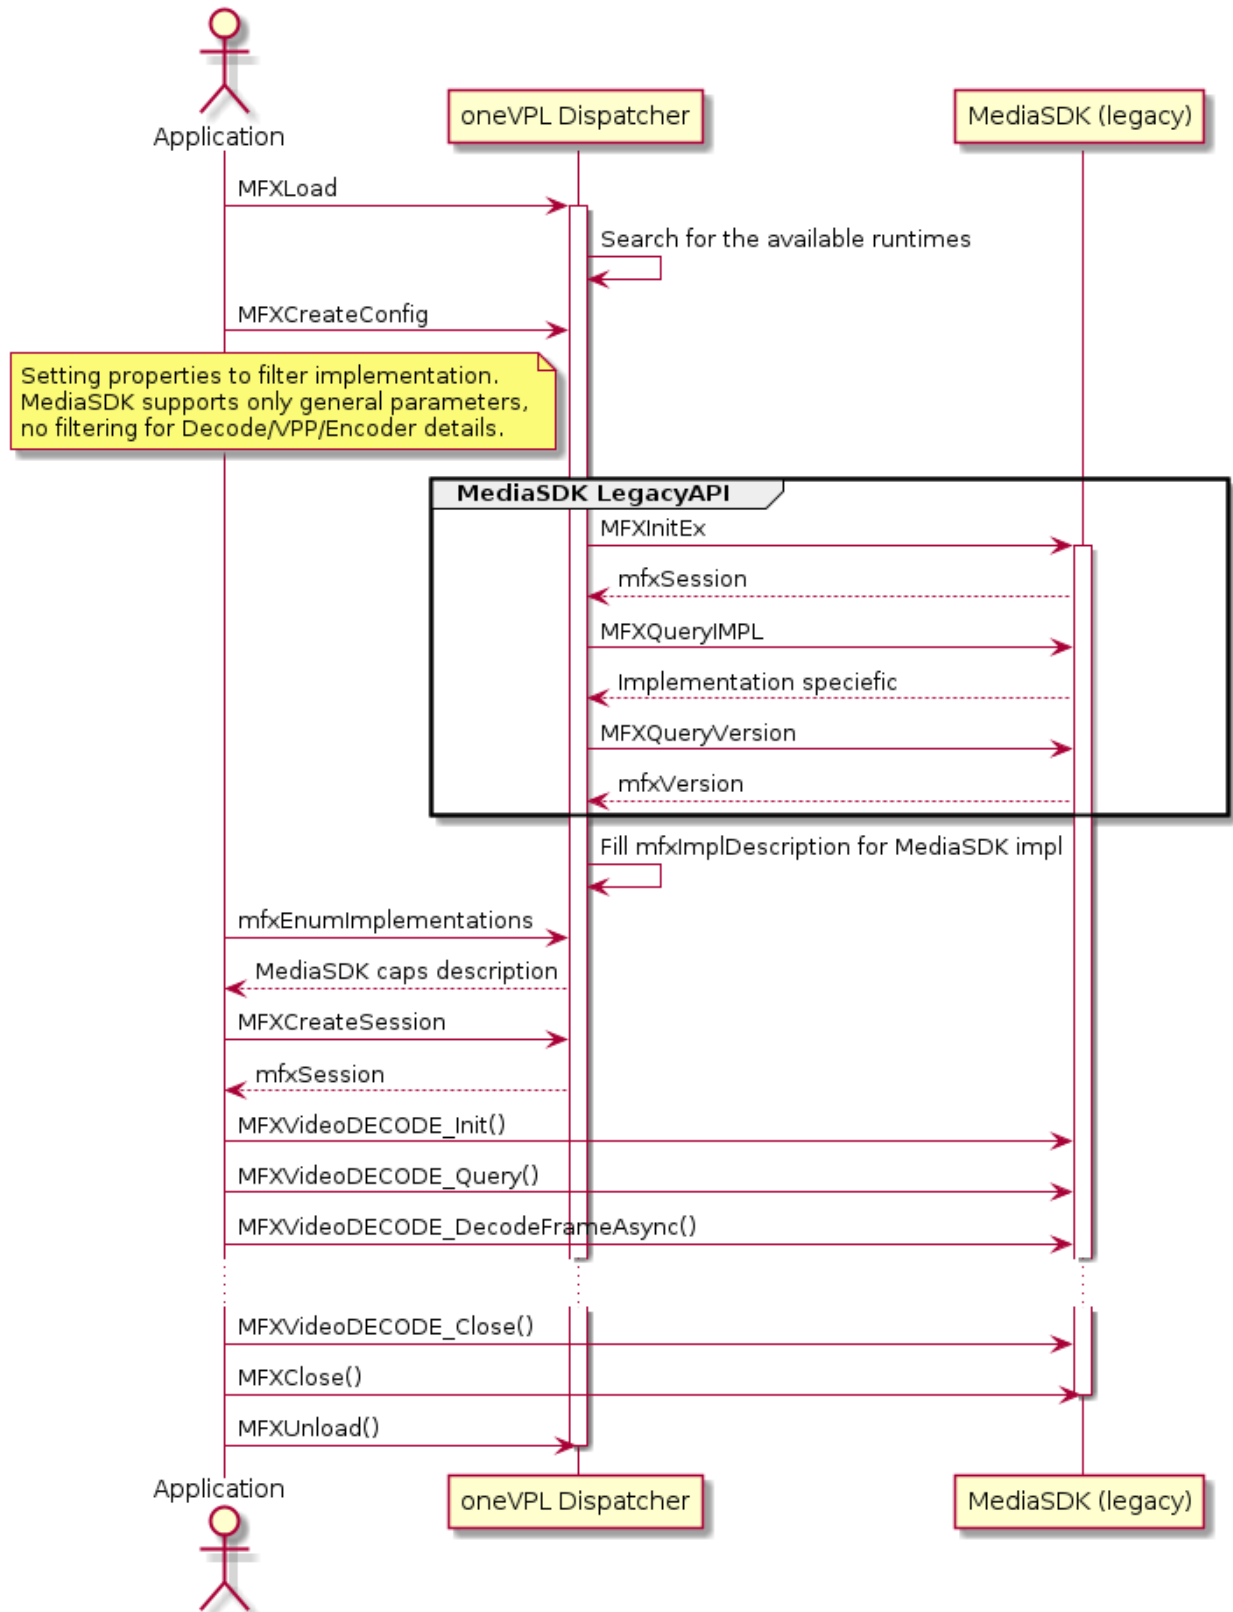

This sequence diagram visualize how application communicates with implementations via the dispatcher.

Dispatcher API This API is implemented in the dispatcher.

Implementation API This API is provided by the any implementation.

The oneVPL dispatcher is capable to load and initialize Intel® Media Software Development Kit legacy library. The sequence diagram below demonstrates the approach.

Important: The dispatcher doesn't filter and report *mfxDDeviceDescription*, *mfxDDecoderDescription*, *mfxDEncoderDescription*, *mfxDVPPDescription* when enumerates or creates Intel® Media Software Development Kit implementation. Once Intel® Media Software Development Kit is loaded applications have to use legacy approach to query capabilities.

oneVPL Dispatcher Debug Log

The debug output of the dispatcher is controlled with the *ONEVPL_DISPATCHER_LOG* environment variable. To enable log output, set the *ONEVPL_DISPATCHER_LOG* environment variable value equals to "ON".

By default, oneVPL dispatcher prints all log messages to the console. To redirect log output to the desired file, set the *ONEVPL_DISPATCHER_LOG_FILE* environmental variable with the file name of the log file.

Examples of Dispatcher's Usage

This code illustrates simple usage of dispatcher to load first available library:

```
1 mfxLoader loader = MFXLoad();
2 MFXCreateSession(loader, 0, &session);
```

This code illustrates simple usage of dispatcher to load first available HW accelerated library:

```
1 mfxLoader loader = MFXLoad();
2 mfxConfig cfg = MFXCreateConfig(loader);
3 mfxVariant ImplValue;
4 ImplValue.Type = MFX_VARIANT_TYPE_U32;
5 ImplValue.Data.U32 = MFX_IMPL_TYPE_HARDWARE;
6 MFXSetConfigFilterProperty(cfg, (const mfxU8 *)"mfxImplDescription.Impl", ImplValue);
7 MFXCreateSession(loader, 0, &session);
```

This code illustrates how multiple sessions from multiple loaders can be created:

```
1 // Create session with software based implementation
2 mfxLoader loader1 = MFXLoad();
3 mfxConfig cfg1 = MFXCreateConfig(loader1);
4 mfxVariant ImplValueSW;
5 ImplValueSW.Type = MFX_VARIANT_TYPE_U32;
6 ImplValueSW.Data.U32 = MFX_IMPL_TYPE_SOFTWARE;
7 MFXSetConfigFilterProperty(cfg1, (const mfxU8 *)"mfxImplDescription.Impl", ImplValueSW);
8 MFXCreateSession(loader1, 0, &sessionSW);
9
10 // Create session with hardware based implementation
11 mfxLoader loader2 = MFXLoad();
12 mfxConfig cfg2 = MFXCreateConfig(loader2);
13 mfxVariant ImplValueHW;
14 ImplValueHW.Type = MFX_VARIANT_TYPE_U32;
15 ImplValueHW.Data.U32 = MFX_IMPL_TYPE_HARDWARE;
16 MFXSetConfigFilterProperty(cfg2, (const mfxU8 *)"mfxImplDescription.Impl", ImplValueHW);
17 MFXCreateSession(loader2, 0, &sessionHW);
18
19 // use both sessionSW and sessionHW
```

(continues on next page)

(continued from previous page)

```

20 // ...
21 // Close everything
22 MFXClose(sessionSW);
23 MFXClose(sessionHW);
24 MFXUnload(loader1); // cfg1 will be destroyed here.
25 MFXUnload(loader2); // cfg2 will be destroyed here.

```

This code illustrates how multiple decoders from single loader can be created:

```

1  mfxLoader loader = MFXLoad();
2
3  // We want to have AVC decoder supported.
4  mfxConfig cfg1 = MFXCreateConfig(loader);
5  mfxVariant ImplValue;
6  ImplValue.Type = MFX_VARIANT_TYPE_U32;
7  ImplValue.Data.U32 = MFX_CODEC_AVC;
8  MFXSetConfigFilterProperty(cfg1,
9      (const mfxU8 *)"mfxImplDescription.mfxDecoderDescription.decoder.CodecID",
10     ↪ImplValue);
11
12 // And we want to have HEVC encoder supported by the same implementation.
13 mfxConfig cfg2 = MFXCreateConfig(loader);
14 ImplValue.Type = MFX_VARIANT_TYPE_U32;
15 ImplValue.Data.U32 = MFX_CODEC_HEVC;
16 MFXSetConfigFilterProperty(cfg2,
17     (const mfxU8 *)"mfxImplDescription.mfxEncoderDescription.encoder.CodecID",
18     ↪ImplValue);
19
20 // To create single session with both capabilities.
21 MFXCreateSession(loader, 0, &session);

```

How To Check If Function is Implemented

There are two ways to check if particular function is implemented or not by the implementation.

This code illustrates how application can iterate through the whole list of implemented functions:

```

1  mfxHDL h;
2  // request pointer to the list. Assume that implementation supports that.
3  // Assume that `loader` is configured before.
4  mfxStatus sts = MFXEnumImplementations(loader, idx, MFX_IMPLCAPS_IMPLEMENTEDFUNCTIONS, &
5     ↪h);
6  // break if no idx
7  if (sts != MFX_ERR_NOT_FOUND) {
8      // Cast typeless handle to structure pointer
9      mfxImplementedFunctions *implemented_functions = (mfxImplementedFunctions*)h;
10
11     // print out list of functions' name
12     std::for_each(implemented_functions->FunctionsName, implemented_functions->
13     ↪FunctionsName +
14
15                                     implemented_functions->
16     ↪NumFunctions,

```

(continues on next page)

(continued from previous page)

```

13     [](mfxChar* functionName) {
14         std::cout << functionName << " is implemented" << std::endl;
15     });
16     // Release resource
17     MFXDispReleaseImplDescription(loader, h);
18 }

```

This code illustrates how application can check that specific functions are implemented:

```

1  mfxSession session_handle;
2  loader = mfxLoader();
3
4  // We want to search for the implementation with Decode+VPP domain functions support.
5  // i.e we search for the MFXVideoDECODE_VPP_Init and MFXVideoDECODE_VPP_DecodeFrameAsync
6  // implemented functions
7  mfxConfig init_func_prop = MFXCreateConfig(loader);
8  mfxVariant value;
9
10 // Filter property for the Init function
11 value.Type = mfxVariantType::MFX_VARIANT_TYPE_PTR;
12 value.Data.Ptr = (mfxHDL)"MFXVideoDECODE_VPP_Init";
13 MFXSetConfigFilterProperty(init_func_prop, (const mfxU8*)"mfxImplementedFunctions.
14 ↪FunctionsName",
15                             value);
16
17 // Filter property for the Process function
18 mfxConfig process_func_prop = MFXCreateConfig(loader);
19 value.Data.Ptr = (mfxHDL)"MFXVideoDECODE_VPP_DecodeFrameAsync";
20 MFXSetConfigFilterProperty(process_func_prop, (const mfxU8*)"mfxImplementedFunctions.
21 ↪FunctionsName",
22                             value);
23
24 // create session from first matched implementation
25 MFXCreateSession(loader, 0, &session_handle);

```

How To Search For The Available encoder/decoder implementation

The *CodecFormatFourCC* enum specifies codec's FourCC values. Application needs to assign this value to the field of *mfxDecoderDescription::decoder::CodecID* to search for the decoder or *mfxEncoderDescription::encoder::CodecID* to search for the encoder.

This code illustrates decoder's implementation search procedure:

```

1  mfxSession hevc_session_handle;
2  loader = mfxLoader();
3
4  // We want to search for the HEVC decoder implementation
5  mfxConfig hevc_decoder_config = MFXCreateConfig(loader);
6  mfxVariant value;
7
8  // Filter property for the implementations with HEVC decoder
9  value.Type = MFX_VARIANT_TYPE_U32;

```

(continues on next page)

(continued from previous page)

```

10 value.Data.U32 = MFX_CODEC_HEVC;
11
12 MFXSetConfigFilterProperty(hevc_decoder_config
13     , (const mfxU8*)"mfxImplDescription.mfxDecoderDescription.decoder.CodecID"
14     , value);
15
16 // create session from first matched implementation
17 MFXCreateSession(loader, 0, &hevc_session_handle);

```

How To Search For The Available VPP Filter implementation

Each VPP filter identified by the filter ID. Filter ID is defined by corresponding to the filter extension buffer ID value which is defined in a form of FourCC value. Filter ID values are subset of the general *ExtendedBufferID* enum. The *table* references available IDs of VPP filters to search. Application needs to assign this value to the field of *mfxVPPDescription::filter::FilterFourCC* to search for the needed VPP filter.

Table 4: VPP Filters ID

Filter ID	Description
<i>MFX_EXTBUFF_VPP_DENOISE2</i>	Denoise filter
<i>MFX_EXTBUFF_VPP_MCTF</i>	Motion-Compensated Temporal Filter (MCTF).
<i>MFX_EXTBUFF_VPP_DETAIL</i>	Detail/edge enhancement filter.
<i>MFX_EXTBUFF_VPP_FRAME_RATE_CONVERSION</i>	Frame rate conversion filter
<i>MFX_EXTBUFF_VPP_IMAGE_STABILIZATION</i>	Image stabilization filter
<i>MFX_EXTBUFF_VPP_PROCAMP</i>	ProcAmp filter
<i>MFX_EXTBUFF_VPP_FIELD_PROCESSING</i>	Field processing filter
<i>MFX_EXTBUFF_VPP_COLOR_CONVERSION</i>	Color Conversion filter
<i>MFX_EXTBUFF_VPP_SCALING</i>	Resize filter
<i>MFX_EXTBUFF_VPP_COMPOSITE</i>	Surfaces composition filter
<i>MFX_EXTBUFF_VPP_DEINTERLACING</i>	Deinterlace filter
<i>MFX_EXTBUFF_VPP_ROTATION</i>	Rotation filter
<i>MFX_EXTBUFF_VPP_MIRRORING</i>	Mirror filter
<i>MFX_EXTBUFF_VPP_COLORFILL</i>	ColorFill filter

This code illustrates VPP mirror filter implementation search procedure:

```

1 mfxSession mirror_session_handle;
2 loader = mfxLoader();
3
4 // We want to search for the VPP mirror implementation
5 mfxConfig mirrorflt_config = MFXCreateConfig(loader);
6 mfxVariant value;
7
8 // Filter property for the implementations with VPP mirror
9 value.Type = MFX_VARIANT_TYPE_U32;
10 value.Data.U32 = MFX_EXTBUFF_VPP_MIRRORING;
11
12 MFXSetConfigFilterProperty(mirrorflt_config
13     , (const mfxU8*)"mfxImplDescription.mfxVPPDescription.filter.FilterFourCC"
14     , value);

```

(continues on next page)

(continued from previous page)

```

15
16 // create session from first matched implementation
17 MFXCreateSession(loader, 0, &mirror_session_handle);

```

How To Get Path to the Shared Library With the Implementation

Sessions can be created from different implementations, each implementations can be located in different shared libraries. To get path of the shared library with the implementation from which session can be or was created, application can use `MFXEnumImplementations()` and pass `MFX_IMPLCAPS_IMPLPATH` value as the output data request.

This code illustrates collection and print out path of implementations's shared library:

```

1 mfxHDL h;
2 mfxSession def_session;
3
4 loader = mfxLoader();
5
6 // Create session from the first available implementation.
7 // That's why we no any filters need to be set.
8 // First available implementation has index equal to the 0.
9 MFXCreateSession(loader, 0, &def_session);
10
11 // Get and print out OS path to the loaded shared library
12 // with the implementation. It is absolutely OK to call
13 // MFXEnumImplementations after session creation just need to make
14 // sure that the same index of implementation is provided to the
15 // function call.
16 MFXEnumImplementations(loader, 0, MFX_IMPLCAPS_IMPLPATH, &h);
17 mfxChar* path = reinterpret_cast<mfxChar*>(h);
18
19 // Print out the path
20 std::cout << "Loaded shared library: " << path << std::endl;
21
22 // Release the memory for the string with path.
23 MFXDispReleaseImplDescription(loader, h);

```

oneVPL implementation on Intel® platforms with Xe architecture and Intel® Media Software Development Kit Coexistence

oneVPL supersedes Intel® Media Software Development Kit and is partially binary compatible with Intel® Media Software Development Kit. Both oneVPL and Intel® Media Software Development Kit includes own dispatcher and implementation. Coexistence of oneVPL and Intel® Media Software Development Kit dispatchers and implementations on single system is allowed until Intel® Media Software Development Kit is not EOL.

Usage of the following combinations of dispatchers and implementations within the single application is permitted for the legacy purposes only. In that scenario legacy applications developed with Intel® Media Software Development Kit will continue to work on any HW supported either by Intel® Media Software Development Kit or by the oneVPL.

Attention: Any application to work with the oneVPL API starting from version 2.0 must use only oneVPL dispatcher.

Intel® Media Software Development Kit API Intel® Media Software Development Kit API of 1.x version.

Removed API Intel® Media Software Development Kit *API* which is removed from oneVPL.

Core API Intel® Media Software Development Kit API without removed API.

oneVPL API New *API* introduced in oneVPL only started from API 2.0 version.

oneVPL Dispatcher API Dispatcher *API* introduced in oneVPL in 2.0 API version. This is subset of oneVPL API.

Table 5: oneVPL for Intel® platforms with X^e architecture and Intel® Media Software Development Kit

Dispatcher	Installed on the device	Loaded	Allowed API
oneVPL	oneVPL for Intel® platforms with X ^e architecture	oneVPL for Intel® platforms with X ^e architecture	Usage of any API except removed API is allowed.
oneVPL	Intel® Media Software Development Kit	Intel® Media Software Development Kit	Usage of core API plus dispatcher API is allowed only.
oneVPL	oneVPL for Intel® platforms with X ^e architecture and Intel® Media Software Development Kit	oneVPL for Intel® platforms with X ^e architecture	Usage of any API except removed API is allowed.
Intel® Media Software Development Kit	oneVPL for Intel® platforms with X ^e architecture	oneVPL for Intel® platforms with X ^e architecture	Usage of core API is allowed only.
Intel® Media Software Development Kit	oneVPL for Intel® platforms with X ^e architecture and Intel® Media Software Development Kit	Intel® Media Software Development Kit	Usage of Intel® Media Software Development Kit API is allowed.
Intel® Media Software Development Kit	Intel® Media Software Development Kit	Intel® Media Software Development Kit	Usage of Intel® Media Software Development Kit API is allowed.

Note: if system has multiple devices the logic of selection and loading implementations will be applied to each device accordingly to the system enumeration.

Multiple Sessions

Each oneVPL session can run exactly one instance of the DECODE, ENCODE, and VPP functions. This is adequate for a simple transcoding operation. If the application needs more than one instance of DECODE, ENCODE, or VPP in a complex transcoding setting or needs more simultaneous transcoding operations, the application can initialize multiple oneVPL sessions created from one or several oneVPL implementations.

The application can use multiple oneVPL sessions independently or run a “joined” session. To join two sessions together, the application can use the function *MFXJoinSession()*. Alternatively, the application can use the *MFXCloneSession()* function to duplicate an existing session. Joined oneVPL sessions work together as a single session, sharing all session resources, threading control, and prioritization operations except hardware acceleration devices and external allocators. When joined, the first session (first join) serves as the parent session and will schedule execution resources with all other child sessions. Child sessions rely on the parent session for resource management.

Important: Applications can join sessions created from the same oneVPL implementation only.

With joined sessions, the application can set the priority of session operations through the `MFxSetPriority()` function. A lower priority session receives fewer CPU cycles. Session priority does not affect hardware accelerated processing.

After the completion of all session operations, the application can use the `MFxDisjoinSession()` function to remove the joined state of a session. Do not close the parent session until all child sessions are disjoined or closed.

10.3.3 Frame and Fields

In oneVPL terminology, a frame (also referred to as frame surface) contains either a progressive frame or a complementary field pair. If the frame is a complementary field pair, the odd lines of the surface buffer store the top fields and the even lines of the surface buffer store the bottom fields.

Frame Surface Management

During encoding, decoding, or video processing, cases arise that require reserving input or output frames for future use. For example, when decoding, a frame that is ready for output must remain as a reference frame until the current sequence pattern ends. The usual method to manage this is to cache the frames internally. This method requires a copy operation, which can significantly reduce performance.

oneVPL has two approaches to avoid the need for copy operations. The legacy approach uses a frame-locking mechanism that works as follows:

1. The application allocates a pool of frame surfaces large enough to include oneVPL function I/O frame surfaces and internal cache needs. Each frame surface maintains a Locked counter, which is part of the `mfxFrameData` structure. The Locked counter is initially set to zero.
2. The application calls a oneVPL function with frame surfaces from the pool whose Locked counter is set as appropriate for the desired operation. For decoding or video processing operations, where oneVPL uses the surfaces to write, the Locked counter should be equal to zero. If the oneVPL function needs to reserve any frame surface, the oneVPL function increases the Locked counter of the frame surface. A non-zero Locked counter indicates that the calling application must treat the frame surface as “in use.” When the frame surface is in use, the application can read but cannot alter, move, delete, or free the frame surface.
3. In subsequent oneVPL executions, if the frame surface is no longer in use, oneVPL decreases the Locked counter. When the Locked counter reaches zero, the application is free to do as it wishes with the frame surface.

In general, the application should not increase or decrease the Locked counter since oneVPL manages this field. If, for some reason, the application needs to modify the Locked counter, the operation must be atomic to avoid a race condition.

oneVPL API version 2.0 introduces the `mfxFrameSurfaceInterface` structure which provides a set of callback functions for the `mfxFrameSurface1` structure to work with frame surfaces. This interface defines `mfxFrameSurface1` as a reference counted object which can be allocated by oneVPL or the application. The application must follow the general rules of operation with reference counted objects. For example, when surfaces are allocated by oneVPL during `MFxVideoDECODE_DecodeFrameAsync()` or with the help of `MFxMemory_GetSurfaceForVPP()` or `MFxMemory_GetSurfaceForVPPOut()` or `MFxMemory_GetSurfaceForEncode()`, the application must call the corresponding `mfxFrameSurfaceInterface::Release` function for the surfaces that are no longer in use.

Attention: Note that the Locked counter defines read/write access policies and the reference counter is responsible for managing a frame’s lifetime.

The second approach to avoid the need for copy operations is based on the `mfxFrameSurfaceInterface` and works as follows:

1. oneVPL or the application allocates a frame surface and the application stores a value of reference counter obtained through `mfxFramSurfaceInterface::GetRefCounter`.
2. The application calls a oneVPL function with the frame surface. If oneVPL needs to reserve the frame surface it increments the reference counter through the `mfxFramSurfaceInterface::AddRef` call. When the frame surface is no longer in use by the oneVPL it decrements reference counter through the `mfxFramSurfaceInterface::Release` call which returns the reference counter to the original value.
3. The application checks the reference counter of the frame surface and when it is equal to the original value after allocation, it can reuse the reference counter for subsequent operations.

Note: All `mfxFramSurface1` structures starting from `mfxFramSurface1::mfxFramStructVersion = {1,1}` support the `mfxFramSurfaceInterface`.

10.3.4 Decoding Procedures

There are several approaches to decode video frames. The first one is based on the internal allocation mechanism presented here:

```

1  MFXVideoDECODE_Init(session, &init_param);
2  sts=MFX_ERR_MORE_DATA;
3  for (;;) {
4      if (sts==MFX_ERR_MORE_DATA && !end_of_stream())
5          append_more_bitstream(bitstream);
6      bits=(end_of_stream())?NULL:bitstream;
7      sts=MFXVideoDECODE_DecodeFrameAsync(session, bits, NULL, &disp, &syncp);
8      if (end_of_stream() && sts==MFX_ERR_MORE_DATA) break;
9      // skipped other error handling
10     if (sts==MFX_ERR_NONE) {
11         disp->FrameInterface->Synchronize(disp, INFINITE); // or MFXVideoCORE_
12         ↪ SyncOperation(session, syncp, INFINITE)
13         do_something_with_decoded_frame(disp);
14         disp->FrameInterface->Release(disp);
15     }
16 }
17 MFXVideoDECODE_Close(session);

```

Note the following key points about the example:

- The application calls the `MFXVideoDECODE_DecodeFrameAsync()` function for a decoding operation with the bitstream buffer (bits), frame surface is allocated internally by the library.

Attention: As shown in the example above starting with API version 2.0, the application can provide NULL as the working frame surface that leads to internal memory allocation.

- If decoding output is not available, the function returns a status code requesting additional bitstream input as follows:
 - `mfxFStatus::MFX_ERR_MORE_DATA`: The function needs additional bitstream input. The existing buffer contains less than a frame's worth of bitstream data.
- Upon successful decoding, the `MFXVideoDECODE_DecodeFrameAsync()` function returns `mfxFStatus::MFX_ERR_NONE`. However, the decoded frame data (identified by the `surface_out` pointer) is

not yet available because the `MFVideoDECODE_DecodeFrameAsync()` function is asynchronous. The application must use the `MFVideoCORE_SyncOperation()` or `mfxFrameSurfaceInterface::Synchronize` to synchronize the decoding operation before retrieving the decoded frame data.

- At the end of the bitstream, the application continuously calls the `MFVideoDECODE_DecodeFrameAsync()` function with a NULL bitstream pointer to drain any remaining frames cached within the decoder until the function returns `mfxStatus::MFX_ERR_MORE_DATA`.
- When application completes the work with frame surface, it must call release to avoid memory leaks.

The next example demonstrates how applications can use internally pre-allocated chunk of video surfaces:

```

1 MFVideoDECODE_QueryIOSurf(session, &init_param, &request);
2 MFVideoDECODE_Init(session, &init_param);
3 for (int i = 0; i < request.NumFrameSuggested; i++) {
4     MFXMemory_GetSurfaceForDecode(session, &work);
5     add_surface_to_pool(work);
6 }
7 sts=MFX_ERR_MORE_DATA;
8 for (;;) {
9     if (sts==MFX_ERR_MORE_DATA && !end_of_stream())
10        append_more_bitstream(bitstream);
11    bits=(end_of_stream())?NULL:bitstream;
12    // application logic to distinguish free and busy surfaces
13    find_free_surface_from_the_pool(&work);
14    sts=MFVideoDECODE_DecodeFrameAsync(session,bits,work,&disp,&syncp);
15    if (end_of_stream() && sts==MFX_ERR_MORE_DATA) break;
16    // skipped other error handling
17    if (sts==MFX_ERR_NONE) {
18        disp->FrameInterface->Synchronize(disp, INFINITE); // or MFVideoCORE_
19    ↪ SyncOperation(session, syncp, INFINITE)
20        do_something_with_decoded_frame(disp);
21        disp->FrameInterface->Release(disp);
22    }
23 }
24 for (int i = 0; i < request.NumFrameSuggested; i++) {
25     get_next_surface_from_pool(&work);
26     work->FrameInterface->Release(work);
27 }
28 MFVideoDECODE_Close(session);

```

Here the application should use the `MFVideoDECODE_QueryIOSurf()` function to obtain the number of working frame surfaces required to reorder output frames. It is also required that `MFXMemory_GetSurfaceForDecode()` call is done after decoder initialization. In the `MFVideoDECODE_DecodeFrameAsync()` the oneVPL library increments reference counter of incoming surface frame so it is required that the application releases frame surface after the call.

Another approach to decode frames is to allocate video frames on-fly with help of `MFXMemory_GetSurfaceForDecode()` function, feed the library and release working surface after `MFVideoDECODE_DecodeFrameAsync()` call.

Attention: Please pay attention on two release calls for surfaces: after `MFVideoDECODE_DecodeFrameAsync()` to decrease reference counter of working surface returned by `MFXMemory_GetSurfaceForDecode()`. After `MFVideoCORE_SyncOperation()` to decrease reference counter of output surface returned by `MFVideoDECODE_DecodeFrameAsync()`.

```

1 MFXVideoDECODE_Init(session, &init_param);
2 sts=MFX_ERR_MORE_DATA;
3 for (;;) {
4     if (sts==MFX_ERR_MORE_DATA && !end_of_stream())
5         append_more_bitstream(bitstream);
6     bits=(end_of_stream())?NULL:bitstream;
7     MFXMemory_GetSurfaceForDecode(session, &work);
8     sts=MFXVideoDECODE_DecodeFrameAsync(session, bits, work, &disp, &syncp);
9     work->FrameInterface->Release(work);
10    if (end_of_stream() && sts==MFX_ERR_MORE_DATA) break;
11    // skipped other error handling
12    if (sts==MFX_ERR_NONE) {
13        disp->FrameInterface->Synchronize(disp, INFINITE); // or MFXVideoCORE_
↪ SyncOperation(session, syncp, INFINITE)
14        do_something_with_decoded_frame(disp);
15        disp->FrameInterface->Release(disp);
16    }
17 }
18 MFXVideoDECODE_Close(session);

```

The following pseudo code shows the decoding procedure according to the legacy mode with external video frames allocation:

```

1 MFXVideoDECODE_DecodeHeader(session, bitstream, &init_param);
2 MFXVideoDECODE_QueryIOSurf(session, &init_param, &request);
3 allocate_pool_of_frame_surfaces(request.NumFrameSuggested);
4 MFXVideoDECODE_Init(session, &init_param);
5 sts=MFX_ERR_MORE_DATA;
6 for (;;) {
7     if (sts==MFX_ERR_MORE_DATA && !end_of_stream())
8         append_more_bitstream(bitstream);
9     find_free_surface_from_the_pool(&work);
10    bits=(end_of_stream())?NULL:bitstream;
11    sts=MFXVideoDECODE_DecodeFrameAsync(session, bits, work, &disp, &syncp);
12    if (sts==MFX_ERR_MORE_SURFACE) continue;
13    if (end_of_stream() && sts==MFX_ERR_MORE_DATA) break;
14    if (sts==MFX_ERR_REALLOC_SURFACE) {
15        MFXVideoDECODE_GetVideoParam(session, &param);
16        realloc_surface(work, param.mfx.FrameInfo);
17        continue;
18    }
19    // skipped other error handling
20    if (sts==MFX_ERR_NONE) {
21        disp->FrameInterface->Synchronize(disp, INFINITE); // or MFXVideoCORE_
↪ SyncOperation(session, syncp, INFINITE)
22        do_something_with_decoded_frame(disp);
23    }
24 }
25 MFXVideoDECODE_Close(session);
26 free_pool_of_frame_surfaces();

```

Note the following key points about the example:

- The application can use the `MFXVideoDECODE_DecodeHeader()` function to retrieve decoding initialization

parameters from the bitstream. This step is optional if the data is retrievable from other sources such as an audio/video splitter.

- The `MFVideoDECODE_DecodeFrameAsync()` function can return following status codes in addition to the described above:
 - `mfStatus::MF_ERR_MORE_SURFACE`: The function needs one more frame surface to produce any output.
 - `mfStatus::MF_ERR_REALLOC_SURFACE`: Dynamic resolution change case - the function needs a bigger working frame surface (work).

The following pseudo code shows the simplified decoding procedure:

```

1 sts=MF_ERR_MORE_DATA;
2 for (;;) {
3     if (sts==MF_ERR_MORE_DATA && !end_of_stream())
4         append_more_bitstream(bitstream);
5     bits=(end_of_stream())?NULL:bitstream;
6     sts=MFVideoDECODE_DecodeFrameAsync(session,bits,NULL,&disp,&syncp);
7     if (sts==MF_ERR_MORE_SURFACE) continue;
8     if (end_of_stream() && sts==MF_ERR_MORE_DATA) break;
9     // skipped other error handling
10    if (sts==MF_ERR_NONE) {
11        disp->FrameInterface->Synchronize(disp, INFINITE); // or MFVideoCORE_
↪ SyncOperation(session, syncp, INFINITE)
12        do_something_with_decoded_frame(disp);
13        disp->FrameInterface->Release(disp);
14    }
15 }

```

oneVPL API version 2.0 introduces a new decoding approach. For simple use cases, when the user wants to decode a stream and does not want to set additional parameters, a simplified procedure for the decoder's initialization has been proposed. In this scenario it is possible to skip explicit stages of a stream's header decoding and the decoder's initialization and instead to perform these steps implicitly during decoding of the first frame. This change also requires setting the additional field `mfBitstream::CodecId` to indicate codec type. In this mode the decoder allocates `mfFrameSurface1` internally, so users should set the input surface to zero.

Bitstream Repositioning

The application can use the following procedure for bitstream repositioning during decoding:

1. Use the `MFVideoDECODE_Reset()` function to reset the oneVPL decoder.
2. Optional: If the application maintains a sequence header that correctly decodes the bitstream at the new position, the application may insert the sequence header to the bitstream buffer.
3. Append the bitstream from the new location to the bitstream buffer.
4. Resume the decoding procedure. If the sequence header is not inserted in the previous steps, the oneVPL decoder searches for a new sequence header before starting decoding.

Broken Streams Handling

Robustness and the capability to handle a broken input stream is an important part of the decoder.

First, the start code prefix (ITU-T* H.264 3.148 and ITU-T H.265 3.142) is used to separate NAL units. Then all syntax elements in the bitstream are parsed and verified. If any of the elements violate the specification, the input bitstream is considered invalid and the decoder tries to re-sync (find the next start code). Subsequent decoder behavior is dependent on which syntax element is broken:

- SPS header is broken: return `mfxfStatus::MFX_ERR_INCOMPATIBLE_VIDEO_PARAM` (HEVC decoder only, AVC decoder uses last valid).
- PPS header is broken: re-sync, use last valid PPS for decoding.
- Slice header is broken: skip this slice, re-sync.
- Slice data is broken: corruption flags are set on output surface.

Many streams have IDR frames with `frame_num != 0` while the specification says that “If the current picture is an IDR picture, `frame_num` shall be equal to 0” (ITU-T H.265 7.4.3).

VUI is also validated, but errors do not invalidate the whole SPS. The decoder either does not use the corrupted VUI (AVC) or resets incorrect values to default (HEVC).

Note: Some requirements are relaxed because there are many streams which violate the strict standard but can be decoded without errors.

Corruption at the reference frame is spread over all inter-coded pictures that use the reference frame for prediction. To cope with this problem you must either periodically insert I-frames (intra-coded) or use the intra-refresh technique. The intra-refresh technique allows recovery from corruptions within a predefined time interval. The main point of intra-refresh is to insert a cyclic intra-coded pattern (usually a row) of macroblocks into the inter-coded pictures, restricting motion vectors accordingly. Intra-refresh is often used in combination with recovery point SEI, where the `recovery_frame_cnt` is derived from the intra-refresh interval. The recovery point SEI message is well described at ITU-T H.264 D.2.7 and ITU-T H.265 D.2.8. If decoding starts from AU associated with this SEI message, then the message can be used by the decoder to determine from which picture all subsequent pictures have no errors. In comparison to IDR, the recovery point message does not mark reference pictures as “unused for reference”.

Besides validation of syntax elements and their constraints, the decoder also uses various hints to handle broken streams:

- If there are no valid slices for the current frame, then the whole frame is skipped.
- The slices which violate slice segment header semantics (ITU-T H.265 7.4.7.1) are skipped. Only the `slice_temporal_mvp_enabled_flag` is checked for now.
- Since LTR (Long Term Reference) stays at DPB until it is explicitly cleared by IDR or MMCO, the incorrect LTR could cause long standing visual artifacts. AVC decoder uses the following approaches to handle this:
 - When there is a DPB overflow in the case of an incorrect MMCO command that marks the reference picture as LT, the operation is rolled back.
 - An IDR frame with `frame_num != 0` can't be LTR.
- If the decoder detects frame gapping, it inserts “fake” (marked as non-existing) frames, updates `FrameNumWrap` (ITU-T H.264 8.2.4.1) for reference frames, and applies the Sliding Window (ITU-T H.264 8.2.5.3) marking process. Fake frames are marked as reference, but since they are marked as non-existing, they are not used for inter-prediction.

VP8 Specific Details

Unlike other oneVPL supported decoders, VP8 can accept only a complete frame as input. The application should provide the complete frame accompanied by the `MFX_BITSTREAM_COMPLETE_FRAME` flag. This is the single specific difference.

JPEG

The application can use the same decoding procedures for JPEG/motion JPEG decoding, as shown in the following pseudo code:

```
// optional; retrieve initialization parameters
MFXVideoDECODE_DecodeHeader(...);
// decoder initialization
MFXVideoDECODE_Init(...);
// single frame/picture decoding
MFXVideoDECODE_DecodeFrameAsync(...);
MFXVideoCORE_SyncOperation(...);
// optional; retrieve meta-data
MFXVideoDECODE_GetUserData(...);
// close
MFXVideoDECODE_Close(...);
```

The `MFXVideoDECODE_Query()` function will return `mfxStatus::MFX_ERR_UNSUPPORTED` if the input bitstream contains unsupported features.

For still picture JPEG decoding, the input can be any JPEG bitstreams that conform to the ITU-T Recommendation T.81 with an EXIF or JFIF header. For motion JPEG decoding, the input can be any JPEG bitstreams that conform to the ITU-T Recommendation T.81.

Unlike other oneVPL decoders, JPEG decoding supports three different output color formats: `NV12`, `YUY2`, and `RGB32`. This support sometimes requires internal color conversion and more complicated initialization. The color format of the input bitstream is described by the `mfxInfoMFX::JPEGChromaFormat` and `mfxInfoMFX::JPEGColorFormat` fields. The `MFXVideoDECODE_DecodeHeader()` function usually fills them in. If the JPEG bitstream does not contain color format information, the application should provide it. Output color format is described by general oneVPL parameters: the `mfxFrameInfo::FourCC` and `mfxFrameInfo::ChromaFormat` fields.

Motion JPEG supports interlaced content by compressing each field (a half-height frame) individually. This behavior is incompatible with the rest of the oneVPL transcoding pipeline, where oneVPL requires fields to be in odd and even lines of the same frame surface. The decoding procedure is modified as follows:

- The application calls the `MFXVideoDECODE_DecodeHeader()` function with the first field JPEG bitstream to retrieve initialization parameters.
- The application initializes the oneVPL JPEG decoder with the following settings:
 - The `PicStruct` field of the `mfxVideoParam` structure set to the correct interlaced type, `MFX_PICSTRUCT_FIELD_TFF` or `MFX_PICSTRUCT_FIELD_BFF`, from the motion JPEG header.
 - Double the `Height` field in the `mfxVideoParam` structure as the value returned by the `MFXVideoDECODE_DecodeHeader()` function describes only the first field. The actual frame surface should contain both fields.
- During decoding, the application sends both fields for decoding in the same `mfxBitstream`. The application should also set `mfxBitstream::DataFlag` to `MFX_BITSTREAM_COMPLETE_FRAME`. oneVPL decodes both fields and combines them into odd and even lines according to oneVPL convention.

By default, the `MFVideoDECODE_DecodeHeader()` function returns the `Rotation` parameter so that after rotation, the pixel at the first row and first column is at the top left. The application can overwrite the default rotation before calling `MFVideoDECODE_Init()`.

The application may specify Huffman and quantization tables during decoder initialization by attaching `mfxExtJPEGQuantTables` and `mfxExtJPEGHuffmanTables` buffers to the `mfxVideoParam` structure. In this case, the decoder ignores tables from bitstream and uses the tables specified by the application. The application can also retrieve these tables by attaching the same buffers to `mfxVideoParam` and calling `MFVideoDECODE_GetVideoParam()` or `MFVideoDECODE_DecodeHeader()` functions.

Multi-view Video Decoding

The oneVPL MVC decoder operates on complete MVC streams that contain all view and temporal configurations. The application can configure the oneVPL decoder to generate a subset at the decoding output. To do this, the application must understand the stream structure and use the stream information to configure the decoder for target views.

The decoder initialization procedure is as follows:

1. The application calls the `MFVideoDECODE_DecodeHeader()` function to obtain the stream structural information. This is done in two steps:
 1. The application calls the `MFVideoDECODE_DecodeHeader()` function with the `mfxExtMVCSeqDesc` structure attached to the `mfxVideoParam` structure. At this point, do not allocate memory for the arrays in the `mfxExtMVCSeqDesc` structure. Set the `View`, `ViewId`, and `OP` pointers to `NULL` and set `NumViewAlloc`, `NumViewIdAlloc`, and `NumOPAlloc` to zero. The function parses the bitstream and returns `mfxStatus::MFX_ERR_NOT_ENOUGH_BUFFER` with the correct values for `NumView`, `NumViewId`, and `NumOP`. This step can be skipped if the application is able to obtain the `NumView`, `NumViewId`, and `NumOP` values from other sources.
 2. The application allocates memory for the `View`, `ViewId`, and `OP` arrays and calls the `MFVideoDECODE_DecodeHeader()` function again. The function returns the MVC structural information in the allocated arrays.
2. The application fills the `mfxExtMVCTargetViews` structure to choose the target views, based on information described in the `mfxExtMVCSeqDesc` structure.
3. The application initializes the oneVPL decoder using the `MFVideoDECODE_Init()` function. The application must attach both the `mfxExtMVCSeqDesc` structure and the `mfxExtMVCTargetViews` structure to the `mfxVideoParam` structure.

In the above steps, do not modify the values of the `mfxExtMVCSeqDesc` structure after the `MFVideoDECODE_DecodeHeader()` function, as the oneVPL decoder uses the values in the structure for internal memory allocation. Once the application configures the oneVPL decoder, the rest of the decoding procedure remains unchanged. As shown in the pseudo code below, the application calls the `MFVideoDECODE_DecodeFrameAsync()` function multiple times to obtain all target views of the current frame picture, one target view at a time. The target view is identified by the `FrameID` field of the `mfxFrameInfo` structure.

```

1 mfxExtBuffer *eb[2];
2 mfxExtMVCSeqDesc seq_desc;
3 mfxVideoParam init_param;
4
5 init_param.ExtParam=(mfxExtBuffer **)&eb;
6 init_param.NumExtParam=1;
7 eb[0]=(mfxExtBuffer *)&seq_desc;
8 MFVideoDECODE_DecodeHeader(session, bitstream, &init_param);
9
10 /* select views to decode */

```

(continues on next page)

(continued from previous page)

```

11 mfxExtMVCTargetViews tv;
12 init_param.NumExtParam=2;
13 eb[1]=(mfxExtBuffer *)&tv;
14
15 /* initialize decoder */
16 MFXVideoDECODE_Init(session, &init_param);
17
18 /* perform decoding */
19 for (;;) {
20     MFXVideoDECODE_DecodeFrameAsync(session, bits, work, &disp, &syncp);
21     disp->FrameInterface->Synchronize(disp, INFINITE); // or MFXVideoCORE_
    ↪ SyncOperation(session, syncp, INFINITE)
22 }
23
24 /* close decoder */
25 MFXVideoDECODE_Close(session);

```

Combined Decode with Multi-channel Video Processing

The oneVPL exposes interface for making decode and video processing operations in one call. Users can specify a number of output processing channels and multiple video filters per each channel. This interface supports only internal memory allocation model and returns array of processed frames through *mfxSurfaceArray* reference object as shown by the example:

```

1 num_channel_par = 2;
2 // first video processing channel with resize
3 vpp_par_array[0]->VPP.Width = 400;
4 vpp_par_array[0]->VPP.Height = 400;
5
6 // second video channel with color conversion filter
7 vpp_par_array[1]->VPP.FourCC = MFX_FOURCC_UYVY;
8
9 sts = MFXVideoDECODE_VPP_Init(session, decode_par, vpp_par_array, num_channel_par);
10
11 sts = MFXVideoDECODE_VPP_DecodeFrameAsync(session, bitstream, NULL, 0, &surf_array_out);
12
13 //surf_array_out layout is
14 do_smth(surf_array_out->Surfaces[0]); //The first channel contains decoded frames.
15 do_smth(surf_array_out->Surfaces[1]); //The second channel contains resized frames after
    ↪ decode.
16 do_smth(surf_array_out->Surfaces[2]); //The third channel contains color converted
    ↪ frames after decode.

```

It's possible that different video processing channels may have different latency:

```

1 //1st call
2 sts = MFXVideoDECODE_VPP_DecodeFrameAsync(session, bitstream, NULL, 0, &surf_array_out);
3 //surf_array_out layout is
4 do_smth(surf_array_out->Surfaces[0]); //decoded frame
5 do_smth(surf_array_out->Surfaces[1]); //resized frame (ChannelId = 1). The first frame
    ↪ from channel with resize available

```

(continues on next page)

(continued from previous page)

```

6 // no output from channel with ADI output since it has one frame delay
7
8 //2nd call
9 sts = MFXVideoDECODE_VPP_DecodeFrameAsync(session, bitstream, NULL, 0, &surf_array_out);
10 //surf_array_out layout is
11 do_smth(surf_array_out->Surfaces[0]); //decoded frame
12 do_smth(surf_array_out->Surfaces[1]); //resized frame (ChannelId = 1)
13 do_smth(surf_array_out->Surfaces[2]); //ADI output (ChannelId = 2). The first frame from
  ↳ADI channel

```

Application can match decoded frame w/ specific VPP channels using `mfxFrameData::TimeStamp`, `:cpp:member:mfxFrameData::FrameOrder` and mfxFrameInfo::ChannelId.`

Application can skip some or all channels including decoding output with help of `skip_channels` and `num_skip_channels` parameters as follows: application fills `skip_channels` array with `ChannelId`'s to disable output of correspondent channels. In that case `:cpp:member:`surf_array_out` would contain only surfaces for the remaining channels. If the decoder's channel and/or impacted VPP channels don't have output frame(s) for the current call (for instance, input bitstream doesn't contain complete frame or deinterlacing/FRC filter have delay) skip_channels parameter is ignored for this channel.`

If application disables all channels the SDK returns NULL as `mfxSurfaceArray`.

If application doesn't need to disable any channels it sets `num_skip_channels` to zero, `skip_channels` is ignored when `num_skip_channels` is zero.

Note: Even if more than one input compressed frame is consumed, the `MFXVideoDECODE_VPP_DecodeFrameAsync()` produces only one decoded frame and correspondent frames from VPP channels.

10.3.5 Encoding Procedures

There are two methods for shared memory allocation and handling in oneVPL: external and internal.

External Memory

The following pseudo code shows the encoding procedure with external memory (legacy mode):

```

1 MFXVideoENCODE_QueryIOSurf(session, &init_param, &request);
2 allocate_pool_of_frame_surfaces(request.NumFrameSuggested);
3 MFXVideoENCODE_Init(session, &init_param);
4 sts=MFX_ERR_MORE_DATA;
5 for (;;) {
6     if (sts==MFX_ERR_MORE_DATA && !end_of_stream()) {
7         find_unlocked_surface_from_the_pool(&surface);
8         fill_content_for_encoding(surface);
9     }
10    surface2=end_of_stream()?NULL:surface;
11    sts=MFXVideoENCODE_EncodeFrameAsync(session,NULL,surface2,bits,&syncp);
12    if (end_of_stream() && sts==MFX_ERR_MORE_DATA) break;
13    // Skipped other error handling
14    if (sts==MFX_ERR_NONE) {

```

(continues on next page)

(continued from previous page)

```

15     MFXVideoCORE_SyncOperation(session, syncp, INFINITE);
16     do_something_with_encoded_bits(bits);
17 }
18 }
19 MFXVideoENCODE_Close(session);
20 free_pool_of_frame_surfaces();

```

Note the following key points about the example:

- The application uses the `MFXVideoENCODE_QueryIOSurf()` function to obtain the number of working frame surfaces required for reordering input frames.
- The application calls the `MFXVideoENCODE_EncodeFrameAsync()` function for the encoding operation. The input frame must be in an unlocked frame surface from the frame surface pool. If the encoding output is not available, the function returns the `mfxStatus::MFX_ERR_MORE_DATA` status code to request additional input frames.
- Upon successful encoding, the `MFXVideoENCODE_EncodeFrameAsync()` function returns `mfxStatus::MFX_ERR_NONE`. At this point, the encoded bitstream is not yet available because the `MFXVideoENCODE_EncodeFrameAsync()` function is asynchronous. The application must use the `MFXVideoCORE_SyncOperation()` function to synchronize the encoding operation before retrieving the encoded bitstream.
- At the end of the stream, the application continuously calls the `MFXVideoENCODE_EncodeFrameAsync()` function with a NULL surface pointer to drain any remaining bitstreams cached within the oneVPL encoder, until the function returns `mfxStatus::MFX_ERR_MORE_DATA`.

Note: It is the application's responsibility to fill pixels outside of the crop window when it is smaller than the frame to be encoded, especially in cases when crops are not aligned to minimum coding block size (16 for AVC and 8 for HEVC and VP9).

Internal Memory

The following pseudo code shows the encoding procedure with internal memory:

```

1 MFXVideoENCODE_Init(session, &init_param);
2 sts=MFX_ERR_MORE_DATA;
3 for (;;) {
4     if (sts==MFX_ERR_MORE_DATA && !end_of_stream()) {
5         MFXMemory_GetSurfaceForEncode(session,&surface);
6         fill_content_for_encoding(surface);
7     }
8     surface2=end_of_stream()?NULL:surface;
9     sts=MFXVideoENCODE_EncodeFrameAsync(session,NULL,surface2,bits,&syncp);
10    if (surface2) surface->FrameInterface->Release(surface2);
11    if (end_of_stream() && sts==MFX_ERR_MORE_DATA) break;
12    // Skipped other error handling
13    if (sts==MFX_ERR_NONE) {
14        MFXVideoCORE_SyncOperation(session, syncp, INFINITE);
15        do_something_with_encoded_bits(bits);
16    }

```

(continues on next page)

(continued from previous page)

```

17 }
18 MFXVideoENCODE_Close(session);

```

There are several key differences in this example, compared to external memory (legacy mode):

- The application does not need to call the *MFXVideoENCODE_QueryIOSurf()* function to obtain the number of working frame surfaces since allocation is done by oneVPL.
- The application calls the *MFXMemory_GetSurfaceForEncode()* function to get a free surface for the subsequent encode operation.
- The application must call the *mfxFrmSurfaceInterface::Release* function to decrement the reference counter of the obtained surface after the call to the *MFXVideoENCODE_EncodeFrameAsync()* function.

Configuration Change

The application changes configuration during encoding by calling the *MFXVideoENCODE_Reset()* function. Depending on the difference in configuration parameters before and after the change, the oneVPL encoder will either continue the current sequence or start a new one. If the encoder starts a new sequence, it completely resets internal state and begins a new sequence with the IDR frame.

The application controls encoder behavior during parameter change by attaching the *mfxFrmEncoderResetOption* structure to the *mfxFrmVideoParam* structure during reset. By using this structure, the application instructs the encoder to start or not start a new sequence after reset. In some cases, the request to continue the current sequence cannot be satisfied and the encoder will fail during reset. To avoid this scenario, the application may query the reset outcome before the actual reset by calling the *MFXVideoENCODE_Query()* function with the *mfxFrmEncoderResetOption* attached to the *mfxFrmVideoParam* structure.

The application uses the following procedure to change encoding configurations:

1. The application retrieves any cached frames in the oneVPL encoder by calling the *MFXVideoENCODE_EncodeFrameAsync()* function with a NULL input frame pointer until the function returns *mfxFrmStatus::MFX_ERR_MORE_DATA*.
2. The application calls the *MFXVideoENCODE_Reset()* function with the new configuration:
 - If the function successfully sets the configuration, the application can continue encoding as usual.
 - If the new configuration requires a new memory allocation, the function returns *mfxFrmStatus::MFX_ERR_INCOMPATIBLE_VIDEO_PARAM*. The application must close the oneVPL encoder and reinitialize the encoding procedure with the new configuration.

External Bitrate Control

The application can make the encoder use the external Bitrate Control (BRC) instead of the native bitrate control. To make the encoder use the external BRC, the application should attach the *mfxFrmExtCodingOption2* structure with *ExtBRC = MFX_CODINGOPTION_ON* and the *mfxFrmExtBRC* callback structure to the *mfxFrmVideoParam* structure during encoder initialization. The **Init**, **Reset**, and **Close** callbacks will be invoked inside their corresponding functions: *MFXVideoENCODE_Init()*, *MFXVideoENCODE_Reset()*, and *MFXVideoENCODE_Close()*. The following figure shows asynchronous encoding flow with external BRC (using *GetFrameCtrl* and *Update*):

Note: *IntAsyncDepth* is the oneVPL max internal asynchronous encoding queue size. It is always less than or equal to *mfxFrmVideoParam::AsyncDepth*.

The following pseudo code shows use of the external BRC:

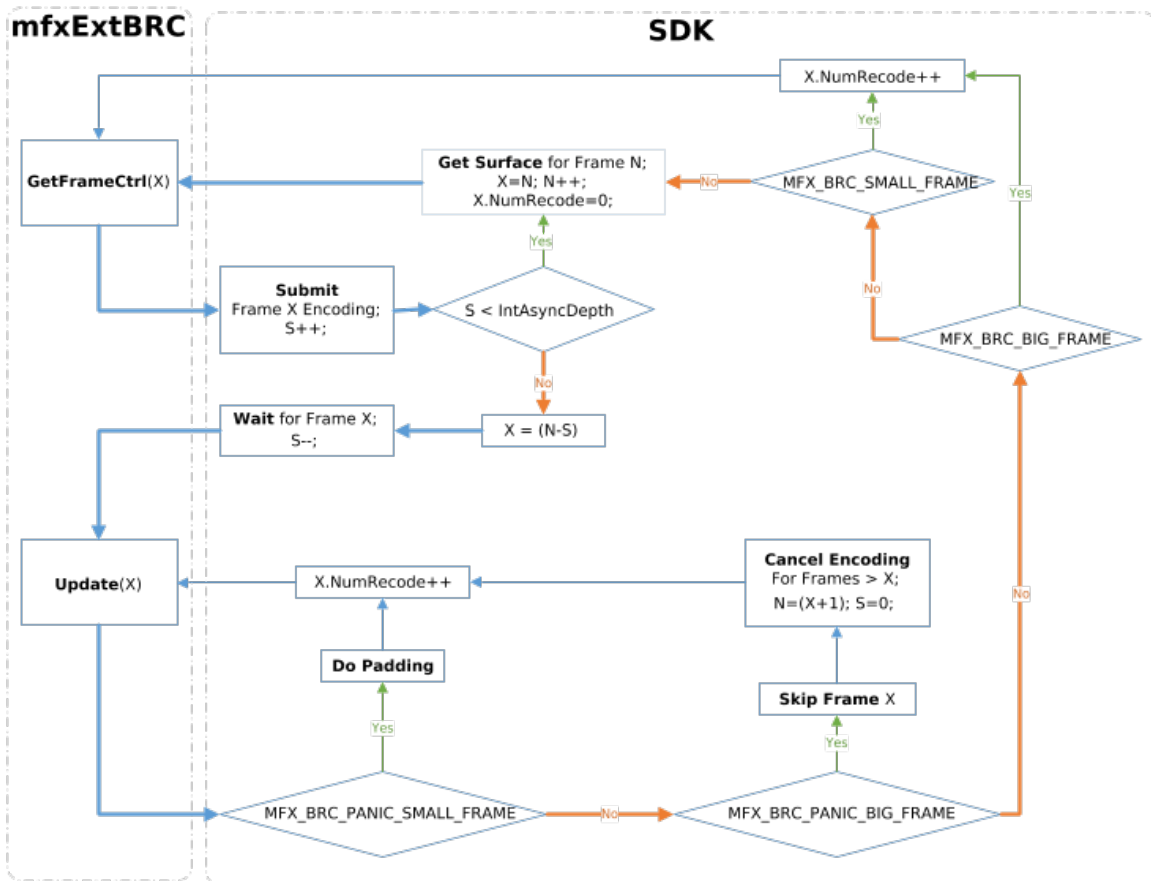

Fig. 4: Asynchronous encoding flow with external BRC

JPEG

The application can use the same encoding procedures for JPEG/motion JPEG encoding, as shown in the following pseudo code:

```

// encoder initialization
MFXVideoENCODE_Init (...);
// single frame/picture encoding
MFXVideoENCODE_EncodeFrameAsync (...);
MFXVideoCORE_SyncOperation(...);
// close down
MFXVideoENCODE_Close(...);

```

The application may specify Huffman and quantization tables during encoder initialization by attaching *mfxExtJPEGQuantTables* and *mfxExtJPEGHuffmanTables* buffers to the *mfxVideoParam* structure. If the application does not define tables, then the oneVPL encoder uses tables recommended in ITU-T* Recommendation T.81. If the application does not define a quantization table it must specify the *mfxInfoMFX::Quality* parameter. In this case, the oneVPL encoder scales the default quantization table according to the specified *mfxInfoMFX::Quality* parameter value.

The application should properly configure chroma sampling format and color format using the *mfxFrameInfo::FourCC* and *mfxFrameInfo::ChromaFormat* fields. For example, to encode a 4:2:2 vertically sampled YCbCr picture, the application should set *mfxFrameInfo::FourCC* to *MFX_FOURCC_YUY2* and *mfxFrameInfo::ChromaFormat* to *MFX_CHROMAFORMAT_YUV422V*. To encode a 4:4:4 sampled RGB picture, the application should set *mfxFrameInfo::FourCC* to *MFX_FOURCC_RGB4* and *mfxFrameInfo::ChromaFormat* to *MFX_CHROMAFORMAT_YUV444*.

The oneVPL encoder supports different sets of chroma sampling and color formats on different platforms. The application must call the *MFXVideoENCODE_Query()* function to check if the required color format is supported on a given platform and then initialize the encoder with proper values of *mfxFrameInfo::FourCC* and *mfxFrameInfo::ChromaFormat*.

The application should not define the number of scans and number of components. These numbers are derived by the oneVPL encoder from the *mfxInfoMFX::Interleaved* flag and from chroma type. If interleaved coding is specified, then one scan is encoded that contains all image components. Otherwise, the number of scans is equal to number of components. The encoder uses the following component IDs: “1” for luma (Y), “2” for chroma Cb (U), and “3” for chroma Cr (V).

The application should allocate a buffer that is big enough to hold the encoded picture. A rough upper limit may be calculated using the following equation where **Width** and **Height** are width and height of the picture in pixel and **BytesPerPx** is the number of bytes for one pixel:

$$\text{BufferSizeInKB} = 4 + (\text{Width} * \text{Height} * \text{BytesPerPx} + 1023) / 1024;$$

The equation equals 1 for a monochrome picture, 1.5 for NV12 and YV12 color formats, 2 for YUY2 color format, and 3 for RGB32 color format (alpha channel is not encoded).

Multi-view Video Encoding

Similar to the decoding and video processing initialization procedures, the application attaches the *mfExtMVCSeqDesc* structure to the *mfVideoParam* structure for encoding initialization. The *mfExtMVCSeqDesc* structure configures the oneVPL MVC encoder to work in three modes:

- **Default dependency mode:** The application specifies *mfExtMVCSeqDesc::NumView* and all other fields to zero. The oneVPL encoder creates a single operation point with all views (view identifier 0 : NumView-1) as target views. The first view (view identifier 0) is the base view. Other views depend on the base view.
- **Explicit dependency mode:** The application specifies *mfExtMVCSeqDesc::NumView* and the view dependency array, and sets all other fields to zero. The oneVPL encoder creates a single operation point with all views (view identifier View[0 : NumView-1].ViewId) as target views. The first view (view identifier View[0].ViewId) is the base view. View dependencies are defined as *mfMVCViewDependency* structures.
- **Complete mode:** The application fully specifies the views and their dependencies. The oneVPL encoder generates a bitstream with corresponding stream structures.

During encoding, the oneVPL encoding function *MFVideoENCODE_EncodeFrameAsync()* accumulates input frames until encoding of a picture is possible. The function returns *mfStatus::MFX_ERR_MORE_DATA* for more data at input or *mfStatus::MFX_ERR_NONE* if it successfully accumulated enough data for encoding a picture. The generated bitstream contains the complete picture (multiple views). The application can change this behavior and instruct the encoder to output each view in a separate bitstream buffer. To do so, the application must turn on the *mfExtCodingOption::ViewOutput* flag. In this case, the encoder returns *mfStatus::MFX_ERR_MORE_BITSTREAM* if it needs more bitstream buffers at output and *mfStatus::MFX_ERR_NONE* when processing of the picture (multiple views) has been finished. It is recommended that the application provide a new input frame each time the oneVPL encoder requests a new bitstream buffer. The application must submit view data for encoding in the order they are described in the *mfExtMVCSeqDesc* structure. Particular view data can be submitted for encoding only when all views that it depends upon have already been submitted.

The following pseudo code shows the encoding procedure:

```

1  mfExtBuffer *eb;
2  mfExtMVCSeqDesc seq_desc;
3  mfVideoParam init_param;
4
5  init_param.ExtParam=(mfExtBuffer **)&eb;
6  init_param.NumExtParam=1;
7  eb=(mfExtBuffer *)&seq_desc;
8
9  /* init encoder */
10 MFVideoENCODE_Init(session, &init_param);
11
12 /* perform encoding */
13 for (;;) {
14     MFVideoENCODE_EncodeFrameAsync(session, NULL, surface2, bits,
15                                     &syncp);
16     MFVideoCORE_SyncOperation(session, syncp, INFINITE);
17 }
18
19 /* close encoder */
20 MFVideoENCODE_Close(session);
21 }

```

10.3.6 Video Processing Procedures

The following pseudo code shows the video processing procedure:

```

1 MFXVideoVPP_QueryIOSurf(session, &init_param, response);
2 allocate_pool_of_surfaces(in_pool, response[0].NumFrameSuggested);
3 allocate_pool_of_surfaces(out_pool, response[1].NumFrameSuggested);
4 MFXVideoVPP_Init(session, &init_param);
5 mfxFrameSurface1 *in=find_unlocked_surface_and_fill_content(in_pool);
6 mfxFrameSurface1 *out=find_unlocked_surface_from_the_pool(out_pool);
7 for (;;) {
8     sts=MFXVideoVPP_RunFrameVPPAsync(session,in,out,NULL,&syncp);
9     if (sts==MFX_ERR_MORE_SURFACE || sts==MFX_ERR_NONE) {
10        MFXVideoCORE_SyncOperation(session, syncp, INFINITE);
11        process_output_frame(out);
12        out=find_unlocked_surface_from_the_pool(out_pool);
13    }
14    if (sts==MFX_ERR_MORE_DATA && in==NULL)
15        break;
16    if (sts==MFX_ERR_NONE || sts==MFX_ERR_MORE_DATA) {
17        in=find_unlocked_surface_from_the_pool(in_pool);
18        fill_content_for_video_processing(in);
19        if (end_of_stream())
20            in=NULL;
21    }
22 }
23 MFXVideoVPP_Close(session);
24 free_pool_of_surfaces(in_pool);
25 free_pool_of_surfaces(out_pool);

```

Note the following key points about the example:

- The application uses the *MFXVideoVPP_QueryIOSurf()* function to obtain the number of frame surfaces needed for input and output. The application must allocate two frame surface pools: one for the input and one for the output.
- The video processing function *MFXVideoVPP_RunFrameVPPAsync()* is asynchronous. The application must use the *MFXVideoCORE_SyncOperation()* function to synchronize in order to make the output result ready.
- The body of the video processing procedure covers the following three scenarios:
 - If the number of frames consumed at input is equal to the number of frames generated at output, *VPP* returns *mfxStatus::MFX_ERR_NONE* when an output is ready. The application must process the output frame after synchronization, as the *MFXVideoVPP_RunFrameVPPAsync()* function is asynchronous. The application must provide a NULL input at the end of the sequence to drain any remaining frames.
 - If the number of frames consumed at input is more than the number of frames generated at output, *VPP* returns *mfxStatus::MFX_ERR_MORE_DATA* for additional input until an output is ready. When the output is ready, *VPP* returns *mfxStatus::MFX_ERR_NONE*. The application must process the output frame after synchronization and provide a NULL input at the end of the sequence to drain any remaining frames.
 - If the number of frames consumed at input is less than the number of frames generated at output, *VPP* returns either *mfxStatus::MFX_ERR_MORE_SURFACE* (when more than one output is ready), or *mfxStatus::MFX_ERR_NONE* (when one output is ready and *VPP* expects new input). In both cases, the application must process the output frame after synchronization and provide a NULL input at the end of the sequence to drain any remaining frames.

Configuration

oneVPL configures the video processing pipeline operation based on the difference between the input and output formats, specified in the *mfxVideoParam* structure. The following list shows several examples:

- When the input color format is *YUY2* and the output color format is *NV12*, oneVPL enables color conversion from YUY2 to NV12.
- When the input is interleaved and the output is progressive, oneVPL enables deinterlacing.
- When the input is single field and the output is interlaced or progressive, oneVPL enables field weaving, optionally with deinterlacing.
- When the input is interlaced and the output is single field, oneVPL enables field splitting.

In addition to specifying the input and output formats, the application can provide hints to fine-tune the video processing pipeline operation. The application can disable filters in the pipeline by using the *mfxExtVPPDoNotUse* structure, enable filters by using the *mfxExtVPPDoUse* structure, and configure filters by using dedicated configuration structures. See the *Configurable VPP Filters table* for a complete list of configurable video processing filters, their IDs, and configuration structures. See the *ExtendedBufferID enumerator* for more details.

oneVPL ensures that all filters necessary to convert the input format to the output format are included in the pipeline. oneVPL may skip some optional filters even if they are explicitly requested by the application, for example due to limitations of the underlying hardware. To notify the application about skipped optional filters, oneVPL returns the *mfxStatus::MFX_WRN_FILTER_SKIPPED* warning. The application can retrieve the list of active filters by attaching the *mfxExtVPPDoUse* structure to the *mfxVideoParam* structure and calling the *MFXVideoVPP_GetVideoParam()* function. The application must allocate enough memory for the filter list.

See the *Configurable VPP Filters table* for a full list of configurable filters.

Table 6: Configurable VPP Filters

Filter ID	Configuration Structure
<i>MFX_EXTBUFF_VPP_DENOISE2</i>	<i>mfxExtVPPDenoise2</i>
<i>MFX_EXTBUFF_VPP_MCTF</i>	<i>mfxExtVppMctf</i>
<i>MFX_EXTBUFF_VPP_DETAIL</i>	<i>mfxExtVPPDetail</i>

<i>MFX_EXTBUFF_VPP_FIELD_PROCESSING</i>	<i>mfxExtVPPFieldProcessing</i>
<i>MFX_EXTBUFF_VPP_3DLUT</i>	<i>mfxExtVPP3DLut</i>

The following example shows video processing configuration:

```

1  /* enable image stabilization filter with default settings */
2  mfxExtVPPDoUse du;
3  mfxU32 al=MFX_EXTBUFF_VPP_IMAGE_STABILIZATION;
4
5  du.Header.BufferId=MFX_EXTBUFF_VPP_DOUSE;
6  du.Header.BufferSz=sizeof(mfxExtVPPDoUse);
7  du.NumAlg=1;
8  du.AlgList=&al;
9
10 /* configure the mfxVideoParam structure */
11 mfxVideoParam conf;
12 mfxExtBuffer *eb=(mfxExtBuffer *)&du;
13

```

(continues on next page)

(continued from previous page)

```

14 memset(&conf, 0, sizeof(conf));
15 conf.IOPattern=MFX_IOPATTERN_IN_SYSTEM_MEMORY | MFX_IOPATTERN_OUT_SYSTEM_MEMORY;
16 conf.NumExtParam=1;
17 conf.ExtParam=&eb;
18
19 conf.vpp.In.FourCC=MFX_FOURCC_YV12;
20 conf.vpp.Out.FourCC=MFX_FOURCC_NV12;
21 conf.vpp.In.Width=conf.vpp.Out.Width=1920;
22 conf.vpp.In.Height=conf.vpp.Out.Height=1088;
23
24 /* video processing initialization */
25 MFXVideoVPP_Init(session, &conf);

```

Region of Interest

During video processing operations, the application can specify a region of interest for each frame as shown in the following figure:

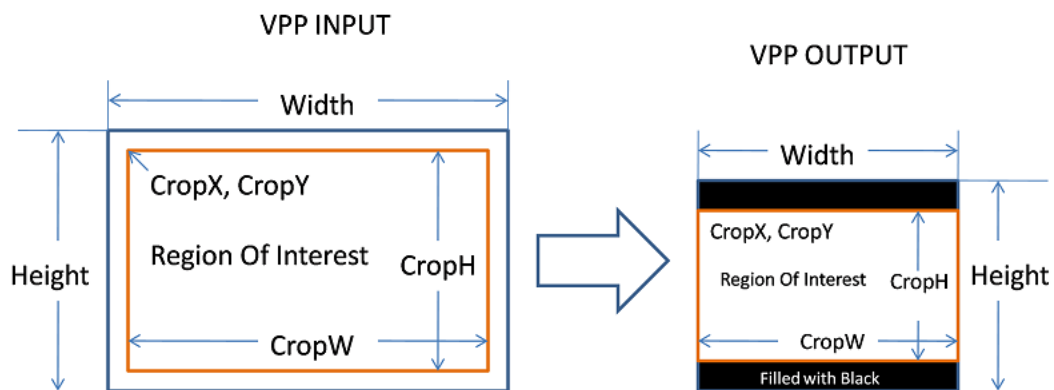

Fig. 5: VPP region of interest operation

Specifying a region of interest guides the resizing function to achieve special effects, such as resizing from 16:9 to 4:3, while keeping the aspect ratio intact. Use the CropX, CropY, CropW, and CropH parameters in the *mfxVideoParam* structure to specify a region of interest.

The *VPP Region of Interest Operations table* shows examples of VPP operations applied to a region of interest.

Table 7: VPP Region of Interest Operations

Operation	VPP Input Width X Height	VPP Input CropX, CropY, CropW, CropH	VPP Output Width X Height	VPP Output CropX, CropY, CropW, CropH
Cropping	720 x 480	16, 16, 688, 448	720 x 480	16, 16, 688, 448
Resizing	720 x 480	0, 0, 720, 480	1440 x 960	0, 0, 1440, 960
Horizontal stretching	720 x 480	0, 0, 720, 480	640 x 480	0, 0, 640, 480
16:9 4:3 with letter boxing at the top and bottom	1920 x 1088	0, 0, 1920, 1088	720 x 480	0, 36, 720, 408
4:3 16:9 with pillar boxing at the left and right	720 x 480	0, 0, 720, 480	1920 x 1088	144, 0, 1632, 1088

Multi-view Video Processing

oneVPL video processing supports processing multiple views. For video processing initialization, the application needs to attach the `mfxExtMVCSeqDesc` structure to the `mfxVideoParam` structure and call the `MFXVideoVPP_Init()` function. The function saves the view identifiers. During video processing, oneVPL processes each view individually. oneVPL refers to the `FrameID` field of the `mfxFrameInfo` structure to configure each view according to its processing pipeline. If the video processing source frame is not the output from the oneVPL MVC decoder, then the application needs to fill the `FrameID` field before calling the `MFXVideoVPP_RunFrameVPPAsync()` function. This is shown in the following pseudo code:

```

1 mfxExtBuffer *eb;
2 mfxExtMVCSeqDesc seq_desc;
3 mfxVideoParam init_param;
4
5 init_param.ExtParam = &eb;
6 init_param.NumExtParam=1;
7 eb=(mfxExtBuffer *)&seq_desc;
8
9 /* init VPP */
10 MFXVideoVPP_Init(session, &init_param);
11
12 /* perform processing */
13 for (;;) {
14     MFXVideoVPP_RunFrameVPPAsync(session,in,out,NULL,&syncp);
15     MFXVideoCORE_SyncOperation(session,syncp,INFINITE);
16 }
17
18 /* close VPP */
19 MFXVideoVPP_Close(session);

```

Video Processing 3DLUT

oneVPL video processing supports 3DLUT with Intel HW specific memory layout. The following pseudo code shows how to create a `MFX_3DLUT_MEMORY_LAYOUT_INTEL_65LUT` 3DLUT surface.

```

1  VADisplay va_dpy = 0;
2  VASurfaceID surface_id = 0;
3
4  vaInitialize(va_dpy, NULL, NULL);
5
6  // MFX_3DLUT_MEMORY_LAYOUT_INTEL_65LUT indicate 65*65*128*8bytes.
7  mfxU32 seg_size = 65, mul_size = 128;
8  mfxMemId memId = 0;
9
10 // create 3DLUT surface (MFX_3DLUT_MEMORY_LAYOUT_INTEL_65LUT)
11 VASurfaceAttrib surface_attrib = {};
12 surface_attrib.type = VASurfaceAttribPixelFormat;
13 surface_attrib.flags = VA_SURFACE_ATTRIB_SETTABLE;
14 surface_attrib.value.type = VAGenericValueTypeInteger;
15 surface_attrib.value.value.i = VA_FOURCC_RGBA;
16
17 vaCreateSurfaces(va_dpy,
18                 VA_RT_FORMAT_RGB32, // 4 bytes
19                 seg_size * mul_size, // 65*128
20                 seg_size * 2, // 65*2
21                 &surface_id,
22                 1,
23                 &surface_attrib,
24                 1);
25
26 *((VASurfaceID*)memId) = surface_id;
27
28 // configure 3DLUT parameters
29 mfxExtVPP3DLut lut3DConfig;
30 memset(&lut3DConfig, 0, sizeof(lut3DConfig));
31 lut3DConfig.Header.BufferId = MFX_EXTBUFF_VPP_3DLUT;
32 lut3DConfig.Header.BufferSz = sizeof(mfxExtVPP3DLut);
33 lut3DConfig.ChannelMapping = MFX_3DLUT_CHANNEL_MAPPING_RGB_RGB;
34 lut3DConfig.BufferType = MFX_RESOURCE_VA_SURFACE;
35 lut3DConfig.VideoBuffer.DataType = MFX_DATA_TYPE_U16;
36 lut3DConfig.VideoBuffer.MemLayout = MFX_3DLUT_MEMORY_LAYOUT_INTEL_65LUT;
37 lut3DConfig.VideoBuffer.MemId = memId;
38
39 // release 3DLUT surface
40 vaDestroySurfaces(va_dpy, &surface_id, 1);

```

The following pseudo code shows how to create a system memory `mfx3DLutSystemBuffer` 3DLUT surface.

```

1 // 64 size 3DLUT
2 mfxU8 dataR[64], dataG[64], dataB[64];
3 mfxChannel channelR, channelG, channelB;
4 channelR.DataType = MFX_DATA_TYPE_U8;
5 channelR.Size = 64;
6 channelR.Data = dataR;

```

(continues on next page)

(continued from previous page)

```

7 channelG.DataType = MFX_DATA_TYPE_U8;
8 channelG.Size = 64;
9 channelG.Data = dataG;
10 channelB.DataType = MFX_DATA_TYPE_U8;
11 channelB.Size = 64;
12 channelB.Data = dataB;
13
14 // configure 3DLUT parameters
15 mfxExtVPP3DLut lut3DConfig;
16 memset(&lut3DConfig, 0, sizeof(lut3DConfig));
17 lut3DConfig.Header.BufferId      = MFX_EXTBUFF_VPP_3DLUT;
18 lut3DConfig.Header.BufferSz     = sizeof(mfxExtVPP3DLut);
19 lut3DConfig.ChannelMapping      = MFX_3DLUT_CHANNEL_MAPPING_RGB_RGB;
20 lut3DConfig.BufferType          = MFX_RESOURCE_SYSTEM_SURFACE;
21 lut3DConfig.SystemBuffer.Channel[0] = channelR;
22 lut3DConfig.SystemBuffer.Channel[1] = channelG;
23 lut3DConfig.SystemBuffer.Channel[2] = channelB;

```

HDR Tone Mapping

oneVPL video processing supports HDR Tone Mapping with Intel HW. The following pseudo code shows how to perform HDR Tone Mapping.

The following pseudo code shows HDR to SDR.

```

1 // HDR to SDR (e.g P010 HDR signal -> NV12 SDR signal) in transcoding pipeline
2 // Attach input external buffers as the below for HDR input. SDR is by default, hence no
3 // extra output external buffer.
4 // The input Video Signal Information
5 mfxExtVideoSignalInfo inSignalInfo = {};
6 inSignalInfo.Header.BufferId      = MFX_EXTBUFF_VIDEO_SIGNAL_INFO_IN;
7 inSignalInfo.Header.BufferSz     = sizeof(mfxExtVideoSignalInfo);
8 inSignalInfo.VideoFullRange      = 0; // Limited range P010
9 inSignalInfo.ColourPrimaries     = 9; // BT.2020
10 inSignalInfo.TransferCharacteristics = 16; // ST2084
11
12 // The content Light Level Information
13 mfxExtContentLightLevelInfo inContentLight = {};
14 inContentLight.Header.BufferId    = MFX_EXTBUFF_CONTENT_LIGHT_LEVEL_INFO;
15 inContentLight.Header.BufferSz   = sizeof(mfxExtContentLightLevelInfo);
16 inContentLight.MaxContentLightLevel = 4000; // nits
17 inContentLight.MaxPicAverageLightLevel = 1000; // nits
18
19 // The mastering display colour volume
20 mfxExtMasteringDisplayColourVolume inColourVolume = {};
21 inColourVolume.Header.BufferId = MFX_EXTBUFF_MASTERING_DISPLAY_COLOUR_VOLUME_IN;
22 inColourVolume.Header.BufferSz = sizeof(mfxExtMasteringDisplayColourVolume);
23 // Based on the needs, Please set DisplayPrimaryX/Y[3], WhitePointX/Y, and
24 // ↪ MaxDisplayMasteringLuminance,
25 // ↪ MinDisplayMasteringLuminance

```

37 // Based on the needs, Please set DisplayPrimaryX/Y[3], WhitePointX/Y, and
38 ↪ MaxDisplayMasteringLuminance,
39 // MinDisplayMasteringLuminance
40
41 mfxExtBuffer *ExtBuffer[5];
42 ExtBuffer[0] = (mfxExtBuffer *)&inSignalInfo;
43 ExtBuffer[1] = (mfxExtBuffer *)&inContentLight;
44 ExtBuffer[2] = (mfxExtBuffer *)&inColourVolume;
45 ExtBuffer[3] = (mfxExtBuffer *)&outSignalInfo;
46 ExtBuffer[4] = (mfxExtBuffer *)&outColourVolume;
47
48 mfxSession session = (mfxSession)0;
49 mfxVideoParam VPPParams = {};
50 VPPParams.NumExtParam = 5;
51 VPPParams.ExtParam = (mfxExtBuffer **) &ExtBuffer[0];
52 MFVideoVPP_Init(session, &VPPParams);

```

Camera RAW acceleration

oneVPL supports camera raw format processing with Intel HW. The following pseudo code shows how to perform camera raw hardware acceleration. For pipeline processing initialization, the application needs to attach the camera structures to the *mfXVideoParam* structure and call the *MFXVideoVPP_Init()* function.

The following pseudo code shows camera raw processing.

```

1  #ifdef ONEVPL_EXPERIMENTAL
2  // Camera Raw Format
3  mfxExtCamPipeControl pipeControl = {};
4  pipeControl.Header.BufferId      = MFX_EXTBUF_CAM_PIPECONTROL;
5  pipeControl.Header.BufferSz      = sizeof(mfxExtCamPipeControl);
6  pipeControl.RawFormat            = (mfxU16)MFX_CAM_BAYER_BGGR;
7
8  // Black level correction
9  mfxExtCamBlackLevelCorrection blackLevelCorrection = {};
10 blackLevelCorrection.Header.BufferId = MFX_EXTBUF_CAM_BLACK_LEVEL_
    ↳CORRECTION;
11 blackLevelCorrection.Header.BufferSz =
    ↳sizeof(mfxExtCamBlackLevelCorrection);
12 mfxU16 black_level_B = 16, black_level_G0 = 16, black_level_G1 = 16, black_level_R = 16;
13 // Initialize the value for black level B, G0, G1, R as needed
14 blackLevelCorrection.B = black_level_B;
15 blackLevelCorrection.G0 = black_level_G0;
16 blackLevelCorrection.G1 = black_level_G1;
17 blackLevelCorrection.R = black_level_R;
18
19 mfxExtBuffer *ExtBufferIn[2];
20 ExtBufferIn[0] = (mfxExtBuffer *)&pipeControl;
21 ExtBufferIn[1] = (mfxExtBuffer *)&blackLevelCorrection;
22
23 mfxSession session = (mfxSession)0;
24 mfxVideoParam VPPParams = {};
25 VPPParams.NumExtParam = 2;
26 VPPParams.ExtParam = (mfxExtBuffer **) &ExtBufferIn[0];
27 MFXVideoVPP_Init(session, &VPPParams);
28 #endif

```

10.3.7 Transcoding Procedures

The application can use oneVPL encoding, decoding, and video processing functions together for transcoding operations. This section describes the key aspects of connecting two or more oneVPL functions together.

Asynchronous Pipeline

The application passes the output of an upstream oneVPL function to the input of the downstream oneVPL function to construct an asynchronous pipeline. Pipeline construction is done at runtime and can be dynamically changed, as shown in the following example:

```

1 mfxSyncPoint sp_d, sp_e;
2 MFXVideoDECODE_DecodeFrameAsync(session,bs,work,&vin, &sp_d);
3 if (going_through_vpp) {
4     MFXVideoVPP_RunFrameVPPAsync(session,vin,vout, NULL, &sp_d);
5     MFXVideoENCODE_EncodeFrameAsync(session,NULL,vout,bits2,&sp_e);
6 } else {
7     MFXVideoENCODE_EncodeFrameAsync(session,NULL,vin,bits2,&sp_e);
8 }
9 MFXVideoCORE_SyncOperation(session,sp_e,INFINITE);

```

oneVPL simplifies the requirements for asynchronous pipeline synchronization. The application only needs to synchronize after the last oneVPL function. Explicit synchronization of intermediate results is not required and may slow performance.

oneVPL tracks dynamic pipeline construction and verifies dependency on input and output parameters to ensure the execution order of the pipeline function. In the previous example, oneVPL will ensure `MFXVideoENCODE_EncodeFrameAsync()` does not begin its operation until `MFXVideoDECODE_DecodeFrameAsync()` or `MFXVideoVPP_RunFrameVPPAsync()` has finished.

During the execution of an asynchronous pipeline, the application must consider the input data as “in use” and must not change it until the execution has completed. The application must also consider output data unavailable until the execution has finished. In addition, for encoders, the application must consider extended and payload buffers as “in use” while the input surface is locked.

oneVPL checks dependencies by comparing the input and output parameters of each oneVPL function in the pipeline. Do not modify the contents of input and output parameters before the previous asynchronous operation finishes. Doing so will break the dependency check and can result in undefined behavior. An exception occurs when the input and output parameters are structures, in which case overwriting fields in the structures is allowed.

Note: The dependency check works on the pointers to the structures only.

There are two exceptions with respect to intermediate synchronization:

- If the input is from any asynchronous operation, the application must synchronize any input before calling the oneVPL `MFXVideoDECODE_DecodeFrameAsync()` function.
- When the application calls an asynchronous function to generate an output surface in video memory and passes that surface to a non-oneVPL component, it must explicitly synchronize the operation before passing the surface to the non-oneVPL component.

Surface Pool Allocation

When connecting API function **A** to API function **B**, the application must take into account the requirements of both functions to calculate the number of frame surfaces in the surface pool. Typically, the application can use the formula $\mathbf{Na} + \mathbf{Nb}$, where \mathbf{Na} is the frame surface requirements for oneVPL function **A** output, and \mathbf{Nb} is the frame surface requirements for oneVPL function **B** input.

For performance considerations, the application must submit multiple operations and delay synchronization as much as possible, which gives oneVPL flexibility to organize internal pipelining. For example, compare the following two operation sequences, where the first sequence is the recommended order:

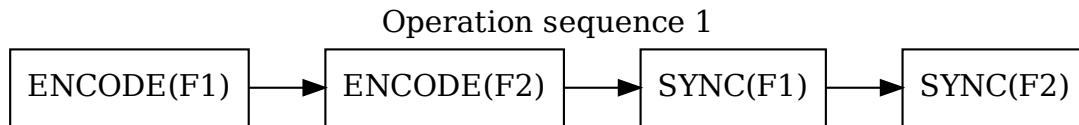

Fig. 6: Recommended operation sequence

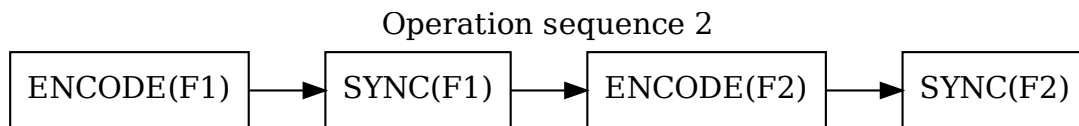

Fig. 7: Operation sequence - not recommended

In this example, the surface pool needs additional surfaces to take into account multiple asynchronous operations before synchronization. The application can use the `mfXVideoParam::AsyncDepth` field to inform a oneVPL function of the number of asynchronous operations the application plans to perform before synchronization. The corresponding oneVPL `QueryIOSurf` function will reflect this number in the `mfXFrameAllocRequest::NumFrameSuggested` value. The following example shows a way of calculating the surface needs based on `mfXFrameAllocRequest::NumFrameSuggested` values:

```

1 mfxVideoParam init_param_v, init_param_e;
2 mfxFrameAllocRequest response_v[2], response_e;
3
4 // Desired depth
5 mfxU16 async_depth=4;
6
7 init_param_v.AsyncDepth=async_depth;
8 MFVideoVPP_QueryIOSurf(session, &init_param_v, response_v);
9 init_param_e.AsyncDepth=async_depth;
10 MFVideoENCODE_QueryIOSurf(session, &init_param_e, &response_e);
11 mfxU32 num_surfaces = response_v[1].NumFrameSuggested
  
```

(continues on next page)

(continued from previous page)

```

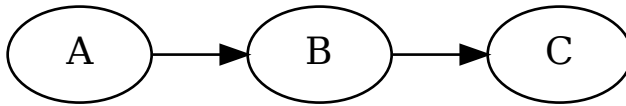

12     + response_e.NumFrameSuggested
13     - async_depth; /* double counted in ENCODE & VPP */
14
15 allocate_surfaces(num_surfaces);

```

Pipeline Error Reporting

During asynchronous pipeline construction, each pipeline stage function will return a synchronization point (sync point). These synchronization points are useful in tracking errors during the asynchronous pipeline operation.

For example, assume the following pipeline:

The application synchronizes on sync point **C**. If the error occurs in function **C**, then the synchronization returns the exact error code. If the error occurs before function **C**, then the synchronization returns `mfxfStatus::MFX_ERR_ABORTED`. The application can then try to synchronize on sync point **B**. Similarly, if the error occurs in function **B**, the synchronization returns the exact error code, or else `mfxfStatus:: MFX_ERR_ABORTED`. The same logic applies if the error occurs in function **A**.

10.3.8 Hardware Acceleration

oneVPL provides a new model for working with hardware acceleration while continuing to support hardware acceleration in legacy mode.

New Model to Work with Hardware Acceleration

oneVPL API version 2.0 introduces a new memory model: internal allocation where oneVPL is responsible for video memory allocation. In this mode, an application is not dependent on a low-level video framework API, such as DirectX* or the VA API, and does not need to create and set corresponding low-level oneVPL primitives such as `ID3D11Device` or `VADisplay`. Instead, oneVPL creates all required objects to work with hardware acceleration and video surfaces internally. An application can get access to these objects using `MFXVideoCORE_GetHandle()` or with help of the `mfxfFrameSurfaceInterface` interface.

This approach simplifies the oneVPL initialization, making calls to the `MFXVideoENCODE_QueryIOSurf()`, `MFXVideoDECODE_QueryIOSurf()`, or `MFXVideoVPP_QueryIOSurf()` functions optional. See *Internal Memory Management*.

Note: Applications can set device handle before session creation through `MFXSetConfigFilterProperty()` like shown in the code below:

```

1 mfxLoader loader = MFXLoad();
2 mfxConfig config1 = MFXCreateConfig(loader);
3 mfxConfig config2 = MFXCreateConfig(loader);
4 mfxSession session;
5
6 mfxVariant HandleType;
7 HandleType.Type = MFX_VARIANT_TYPE_U32;
8 HandleType.Data.U32 = MFX_HANDLE_VA_DISPLAY;
9 MFXSetConfigFilterProperty(config1, (mfxU8*)"mfxHandleType", HandleType);
10
11 mfxVariant DisplayHandle;
12 DisplayHandle.Type = MFX_VARIANT_TYPE_PTR;
13 HandleType.Data.Ptr = vaDisplay;
14 MFXSetConfigFilterProperty(config2, (mfxU8*)"mfxHDL", DisplayHandle);
15
16 MFXCreateSession(loader, 0, &session);

```

Work with Hardware Acceleration in Legacy Mode

Work with Multiple Media Devices

If your system has multiple graphics adapters, you may need hints on which adapter is better suited to process a particular workload. The legacy mode of oneVPL provides a helper API to select the most suitable adapter for your workload based on the provided workload description. The following example shows workload initialization on a discrete adapter:

```

1 mfxU32 num_adapters_available;
2 mfxIMPL impl;
3
4 // Query number of graphics adapters available on system
5 mfxStatus sts = MFXQueryAdaptersNumber(&num_adapters_available);
6 MSDK_CHECK_STATUS(sts, "MFXQueryAdaptersNumber failed");
7
8 // Allocate memory for response
9 std::vector<mfxAdapterInfo> displays_data(num_adapters_available);
10 mfxAdaptersInfo adapters = { displays_data.data(), mfxU32(displays_data.size()), 0u, {0} };
11
12 // Query information about all adapters (mind that first parameter is NULL)
13 sts = MFXQueryAdapters(nullptr, &adapters);
14 MSDK_CHECK_STATUS(sts, "MFXQueryAdapters failed");
15
16 // Find dGfx adapter in list of adapters
17 auto idx_d = std::find_if(adapters.Adapters, adapters.Adapters + adapters.NumActual,
18 [] (const mfxAdapterInfo info)
19 {
20     return info.Platform.MediaAdapterType == mfxMediaAdapterType::MFX_MEDIA_DISCRETE;
21 });
22
23 // No dGfx in list
24 if (idx_d == adapters.Adapters + adapters.NumActual)
25 {

```

(continues on next page)

(continued from previous page)

```

26     printf("Warning: No dGfx detected on machine\n");
27     return -1;
28 }
29
30 mfxU32 idx = static_cast<mfxU32>(std::distance(adapters.Adapters, idx_d));
31
32 // Choose correct implementation for discrete adapter
33 switch (adapters.Adapters[idx].Number)
34 {
35 case 0:
36     impl = MFX_IMPL_HARDWARE;
37     break;
38 case 1:
39     impl = MFX_IMPL_HARDWARE2;
40     break;
41 case 2:
42     impl = MFX_IMPL_HARDWARE3;
43     break;
44 case 3:
45     impl = MFX_IMPL_HARDWARE4;
46     break;
47
48 default:
49     // Try searching on all display adapters
50     impl = MFX_IMPL_HARDWARE_ANY;
51     break;
52 }
53 printf("Chosen implementation: %d\n", impl);
54 // Initialize mfxSession in regular way with obtained implementation.

```

The example shows that after obtaining the adapter list with `MFXQueryAdapters()`, further initialization of `mfxSession` is performed in the regular way. The specific adapter is selected using the `MFX_IMPL_HARDWARE`, `MFX_IMPL_HARDWARE2`, `MFX_IMPL_HARDWARE3`, or `MFX_IMPL_HARDWARE4` values of `mfxIMPL`.

The following example shows the use of `MFXQueryAdapters()` for querying the most suitable adapter for a particular encode workload:

```

1 mfxU32 num_adapters_available;
2 mfxIMPL impl;
3 mfxVideoParam Encode_mfxVideoParam;
4
5 // Query number of graphics adapters available on system
6 mfxStatus sts = MFXQueryAdaptersNumber(&num_adapters_available);
7 MSDK_CHECK_STATUS(sts, "MFXQueryAdaptersNumber failed");
8
9 // Allocate memory for response
10 std::vector<mfxAdapterInfo> displays_data(num_adapters_available);
11 mfxAdaptersInfo adapters = { displays_data.data(), mfxU32(displays_data.size()), 0u, {0} };
12
13 // Fill description of Encode workload
14 mfxComponentInfo interface_request = { MFX_COMPONENT_ENCODE, Encode_mfxVideoParam, {0} };
15

```

(continues on next page)

(continued from previous page)

```

16 // Query information about suitable adapters for Encode workload described by Encode_
    ↪ mfxVideoParam
17 sts = MFXQueryAdapters(&interface_request, &adapters);
18
19 if (sts == MFX_ERR_NOT_FOUND)
20 {
21     printf("Error: No adapters on machine capable to process desired workload\n");
22     return -1;
23 }
24
25 MSDK_CHECK_STATUS(sts, "MFXQueryAdapters failed");
26
27 // Choose correct implementation for discrete adapter. Mind usage of index 0, this is_
    ↪ best suitable adapter from MSDK perspective
28 switch (adapters.Adapters[0].Number)
29 {
30 case 0:
31     impl = MFX_IMPL_HARDWARE;
32     break;
33 case 1:
34     impl = MFX_IMPL_HARDWARE2;
35     break;
36 case 2:
37     impl = MFX_IMPL_HARDWARE3;
38     break;
39 case 3:
40     impl = MFX_IMPL_HARDWARE4;
41     break;
42
43 default:
44     // Try searching on all display adapters
45     impl = MFX_IMPL_HARDWARE_ANY;
46     break;
47 }
48
49 printf("Chosen implementation: %d\n", impl);
50
51 // Initialize mfxSession in regular way with obtained implementation

```

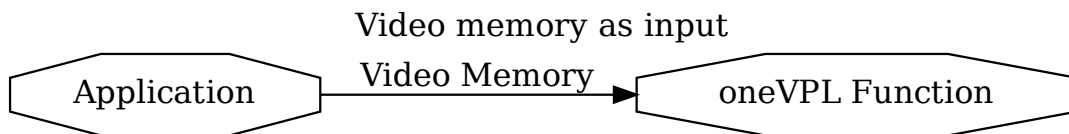

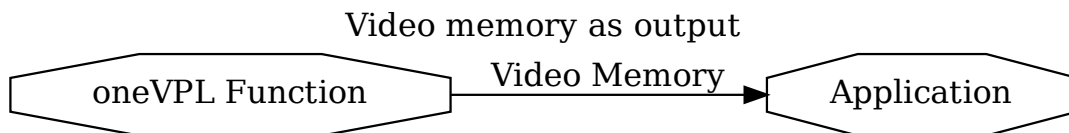

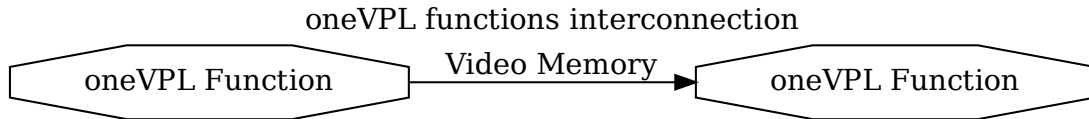

See the `MFXQueryAdapters()` description for adapter priority rules.

Work with Video Memory

To fully utilize the oneVPL acceleration capability, the application should support OS specific infrastructures. If using Microsoft* Windows*, the application should support Microsoft DirectX*. If using Linux*, the application should support the VA API for Linux.

The hardware acceleration support in an application consists of video memory support and acceleration device support.

Depending on the usage model, the application can use video memory at different stages in the pipeline. Three major scenarios are shown in the following diagrams:

The application must use the `mfxVideoParam::IOPattern` field to indicate the I/O access pattern during initialization. Subsequent function calls must follow this access pattern. For example, if a function operates on video memory surfaces at both input and output, the application must specify the access pattern `IOPattern` at initialization in `MFX_IOPATTERN_IN_VIDEO_MEMORY` for input and `MFX_IOPATTERN_OUT_VIDEO_MEMORY` for output. This particular I/O access pattern must not change inside the **Init - Close** sequence.

Initialization of any hardware accelerated oneVPL component requires the acceleration device handle. This handle is also used by the oneVPL component to query hardware capabilities. The application can share its device with oneVPL by passing the device handle through the `MFXVideoCORE_SetHandle()` function. It is recommended to share the handle before any actual usage of oneVPL.

Work with Microsoft DirectX* Applications

oneVPL supports two different infrastructures for hardware acceleration on the Microsoft Windows OS: the Direct3D* 9 DXVA2 and Direct3D 11 Video API. If Direct3D 9 DXVA2 is used for hardware acceleration, the application should use the *IDirect3DDeviceManager9* interface as the acceleration device handle. If the Direct3D 11 Video API is used for hardware acceleration, the application should use the *ID3D11Device* interface as the acceleration device handle.

The application should share one of these interfaces with oneVPL through the *MFVideoCORE_SetHandle()* function. If the application does not provide the interface, then oneVPL creates its own internal acceleration device. As a result, oneVPL input and output will be limited to system memory only for the external allocation mode, which will reduce oneVPL performance. If oneVPL fails to create a valid acceleration device, then oneVPL cannot proceed with hardware acceleration and returns an error status to the application.

Note: It is recommended to work in the internal allocation mode if the application does not provide the *IDirect3DDeviceManager9* or *ID3D11Device* interface.

The application must create the Direct3D 9 device with the flag `D3DCREATE_MULTITHREADED`. The flag `D3DCREATE_FPU_PRESERVE` is also recommended. This influences floating-point calculations, including PTS values.

The application must also set multi-threading mode for the Direct3D 11 device. The following example shows how to set multi-threading mode for a Direct3D 11 device:

```

1 ID3D11Device          *pD11Device;
2 ID3D11DeviceContext  *pD11Context;
3 ID3D10Multithread    *pD10Multithread;
4
5 pD11Device->GetImmediateContext(&pD11Context);
6 pD11Context->QueryInterface(IID_ID3D10Multithread, &pD10Multithread);
7 pD10Multithread->SetMultithreadProtected(true);

```

During hardware acceleration, if a Direct3D “device lost” event occurs, the oneVPL operation terminates with the *mfStatus::MF_ERR_DEVICE_LOST* return status. If the application provided the Direct3D device handle, the application must reset the Direct3D device.

When the oneVPL decoder creates auxiliary devices for hardware acceleration, it must allocate the list of Direct3D surfaces for I/O access, also known as the surface chain, and pass the surface chain as part of the device creation command. In most cases, the surface chain is the frame surface pool mentioned in the *Frame Surface Locking* section.

The application passes the surface chain to the oneVPL component **Init** function through a oneVPL external allocator callback. See the *Memory Allocation and External Allocators* section for details.

Only the decoder **Init** function requests the external surface chain from the application and uses it for auxiliary device creation. Encoder and VPP **Init** functions may only request internal surfaces. See the *ExtMemFrameType enumerator* for more details about different memory types.

Depending on configuration parameters, oneVPL requires different surface types. It is strongly recommended to call the *MFVideoENCODE_QueryIOSurf()* function, the *MFVideoDECODE_QueryIOSurf()* function, or the *MFVideoVPP_QueryIOSurf()* function to determine the appropriate type in the external allocation mode.

Work with VA API Applications

oneVPL supports the VA API infrastructure for hardware acceleration on Linux. The application should use the *VADisplay* interface as the acceleration device handle for this infrastructure and share it with oneVPL through the *MFVideoCORE_SetHandle()* function.

The following example shows how to obtain the VA display from the X Window System:

```

1 Display *x11_display;
2 VADisplay va_display;
3
4 x11_display = XOpenDisplay(current_display);
5 va_display = vaGetDisplay(x11_display);
6
7 MFVideoCORE_SetHandle(session, MFX_HANDLE_VA_DISPLAY, (mfxHDL) va_display);

```

The following example shows how to obtain the VA display from the Direct Rendering Manager:

```

1 int card;
2 VADisplay va_display;
3
4 card = open("/dev/dri/card0", O_RDWR); /* primary card */
5 va_display = vaGetDisplayDRM(card);
6 vaInitialize(va_display, &major_version, &minor_version);
7
8 MFVideoCORE_SetHandle(session, MFX_HANDLE_VA_DISPLAY, (mfxHDL) va_display);

```

When the oneVPL decoder creates a hardware acceleration device, it must allocate the list of video memory surfaces for I/O access, also known as the surface chain, and pass the surface chain as part of the device creation command. The application passes the surface chain to the oneVPL component **Init** function through a oneVPL external allocator callback. See the *Memory Allocation and External Allocators* section for details. Starting from oneVPL API version 2.0, oneVPL creates its own surface chain if an external allocator is not set. See the *New Model to work with Hardware Acceleration* <hw-acceleration>` section for details.

Note: The VA API does not define any surface types and the application can use either *MFX_MEMTYPE_VIDEO_MEMORY_DECODER_TARGET* or *MFX_MEMTYPE_VIDEO_MEMORY_PROCESSOR_TARGET* to indicate data in video memory.

10.3.9 Memory Allocation and External Allocators

There are two models of memory management in oneVPL: internal and external.

External Memory Management

In the external memory model, the application must allocate sufficient memory for input and output parameters and buffers and deallocate it when oneVPL functions complete their operations. During execution, the oneVPL functions use callback functions to the application to manage memory for video frames through the external allocator interface *mfxfFrameAllocator*.

If an application needs to control the allocation of video frames, it can use callback functions through the *mfxfFrameAllocator* interface. If an application does not specify an allocator, an internal allocator is used. However, if an application uses video memory surfaces for input and output, it must specify the hardware acceleration device and an external frame allocator using *mfxfFrameAllocator*.

The external frame allocator can allocate different frame types:

- In-system memory.
- In-video memory, as ‘Decoder Render Targets’ or ‘Processor Render Targets.’ See *Working with Hardware Acceleration* for additional details.

The external frame allocator responds only to frame allocation requests for the requested memory type and returns *mfxfStatus::MFX_ERR_UNSUPPORTED* for all other types. The allocation request uses flags (part of the memory type field) to indicate which oneVPL class initiated the request so that the external frame allocator can respond accordingly.

The following example shows a simple external frame allocator:

```

1 #define ALIGN32(X) (((mfxU32)(X)+31) & (~ (mfxU32)31))
2
3 typedef struct {
4     mfxU16 width, height;
5     mfxU8 *base;
6 } mid_struct;
7
8 mfxStatus fa_alloc(mfxHDL pthis, mfxFrameAllocRequest *request, mfxFrameAllocResponse_
↵ *response) {
9     UNUSED_PARAM(pthis);
10    if (!(request->Type&MFX_MEMTYPE_SYSTEM_MEMORY))
11        return MFX_ERR_UNSUPPORTED;
12    if (request->Info.FourCC!=MFX_FOURCC_NV12)
13        return MFX_ERR_UNSUPPORTED;
14    response->NumFrameActual=request->NumFrameMin;
15    for (int i=0;i<request->NumFrameMin;i++) {
16        mid_struct *mmid=(mid_struct *)malloc(sizeof(mid_struct));
17        mmid->width=ALIGN32(request->Info.Width);
18        mmid->height=ALIGN32(request->Info.Height);
19        mmid->base=(mfxU8*)malloc(mmid->width*mmid->height*3/2);
20        response->mids[i]=mmid;
21    }
22    return MFX_ERR_NONE;
23 }
24
25 mfxStatus fa_lock(mfxHDL pthis, mfxMemId mid, mfxFrameData *ptr) {
26     UNUSED_PARAM(pthis);

```

(continues on next page)

(continued from previous page)

```

27     mid_struct *mmid=(mid_struct *)mid;
28     ptr->Pitch=mmid->width;
29     ptr->Y=mmid->base;
30     ptr->U=ptr->Y+mmid->width*mmid->height;
31     ptr->V=ptr->U+1;
32     return MFX_ERR_NONE;
33 }
34
35 mfxStatus fa_unlock(mfxHDL pthis, mfxMemId mid, mfxFrameData *ptr) {
36     UNUSED_PARAM(pthis);
37     UNUSED_PARAM(mid);
38     if (ptr) ptr->Y=ptr->U=ptr->V=ptr->A=0;
39     return MFX_ERR_NONE;
40 }
41
42 mfxStatus fa_gethdl(mfxHDL pthis, mfxMemId mid, mfxHDL *handle) {
43     UNUSED_PARAM(pthis);
44     UNUSED_PARAM(mid);
45     UNUSED_PARAM(handle);
46     return MFX_ERR_UNSUPPORTED;
47 }
48
49 mfxStatus fa_free(mfxHDL pthis, mfxFrameAllocResponse *response) {
50     UNUSED_PARAM(pthis);
51     for (int i=0;i<response->NumFrameActual;i++) {
52         mid_struct *mmid=(mid_struct *)response->mids[i];
53         free(mmid->base); free(mmid);
54     }
55     return MFX_ERR_NONE;
56 }

```

For system memory, it is highly recommended to allocate memory for all planes of the same frame as a single buffer (using one single malloc call).

Internal Memory Management

In the internal memory management model, oneVPL provides interface functions for frames allocation:

- [*MFXMemory_GetSurfaceForVPP\(\)*](#)
- [*MFXMemory_GetSurfaceForVPPOut\(\)*](#)
- [*MFXMemory_GetSurfaceForEncode\(\)*](#)
- [*MFXMemory_GetSurfaceForDecode\(\)*](#)

These functions are used together with [*mfxFrameSurfaceInterface*](#) for surface management. The surface returned by these functions is a reference counted object and the application must call [*mfxFrameSurfaceInterface::Release*](#) after finishing all operations with the surface. In this model the application does not need to create and set the external allocator to oneVPL.

Another method to obtain an internally allocated surface is to call [*MFXVideoDECODE_DecodeFrameAsync\(\)*](#) with a working surface equal to NULL (see [*Simplified decoding procedure*](#)). In this scenario, the decoder will allocate a new refcountable [*mfxFrameSurface1*](#) and return it to the user. All assumed contracts with the user are similar to the [*MFXMemory_GetSurfaceForXXX*](#) functions.

mfxfFrameSurfaceInterface

oneVPL API version 2.0 introduces *mfxfFrameSurfaceInterface*. This interface is a set of callback functions to manage the lifetime of allocated surfaces, get access to pixel data, and obtain native handles and device abstractions (if suitable). Instead of directly accessing *mfxfFrameSurface1* structure members, it's recommended to use the *mfxfFrameSurfaceInterface* if present or call external allocator callback functions if set.

The following pseudo code shows the usage of *mfxfFrameSurfaceInterface* for memory sharing:

```

1 // lets decode frame and try to access output in an optimal way.
2 sts = MFXVideoDECODE_DecodeFrameAsync(session, NULL, NULL, &outsurface, &syncp);
3 if (MFX_ERR_NONE == sts)
4 {
5     mfxStatus s = outsurface->FrameInterface->GetDeviceHandle(outsurface,
6                                     &device_handle, &device_type);
7     // if application or component is familiar with mfxHandleType and it's
8     // possible to share memory created by device_handle.
9     if (MFX_ERR_NONE == s && isDeviceTypeCompatible(device_type)
10         && isPossibleForMemorySharing(device_handle)) {
11         // get native handle and type
12         outsurface->FrameInterface->GetNativeHandle(outsurface,
13                                                     &resource, &resource_type);
14         if (isResourceTypeCompatible(resource_type)) {
15             //use memory directly
16             ProcessNativeMemory(resource);
17             outsurface->FrameInterface->Release(outsurface);
18         }
19     } else {
20         // Application or component is not aware about such DeviceHandle or
21         // Resource type need to map to system memory.
22         outsurface->FrameInterface->Map(outsurface, MFX_MAP_READ);
23         ProcessSystemMemory(outsurface);
24         outsurface->FrameInterface->Unmap(outsurface);
25         outsurface->FrameInterface->Release(outsurface);
26     }
27 }

```

10.3.10 Hardware Device Error Handling

For implementations that accelerate decoding, encoding, and video processing through a hardware device, API functions may return errors or warnings if the hardware device encounters errors. See the *Hardware Device Errors and Warnings table* for detailed information about the errors and warnings.

Table 8: Hardware Device Errors and Warnings

Status	Description
<code>mfxfStatus::MFX_ERR_DEVICE_FAILED</code>	Hardware device returned unexpected errors. oneVPL was unable to restore operation.
<code>mfxfStatus::MFX_ERR_DEVICE_LOST</code>	Hardware device was lost due to system lock or shutdown.
<code>mfxfStatus::MFX_WRN_PARTIAL_ACCELERATION</code>	The hardware does not fully support the specified configuration. The encoding, decoding, or video processing operation may be partially accelerated.
<code>mfxfStatus::MFX_WRN_DEVICE_BUSY</code>	Hardware device is currently busy.

oneVPL **Query**, **QueryIOSurf**, and **Init** functions return `mfxfStatus::MFX_WRN_PARTIAL_ACCELERATION` to indicate that the encoding, decoding, or video processing operation can be partially hardware accelerated or not hardware accelerated at all. The application can ignore this warning and proceed with the operation. (Note that oneVPL functions may return errors or other warnings overwriting `mfxfStatus::MFX_WRN_PARTIAL_ACCELERATION`, as it is a lower priority warning.)

oneVPL functions return `mfxfStatus::MFX_WRN_DEVICE_BUSY` to indicate that the hardware device is busy and unable to receive commands at this time. The recommended approach is:

- If the asynchronous operation returns synchronization point along with `mfxfStatus::MFX_WRN_DEVICE_BUSY` - call the `MFXVideoCORE_SyncOperation()` with it.
- If application has buffered synchronization point(s) obtained from previous asynchronous operations - call `MFXVideoCORE_SyncOperation()` with the oldest one.
- If no synchronization point(s) available - wait for a few milliseconds.
- Resume the operation by resubmitting the request.

```

1 mfxStatus sts=MFX_ERR_NONE;
2 for (;;) {
3     // do something
4     sts=MFXVideoDECODE_DecodeFrameAsync(session, bitstream, surface_work, &surface_disp,
↳&syncp);
5     if (sts == MFX_ERR_NONE) buffered_syncp = syncp;
6     else if (sts == MFX_WRN_DEVICE_BUSY) prg_handle_device_busy(session, syncp ? syncp :
↳buffered_syncp);
7
8 }

```

The same procedure applies to encoding and video processing.

oneVPL functions return `mfxfStatus::MFX_ERR_DEVICE_LOST` or `mfxfStatus::MFX_ERR_DEVICE_FAILED` to indicate that there is a complete failure in hardware acceleration. The application must close and reinitialize the oneVPL function class. If the application has provided a hardware acceleration device handle to oneVPL, the application must reset the device.

10.4 Mandatory APIs and Functions

10.4.1 Disclaimer

Developers can implement any subset of the oneVPL API. The specification makes no claim about what encoder, decoder, VPP filter, or any other underlying features are mandatory for the implementation. The oneVPL API is designed such that users have several options to discover capabilities exposed by the implementation:

1. Before or after session creation: Users can get a list of supported encoders, decoders, VPP filters, correspondent color formats, and memory types with the help of the `MFXEnumImplementations()` function. For more details, see *oneVPL Dispatcher Interactions*.
2. After session is created: Users can call **Query** functions to obtain low level implementation capabilities.

Attention: The legacy Intel® Media Software Development Kit implementation does not support the first approach to obtain capabilities.

10.4.2 Exported Functions

The *Exported Functions table* lists all functions that must be exposed by any oneAPI Video Processing Library implementation. The realization of all listed functions is mandatory; most functions may return `mfxStatus::MFX_ERR_NOT_IMPLEMENTED`.

Note: Functions `MFXInit()` and `MFXInitEx()` are not required to be exported.

See *Mandatory APIs* for details about which functions, in which conditions, must not return `mfxStatus::MFX_ERR_NOT_IMPLEMENTED`.

Table 9: Exported Functions

Function	API Version
<code>MFXClose()</code>	1.0
<code>MFXQueryIMPL()</code>	1.0
<code>MFXQueryVersion()</code>	1.0
<code>MFXJoinSession()</code>	1.1
<code>MFXDisjoinSession()</code>	1.1
<code>MFXCloneSession()</code>	1.1
<code>MFXSetPriority()</code>	1.1

10.4.3 Mandatory APIs

All implementations must implement the APIs listed in the *Mandatory APIs table*:

Table 10: Mandatory APIs

Functions	Description
<i>MFXInitialize()</i> <i>MFXClose()</i>	Required functions for the dispatcher to create a session.
<i>MFXQueryImplsDescription()</i> <i>MFXReleaseImplDescription()</i>	Required functions for the dispatcher to return implementation capabilities.
<i>MFXVideoCORE_SyncOperation()</i>	Required function for synchronization of asynchronous operations.

If the implementation exposes any encoder, decoder, or VPP filter, it must implement the corresponding mandatory APIs, as described in the *Mandatory Encode, Decode, VPP* and *Decode+VPP* APIs tables:

Table 11: Mandatory Encode APIs

Functions	Description
<i>MFXVideoENCODE_Init()</i> <i>MFXVideoENCODE_Close()</i> <i>MFXVideoENCODE_Query()</i> <i>MFXVideoENCODE_EncodeFrameAsync()</i>	Required functions if the implementation implements any encoder.

Table 12: Mandatory Decode APIs

Functions	Description
<i>MFXVideoDECODE_Init()</i> <i>MFXVideoDECODE_Close()</i> <i>MFXVideoDECODE_Query()</i> <i>MFXVideoDECODE_DecodeFrameAsync()</i>	Required functions if the implementation implements any decoder.

Table 13: Mandatory VPP APIs

Functions	Description
<i>MFXVideoVPP_Init()</i> <i>MFXVideoVPP_Close()</i> <i>MFXVideoVPP_Query()</i> <i>MFXVideoVPP_RunFrameVPPAsync()</i> or <i>MFXVideoVPP_ProcessFrameAsync()</i>	Required functions if the implementation implements any VPP filter.

Table 14: Mandatory Decode+VPP APIs

Functions	Description
<i>MFXVideoDECODE_VPP_Init()</i> <i>MFXVideoDECODE_VPP_DecodeFrameAsync()</i> <i>MFXVideoDECODE_VPP_Close()</i>	Required functions if the implementation implements any Decode+VPP component.

Note: Mandatory functions must not return the *MFX_ERR_NOT_IMPLEMENTED* status.

If at least one of the encoder, decoder, or VPP filter functions is implemented, the *MFXQueryImplsDescription()* function must return a valid *mfxImplDescription* structure instance with mandatory capabilities of the implementation, including decoder, encoder, or VPP capabilities information.

If the implementation supports internal memory allocation by exposing at least one of the function from that family: *internal memory allocation and management API* then implementation of whole scope of the *mfxFrameSurfaceInterface* structure as a part of the *mfxFrameSurface1* is mandatory.

Any other functions or extension buffers are optional for the implementation.

10.5 oneVPL API Reference

10.5.1 Function Reference

VideoDECODE Functions that implement a complete decoder that decompresses input bitstreams directly to output frame surfaces.

VideoENCODE Functions that perform the entire encoding pipeline from the input video frames to the output bitstream.

VideoVPP Functions that perform video processing before encoding, rendering, or standalone.

VideoCORE Functions to perform external device and memory management and synchronization.

Session Management Functions to manage sessions.

Memory Functions for internal memory allocation and management.

Implementation Capabilities Functions to report capabilities of available implementations and create user-requested library implementations.

Adapters Functions that identify graphics adapters for Microsoft* DirectX* video processing, encoding, and decoding.

VideoDECODE_VPP Functions that implement combined operation of decoding and video processing with multiple output frame surfaces.

VideoDECODE

Functions that implement a complete decoder that decompresses input bitstreams directly to output frame surfaces.

API

- *MFXVideoDECODE_Query*
- *MFXVideoDECODE_DecodeHeader*
- *MFXVideoDECODE_QueryIOSurf*
- *MFXVideoDECODE_Init*
- *MFXVideoDECODE_Reset*
- *MFXVideoDECODE_Close*
- *MFXVideoDECODE_GetVideoParam*
- *MFXVideoDECODE_GetDecodeStat*
- *MFXVideoDECODE_SetSkipMode*
- *MFXVideoDECODE_GetPayload*
- *MFXVideoDECODE_DecodeFrameAsync*

MFXVideoDECODE_Query

mfxStatus **MFXVideoDECODE_Query**(*mfxSession* session, *mfxVideoParam* *in, *mfxVideoParam* *out)

Works in one of two modes:

- If the *in* parameter is zero, the function returns the class configurability in the output structure. A non-zero value in each field of the output structure indicates that the field is configurable by the implementation with the *MFXVideoDECODE_Init* function.
- If the *in* parameter is non-zero, the function checks the validity of the fields in the input structure. Then the function returns the corrected values to the output structure. If there is insufficient information to determine the validity or correction is impossible, the function zeros the fields. This feature can verify whether the implementation supports certain profiles, levels, or bitrates.

The application can call this function before or after it initializes the decoder. The *CodecId* field of the output structure is a mandated field (to be filled by the application) to identify the coding standard.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **in** – [in] Pointer to the *mfxVideoParam* structure as input.
- **out** – [out] Pointer to the *mfxVideoParam* structure as output.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_UNSUPPORTED The function failed to identify a specific implementation for the required features.

MFX_WRN_PARTIAL_ACCELERATION The underlying hardware does not fully support the specified video parameters. The decoding may be partially accelerated. Only hardware implementations may return this status code.

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

Important: The *MFXVideoDECODE_Query()* is mandatory when implementing a decoder.

MFXVideoDECODE_DecodeHeader

mfxStatus **MFXVideoDECODE_DecodeHeader**(*mfxSession* session, *mfxBitstream* *bs, *mfxVideoParam* *par)

Parses the input bitstream and fills the *mfxVideoParam* structure with appropriate values, such as resolution and frame rate, for the Init API function.

The application can then pass the resulting structure to the *MFXVideoDECODE_Init* function for decoder initialization.

An application can call this API function at any time before or after decoder initialization. If the library finds a sequence header in the bitstream, the function moves the bitstream pointer to the first bit of the sequence header. Otherwise, the function moves the bitstream pointer close to the end of the bitstream buffer but leaves enough data in the buffer to avoid possible loss of start code.

The *CodecId* field of the *mfxVideoParam* structure is a mandated field (to be filled by the application) to identify the coding standard.

The application can retrieve a copy of the bitstream header, by attaching the *mfxExtCodingOptionSPSPPS* structure to the *mfxVideoParam* structure.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **bs** – [in] Pointer to the bitstream.
- **par** – [in] Pointer to the *mfxVideoParam* structure.

Returns

- **MFX_ERR_NONE** The function successfully filled the structure. It does not mean that the stream can be decoded by the library. The application should call *MFXVideoDECODE_Query* function to check if decoding of the stream is supported.

- `MFX_ERR_MORE_DATA` The function requires more bitstream data.
- `MFX_ERR_UNSUPPORTED` CodecId field of the *mfxVideoParam* structure indicates some unsupported codec.
- `MFX_ERR_INVALID_HANDLE` Session is not initialized.
- `MFX_ERR_NULL_PTR` bs or par pointer is NULL.

MFXVideoDECODE_QueryIOSurf

mfxStatus **MFXVideoDECODE_QueryIOSurf**(*mfxSession* session, *mfxVideoParam* *par, *mfxFrameAllocRequest* *request)

Returns minimum and suggested numbers of the output frame surfaces required for decoding initialization and their type.

Init will call the external allocator for the required frames with the same set of numbers. The use of this function is recommended. For more information, see the *Working with Hardware Acceleration section*.

The CodecId field of the *mfxVideoParam* structure is a mandated field (to be filled by the application) to identify the coding standard. This function does not validate I/O parameters except those used in calculating the number of output surfaces.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxVideoParam* structure as input.
- **request** – [in] Pointer to the *mfxFrameAllocRequest* structure as output.

Returns

`MFX_ERR_NONE` The function completed successfully.

`MFX_ERR_INVALID_VIDEO_PARAM` The function detected invalid video parameters. These parameters may be out of the valid range, or the combination of them resulted in incompatibility. Incompatibility not resolved.

`MFX_WRN_PARTIAL_ACCELERATION` The underlying hardware does not fully support the specified video parameters. The encoding may be partially accelerated. Only hardware implementations may return this status code.

`MFX_WRN_INCOMPATIBLE_VIDEO_PARAM` The function detected some video parameters were incompatible with others; incompatibility resolved.

MFVideoDECODE_Init

mfxStatus **MFVideoDECODE_Init**(*mfxSession* session, *mfxVideoParam* *par)

Allocates memory and prepares tables and necessary structures for encoding.

This function also does extensive validation to ensure if the configuration, as specified in the input parameters, is supported.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxVideoParam* structure.

Returns

MF_ERR_NONE The function completed successfully.

MF_ERR_INVALID_VIDEO_PARAM The function detected invalid video parameters. These parameters may be out of the valid range, or the combination of them resulted in incompatibility. Incompatibility not resolved.

MF_WRN_PARTIAL_ACCELERATION The underlying hardware does not fully support the specified video parameters. The encoding may be partially accelerated. Only hardware implementations may return this status code.

MF_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

MF_ERR_UNDEFINED_BEHAVIOR The function is called twice without a close.

Important: The *MFVideoDECODE_Init()* is mandatory when implementing a decoder.

MFVideoDECODE_Reset

mfxStatus **MFVideoDECODE_Reset**(*mfxSession* session, *mfxVideoParam* *par)

Stops the current decoding operation and restores internal structures or parameters for a new decoding operation.

Reset serves two purposes:

- It recovers the decoder from errors.
- It restarts decoding from a new position

The function resets the old sequence header (sequence parameter set in H.264, or sequence header in MPEG-2 and VC-1). The decoder will expect a new sequence header before it decodes the next frame and will skip any bitstream before encountering the new sequence header.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfXVideoParam* structure.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_INVALID_VIDEO_PARAM The function detected that video parameters are wrong or they conflict with initialization parameters. Reset is impossible.

MFX_ERR_INCOMPATIBLE_VIDEO_PARAM The function detected that video parameters provided by the application are incompatible with initialization parameters. Reset requires additional memory allocation and cannot be executed. The application should close the component and then reinitialize it.

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

MFXVideoDECODE_Close

mfXStatus **MFXVideoDECODE_Close**(*mfXSession* session)

Terminates the current decoding operation and de-allocates any internal tables or structures.

Since This function is available since API version 1.0.

Parameters **session** – [in] Session handle.

Returns **MFX_ERR_NONE** The function completed successfully.

Important: The *MFXVideoDECODE_Close()* is mandatory when implementing a decoder.

MFXVideoDECODE_GetVideoParam

mfXStatus **MFXVideoDECODE_GetVideoParam**(*mfXSession* session, *mfXVideoParam* *par)

Retrieves current working parameters to the specified output structure.

If extended buffers are to be returned, the application must allocate those extended buffers and attach them as part of the output structure. The application can retrieve a copy of the bitstream header, by attaching the *mfXExtCodingOptionSPSPS* structure to the *mfXVideoParam* structure.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the corresponding parameter structure.

Returns **MFX_ERR_NONE** The function completed successfully.

MFVideoDECODE_GetDecodeStat

mfxStatus **MFVideoDECODE_GetDecodeStat** (*mfxSession* session, *mfxDecodeStat* *stat)
Obtains statistics collected during decoding.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **stat** – [in] Pointer to the *mfxDecodeStat* structure.

Returns MFX_ERR_NONE The function completed successfully.

MFVideoDECODE_SetSkipMode

mfxStatus **MFVideoDECODE_SetSkipMode** (*mfxSession* session, *mfxSkipMode* mode)
Sets the decoder skip mode.

The application may use this API function to increase decoding performance by sacrificing output quality. Increasing the skip level first results in skipping of some decoding operations like deblocking and then leads to frame skipping; first B, then P. Particular details are platform dependent.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **mode** – [in] Decoder skip mode. See the *mfxSkipMode* enumerator for details.

Returns

MFX_ERR_NONE The function completed successfully and the output surface is ready for decoding

MFX_WRN_VALUE_NOT_CHANGED The skip mode is not affected as the maximum or minimum skip range is reached.

MFVideoDECODE_GetPayload

mfxStatus **MFVideoDECODE_GetPayload** (*mfxSession* session, *mfxU64* *ts, *mfxPayload* *payload)
Extracts user data (MPEG-2) or SEI (H.264) messages from the bitstream.

Internally, the decoder implementation stores encountered user data or SEI messages. The application may call this API function multiple times to retrieve the user data or SEI messages, one at a time.

If there is no payload available, the function returns with `payload->NumBit=0`.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.

- **ts** – [in] Pointer to the user data time stamp in units of 90 KHz; divide ts by 90,000 (90 KHz) to obtain the time in seconds; the time stamp matches the payload with a specific decoded frame.
- **payload** – [in] Pointer to the *mfxFayload* structure; the payload contains user data in MPEG-2 or SEI messages in H.264.

Returns

MFX_ERR_NONE The function completed successfully and the output buffer is ready for decoding.

MFX_ERR_NOT_ENOUGH_BUFFER The payload buffer size is insufficient.

MFXVideoDECODE_DecodeFrameAsync

mfxFStatus **MFXVideoDECODE_DecodeFrameAsync**(*mfxFSession* session, *mfxFBitstream* *bs, *mfxFFrameSurface1* *surface_work, *mfxFFrameSurface1* **surface_out, *mfxFSyncPoint* *syncp)

Decodes the input bitstream to a single output frame.

The *surface_work* parameter provides a working frame buffer for the decoder. The application should allocate the working frame buffer, which stores decoded frames. If the function requires caching frames after decoding, it locks the frames and the application must provide a new frame buffer in the next call.

If, and only if, the function returns **MFX_ERR_NONE**, the pointer *surface_out* points to the output frame in the display order. If there are no further frames, the function will reset the pointer to zero and return the appropriate status code.

Before decoding the first frame, a sequence header (sequence parameter set in H.264 or sequence header in MPEG-2 and VC-1) must be present. The function skips any bitstreams before it encounters the new sequence header.

The input bitstream *bs* can be of any size. If there are not enough bits to decode a frame, the function returns **MFX_ERR_MORE_DATA**, and consumes all input bits except if a partial start code or sequence header is at the end of the buffer. In this case, the function leaves the last few bytes in the bitstream buffer. If there is more incoming bitstream, the application should append the incoming bitstream to the bitstream buffer. Otherwise, the application should ignore the remaining bytes in the bitstream buffer and apply the end of stream procedure described below.

The application must set *bs* to **NULL** to signal end of stream. The application may need to call this API function several times to drain any internally cached frames until the function returns **MFX_ERR_MORE_DATA**.

If more than one frame is in the bitstream buffer, the function decodes until the buffer is consumed. The decoding process can be interrupted for events such as if the decoder needs additional working buffers, is readying a frame for retrieval, or encountering a new header. In these cases, the function returns appropriate status code and moves the bitstream pointer to the remaining data.

The decoder may return **MFX_ERR_NONE** without taking any data from the input bitstream buffer. If the application appends additional data to the bitstream buffer, it is possible that the bitstream buffer may contain more than one frame. It is recommended that the application invoke the function repeatedly until the function returns **MFX_ERR_MORE_DATA**, before appending any more data to the bitstream buffer.

Starting from API 2.0 it is possible to pass **NULL** instead of *surface_work*. In such case runtime will allocate output frames internally.

This function is asynchronous.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **bs** – [in] Pointer to the input bitstream.
- **surface_work** – [in] Pointer to the working frame buffer for the decoder.
- **surface_out** – [out] Pointer to the output frame in the display order.
- **syncp** – [out] Pointer to the sync point associated with this operation.

Returns

MFX_ERR_NONE The function completed successfully and the output surface is ready for decoding.

MFX_ERR_MORE_DATA The function requires more bitstream at input before decoding can proceed.

MFX_ERR_MORE_SURFACE The function requires more frame surface at output before decoding can proceed.

MFX_ERR_DEVICE_LOST Hardware device was lost.

See the *Working with Microsoft* DirectX* Applications section* for further information.

MFX_WRN_DEVICE_BUSY Hardware device is currently busy. Call this function again after `MFXVideoCORE_SyncOperation` or in a few milliseconds.

MFX_WRN_VIDEO_PARAM_CHANGED The decoder detected a new sequence header in the bitstream. Video parameters may have changed.

MFX_ERR_INCOMPATIBLE_VIDEO_PARAM The decoder detected incompatible video parameters in the bitstream and failed to follow them.

MFX_ERR_REALLOC_SURFACE Bigger `surface_work` required. May be returned only if *mfxf-InfoMFX::EnableReallocRequest* was set to ON during initialization.

MFX_WRN_ALLOC_TIMEOUT_EXPIRED Timeout expired for internal output frame allocation (if set with *mfxfExtAllocationHints* and NULL passed as `surface_work`). Repeat the call in a few milliseconds or re-initialize decoder with higher surface limit.

Important: The `MFXVideoDECODE_DecodeFrameAsync()` is mandatory when implementing a decoder.

VideoENCODE

Functions that perform the entire encoding pipeline from the input video frames to the output bitstream.

API

- *MFXVideoENCODE_Query*
- *MFXVideoENCODE_QueryIOSurf*
- *MFXVideoENCODE_Init*
- *MFXVideoENCODE_Reset*
- *MFXVideoENCODE_Close*
- *MFXVideoENCODE_GetVideoParam*
- *MFXVideoENCODE_GetEncodeStat*
- *MFXVideoENCODE_EncodeFrameAsync*

MFXVideoENCODE_Query

mfxStatus **MFXVideoENCODE_Query**(*mfxSession* session, *mfxVideoParam* *in, *mfxVideoParam* *out)

Works in either of four modes:

- If the *in* parameter is zero, the function returns the class configurability in the output structure. The application must set to zero the fields it wants to check for support. If the field is supported, function sets non-zero value to this field, otherwise it would be ignored. It indicates that the SDK implementation can configure the field with Init.
- If the *in* parameter is non-zero, the function checks the validity of the fields in the input structure. Then the function returns the corrected values in the output structure. If there is insufficient information to determine the validity or correction is impossible, the function zeroes the fields. This feature can verify whether the implementation supports certain profiles, levels or bitrates.
- If the *in* parameter is non-zero and *mfxExtEncoderResetOption* structure is attached to it, the function queries for the outcome of the *MFXVideoENCODE_Reset* function and returns it in the *mfxExtEncoderResetOption* structure attached to out. The query function succeeds if a reset is possible and returns an error otherwise. Unlike other modes that are independent of the encoder state, this one checks if reset is possible in the present encoder state. This mode also requires a completely defined *mfxVideoParam* structure, unlike other modes that support partially defined configurations. See *mfxExtEncoderResetOption* description for more details.
- If the *in* parameter is non-zero and *mfxExtEncoderCapability* structure is attached to it, the function returns encoder capability in the *mfxExtEncoderCapability* structure attached to out. It is recommended to fill in the *mfxVideoParam* structure and set the hardware acceleration device handle before calling the function in this mode.

The application can call this function before or after it initializes the encoder. The *CodecId* field of the output structure is a mandated field (to be filled by the application) to identify the coding standard.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **in** – [in] Pointer to the *mfxVideoParam* structure as input.
- **out** – [out] Pointer to the *mfxVideoParam* structure as output.

Returns

MFx_ERR_NONE The function completed successfully.

MFx_ERR_UNSUPPORTED The function failed to identify a specific implementation for the required features.

MFx_WRN_PARTIAL_ACCELERATION The underlying hardware does not fully support the specified video parameters. The encoding may be partially accelerated. Only hardware implementations may return this status code.

MFx_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

Important: The *MFxVideoENCODE_Query()* function is mandatory when implementing an encoder.

MFxVideoENCODE_QueryIOSurf

mfxStatus MFxVideoENCODE_QueryIOSurf(*mfxSession* session, *mfxVideoParam* *par, *mfxFrameAllocRequest* *request)

Returns minimum and suggested numbers of the input frame surfaces required for encoding initialization and their type.

Init will call the external allocator for the required frames with the same set of numbers. This function does not validate I/O parameters except those used in calculating the number of input surfaces.

The use of this function is recommended. For more information, see the *Working with Hardware Acceleration section*.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxVideoParam* structure as input.
- **request** – [in] Pointer to the *mfxFrameAllocRequest* structure as output.

Returns

MFx_ERR_NONE The function completed successfully.

MFx_ERR_INVALID_VIDEO_PARAM The function detected invalid video parameters. These parameters may be out of the valid range or the combination of them resulted in incompatibility. Incompatibility not resolved.

MFx_WRN_PARTIAL_ACCELERATION The underlying hardware does not fully support the specified video parameters. The encoding may be partially accelerated. Only hardware implementations may return this status code.

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

MFXVideoENCODE_Init

mfxStatus **MFXVideoENCODE_Init**(*mfxSession* session, *mfxVideoParam* *par)

Allocates memory and prepares tables and necessary structures for encoding.

This function also does extensive validation to ensure if the configuration, as specified in the input parameters, is supported.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxVideoParam* structure.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_INVALID_VIDEO_PARAM The function detected invalid video parameters. These parameters may be out of the valid range, or the combination of them resulted in incompatibility. Incompatibility not resolved.

MFX_WRN_PARTIAL_ACCELERATION The underlying hardware does not fully support the specified video parameters. The encoding may be partially accelerated. Only hardware implementations may return this status code.

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

MFX_ERR_UNDEFINED_BEHAVIOR The function is called twice without a close;

Important: The *MFXVideoENCODE_Init()* function is mandatory when implementing an encoder.

MFXVideoENCODE_Reset

mfxStatus **MFXVideoENCODE_Reset**(*mfxSession* session, *mfxVideoParam* *par)

Stops the current encoding operation and restores internal structures or parameters for a new encoding operation, possibly with new parameters.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxVideoParam* structure.

Returns

MFx_ERR_NONE The function completed successfully.

MFx_ERR_INVALID_VIDEO_PARAM The function detected invalid video parameters. These parameters may be out of the valid range, or the combination of them resulted in incompatibility. Incompatibility not resolved.

MFx_ERR_INCOMPATIBLE_VIDEO_PARAM The function detected that video parameters provided by the application are incompatible with initialization parameters. Reset requires additional memory allocation and cannot be executed. The application should close the component and then reinitialize it.

MFx_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

MFxVideoENCODE_Close

mfXStatus **MFxVideoENCODE_Close**(*mfXSession* session)

Terminates the current encoding operation and de-allocates any internal tables or structures.

Since This function is available since API version 1.0.

Parameters **session** – [in] Session handle.

Returns **MFx_ERR_NONE** The function completed successfully.

Important: The *MFxVideoENCODE_Close()* function is mandatory when implementing an encoder.

MFxVideoENCODE_GetVideoParam

mfXStatus **MFxVideoENCODE_GetVideoParam**(*mfXSession* session, *mfXVideoParam* *par)

Retrieves current working parameters to the specified output structure.

If extended buffers are to be returned, the application must allocate those extended buffers and attach them as part of the output structure. The application can retrieve a copy of the bitstream header by attaching the *mfXExtCodingOptionSPSPS* structure to the *mfXVideoParam* structure.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the corresponding parameter structure.

Returns **MFx_ERR_NONE** The function completed successfully.

MFXVideoENCODE_GetEncodeStat

mfxStatus **MFXVideoENCODE_GetEncodeStat** (*mfxSession* session, *mfxEncodeStat* *stat)

Obtains statistics collected during encoding.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **stat** – [in] Pointer to the *mfxEncodeStat* structure.

Returns MFX_ERR_NONE The function completed successfully.

MFXVideoENCODE_EncodeFrameAsync

mfxStatus **MFXVideoENCODE_EncodeFrameAsync** (*mfxSession* session, *mfxEncodeCtrl* *ctrl, *mfxFrameSurface1* *surface, *mfxBitstream* *bs, *mfxSyncPoint* *syncp)

Takes a single input frame in either encoded or display order and generates its output bitstream.

In the case of encoded ordering, the *mfxEncodeCtrl* structure must specify the explicit frame type. In the case of display ordering, this function handles frame order shuffling according to the GOP structure parameters specified during initialization.

Since encoding may process frames differently from the input order, not every call of the function generates output and the function returns MFX_ERR_MORE_DATA. If the encoder needs to cache the frame, the function locks the frame. The application should not alter the frame until the encoder unlocks the frame. If there is output (with return status MFX_ERR_NONE), the return is a frame's worth of bitstream.

It is the calling application's responsibility to ensure that there is sufficient space in the output buffer. The value *BufferSizeInKB* in the *mfxVideoParam* structure at encoding initialization specifies the maximum possible size for any compressed frames. This value can also be obtained from the *MFVideoENCODE_GetVideoParam* function after encoding initialization.

To mark the end of the encoding sequence, call this function with a NULL surface pointer. Repeat the call to drain any remaining internally cached bitstreams (one frame at a time) until MFX_ERR_MORE_DATA is returned.

This function is asynchronous.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **ctrl** – [in] Pointer to the *mfxEncodeCtrl* structure for per-frame encoding control; this parameter is optional (it can be NULL) if the encoder works in the display order mode.
- **surface** – [in] Pointer to the frame surface structure.
- **bs** – [out] Pointer to the output bitstream.
- **syncp** – [out] Pointer to the returned sync point associated with this operation.

Returns

- MFX_ERR_NONE The function completed successfully.
- MFX_ERR_NOT_ENOUGH_BUFFER The bitstream buffer size is insufficient.
- MFX_ERR_MORE_DATA The function requires more data to generate any output.
- MFX_ERR_DEVICE_LOST Hardware device was lost.

See the *Working with Microsoft* DirectX* Applications section* for further information.

MFX_WRN_DEVICE_BUSY Hardware device is currently busy. Call this function again after MFXVideoCORE_SyncOperation or in a few milliseconds.

MFX_ERR_INCOMPATIBLE_VIDEO_PARAM Inconsistent parameters detected not conforming to Configuration Parameter Constraints.

Important: The *MFXVideoENCODE_EncodeFrameAsync()* function is mandatory when implementing an encoder.

VideoVPP

Functions that perform video processing before encoding, rendering, or standalone.

API

- *MFXVideoVPP_Query*
- *MFXVideoVPP_QueryIOSurf*
- *MFXVideoVPP_Init*
- *MFXVideoVPP_Reset*
- *MFXVideoVPP_Close*
- *MFXVideoVPP_GetVideoParam*
- *MFXVideoVPP_GetVPPStat*
- *MFXVideoVPP_RunFrameVPPAsync*
- *MFXVideoVPP_ProcessFrameAsync*

MFVideoVPP_Query

mfxStatus **MFVideoVPP_Query**(*mfxSession* session, *mfxVideoParam* *in, *mfxVideoParam* *out)

Works in one of two modes:

- If the *in* pointer is zero, the function returns the class configurability in the output structure. A non-zero value in a field indicates that the implementation can configure it with Init.
- If the *in* parameter is non-zero, the function checks the validity of the fields in the input structure. Then the function returns the corrected values to the output structure. If there is insufficient information to determine the validity or correction is impossible, the function zeroes the fields.

The application can call this function before or after it initializes the preprocessor.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **in** – [in] Pointer to the *mfxVideoParam* structure as input.
- **out** – [out] Pointer to the *mfxVideoParam* structure as output.

Returns

MF_ERR_NONE The function completed successfully.

MF_ERR_UNSUPPORTED The implementation does not support the specified configuration.

MF_WRN_PARTIAL_ACCELERATION The underlying hardware does not fully support the specified video parameters. The video processing may be partially accelerated. Only hardware implementations may return this status code.

MF_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

Important: The *MFVideoVPP_Query()* function is mandatory when implementing a VPP filter.

MFVideoVPP_QueryIOSurf

mfxStatus **MFVideoVPP_QueryIOSurf**(*mfxSession* session, *mfxVideoParam* *par, *mfxFrameAllocRequest* request[2])

Returns minimum and suggested numbers of the input frame surfaces required for video processing initialization and their type.

The parameter *request*[0] refers to the input requirements; *request*[1] refers to output requirements. Init will call the external allocator for the required frames with the same set of numbers. This function does not validate I/O parameters except those used in calculating the number of input surfaces.

The use of this function is recommended. For more information, see the *Working with Hardware Acceleration section*.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxFVideoParam* structure as input.
- **request** – [in] Pointer to the *mfxFFrameAllocRequest* structure; use `request[0]` for input requirements and `request[1]` for output requirements for video processing.

Returns

`MXF_ERR_NONE` The function completed successfully.

`MXF_ERR_INVALID_VIDEO_PARAM` The function detected invalid video parameters. These parameters may be out of the valid range, or the combination of them resulted in incompatibility. Incompatibility not resolved.

`MXF_WRN_PARTIAL_ACCELERATION` The underlying hardware does not fully support the specified video parameters. The video processing may be partially accelerated. Only hardware implementations may return this status code.

`MXF_WRN_INCOMPATIBLE_VIDEO_PARAM` The function detected some video parameters were incompatible with others; incompatibility resolved.

MXFVideoVPP_Init

mfxFStatus **MXFVideoVPP_Init**(*mfxFSession* session, *mfxFVideoParam* *par)

Allocates memory and prepares tables and necessary structures for video processing.

This function also does extensive validation to ensure if the configuration, as specified in the input parameters, is supported.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxFVideoParam* structure.

Returns

`MXF_ERR_NONE` The function completed successfully.

`MXF_ERR_INVALID_VIDEO_PARAM` The function detected invalid video parameters. These parameters may be out of the valid range, or the combination of them resulted in incompatibility. Incompatibility not resolved.

`MXF_WRN_PARTIAL_ACCELERATION` The underlying hardware does not fully support the specified video parameters. The video processing may be partially accelerated. Only hardware implementations may return this status code.

`MXF_WRN_INCOMPATIBLE_VIDEO_PARAM` The function detected some video parameters were incompatible with others; incompatibility resolved.

`MXF_ERR_UNDEFINED_BEHAVIOR` The function is called twice without a close.

`MXF_WRN_FILTER_SKIPPED` The VPP skipped one or more filters requested by the application.

Important: The `MFXVideoVPP_Init()` function is mandatory when implementing a VPP filter.

MFXVideoVPP_Reset

mfxfStatus **MFXVideoVPP_Reset**(*mfxfSession* session, *mfxfVideoParam* *par)

Stops the current video processing operation and restores internal structures or parameters for a new operation.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxfVideoParam* structure.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_INVALID_VIDEO_PARAM The function detected that video parameters are wrong or they conflict with initialization parameters. Reset is impossible.

MFX_ERR_INCOMPATIBLE_VIDEO_PARAM The function detected that video parameters provided by the application are incompatible with initialization parameters. Reset requires additional memory allocation and cannot be executed. The application should close the component and then reinitialize it.

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

MFXVideoVPP_Close

mfxfStatus **MFXVideoVPP_Close**(*mfxfSession* session)

Terminates the current video processing operation and de-allocates any internal tables or structures.

Since This function is available since API version 1.0.

Parameters **session** – [in] Session handle.

Returns MFX_ERR_NONE The function completed successfully.

Important: The `MFXVideoVPP_Close()` function is mandatory when implementing a VPP filter.

MFVideoVPP_GetVideoParam

mfxStatus MFVideoVPP_GetVideoParam(*mfxSession* session, *mfxVideoParam* *par)

Retrieves current working parameters to the specified output structure.

If extended buffers are to be returned, the application must allocate those extended buffers and attach them as part of the output structure.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the corresponding parameter structure.

Returns MFX_ERR_NONE The function completed successfully.

MFVideoVPP_GetVPPStat

mfxStatus MFVideoVPP_GetVPPStat(*mfxSession* session, *mfxVPPStat* *stat)

Obtains statistics collected during video processing.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **stat** – [in] Pointer to the *mfxVPPStat* structure.

Returns MFX_ERR_NONE The function completed successfully.

MFVideoVPP_RunFrameVPPAsync

mfxStatus MFVideoVPP_RunFrameVPPAsync(*mfxSession* session, *mfxFrameSurface1* *in, *mfxFrameSurface1* *out, *mfxExtVppAuxData* *aux, *mfxSyncPoint* *syncp)

Processes a single input frame to a single output frame.

Retrieval of the auxiliary data is optional; the encoding process may use it. The video processing process may not generate an instant output given an input. See the *Video Processing Procedures section* for details on how to correctly send input and retrieve output.

At the end of the stream, call this function with the input argument **in**=NULL to retrieve any remaining frames, until the function returns MFX_ERR_MORE_DATA. This function is asynchronous.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **in** – [in] Pointer to the input video surface structure.
- **out** – [out] Pointer to the output video surface structure.

- **aux** – [in] Optional pointer to the auxiliary data structure.
- **syncp** – [out] Pointer to the output sync point.

Returns

MFX_ERR_NONE The output frame is ready after synchronization.

MFX_ERR_MORE_DATA Need more input frames before VPP can produce an output.

MFX_ERR_MORE_SURFACE The output frame is ready after synchronization. Need more surfaces at output for additional output frames available.

MFX_ERR_DEVICE_LOST Hardware device was lost.

See the *Working with Microsoft* DirectX* Applications section* for further information.

MFX_WRN_DEVICE_BUSY Hardware device is currently busy. Call this function again after **MFXVideoCORE_SyncOperation** or in a few milliseconds.

MFXVideoVPP_ProcessFrameAsync

mfxStatus **MFXVideoVPP_ProcessFrameAsync** (*mfxSession* session, *mfxFrameSurface1* *in, *mfxFrameSurface1* **out)

The function processes a single input frame to a single output frame with internal allocation of output frame.

At the end of the stream, call this function with the input argument **in=NULL** to retrieve any remaining frames, until the function returns **MFX_ERR_MORE_DATA**. This function is asynchronous.

Since This function is available since API version 2.1.

Parameters

- **session** – [in] Session handle.
- **in** – [in] Pointer to the input video surface structure.
- **out** – [out] Pointer to the output video surface structure which is reference counted object allocated by the library.

Returns

MFX_ERR_NONE The output frame is ready after synchronization.

MFX_ERR_MORE_DATA Need more input frames before VPP can produce an output.

MFX_ERR_MEMORY_ALLOC The function failed to allocate output video frame.

MFX_ERR_DEVICE_LOST Hardware device was lost.

See the *Working with Microsoft* DirectX* Applications section* for further information.

MFX_WRN_DEVICE_BUSY Hardware device is currently busy. Call this function again after **MFXVideoCORE_SyncOperation** or in a few milliseconds.

MFX_WRN_ALLOC_TIMEOUT_EXPIRED Timeout expired for internal output frame allocation (if set with *mfxExtAllocationHints*). Repeat the call in a few milliseconds or reinitialize VPP with higher surface limit.

Important: Either `MFXVideoVPP_RunFrameVPPAsync()` or `MFXVideoVPP_ProcessFrameAsync()` function is mandatory when implementing a VPP filter.

VideoCORE

Functions to perform external device and memory management and synchronization.

API

- `MFXVideoCORE_SetFrameAllocator`
- `MFXVideoCORE_SetHandle`
- `MFXVideoCORE_GetHandle`
- `MFXVideoCORE_QueryPlatform`
- `MFXVideoCORE_SyncOperation`

MFXVideoCORE_SetFrameAllocator

mfxFStatus **MFXVideoCORE_SetFrameAllocator**(*mfxFSession* session, *mfxFFrameAllocator* *allocator)

Sets the external allocator callback structure for frame allocation.

If the allocator argument is NULL, the library uses the default allocator, which allocates frames from system memory or hardware devices. The behavior of the API is undefined if it uses this function while the previous allocator is in use. A general guideline is to set the allocator immediately after initializing the session.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **allocator** – [in] Pointer to the *mfxFFrameAllocator* structure

Returns MFX_ERR_NONE The function completed successfully.

MFXVideoCORE_SetHandle

mfxFStatus **MFXVideoCORE_SetHandle**(*mfxFSession* session, *mfxFHandleType* type, *mfxFHDL* hdl)

Sets any essential system handle that the library might use.

If the specified system handle is a COM interface, the reference counter of the COM interface will increase. The counter will decrease when the session closes.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **type** – [in] Handle type
- **hdl** – [in] Handle to be set

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_UNDEFINED_BEHAVIOR The same handle is redefined. For example, the function has been called twice with the same handle type or an internal handle has been created before this function call. MFX_ERR_DEVICE_FAILED The SDK cannot initialize using the handle.

MFXVideoCORE_GetHandle

mfxStatus **MFXVideoCORE_GetHandle**(*mfxSession* session, *mfxHandleType* type, *mfxHDL* *hdl)

Obtains system handles previously set by the MFXVideoCORE_SetHandle function.

If the handler is a COM interface, the reference counter of the interface increases. The calling application must release the COM interface.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **type** – [in] Handle type
- **hdl** – [in] Pointer to the handle to be set

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_UNDEFINED_BEHAVIOR Specified handle type not found.

MFXVideoCORE_QueryPlatform

mfxStatus **MFXVideoCORE_QueryPlatform**(*mfxSession* session, *mfxPlatform* *platform)

Returns information about current hardware platform in the Legacy mode.

Since This function is available since API version 1.19.

Parameters

- **session** – [in] Session handle.
- **platform** – [out] Pointer to the *mfxPlatform* structure

Returns MFX_ERR_NONE The function completed successfully.

MFVideoCORE_SyncOperation

mfStatus **MFVideoCORE_SyncOperation**(*mfSession* session, *mfSyncPoint* syncp, *mfU32* wait)

Initiates execution of an asynchronous function not already started and returns the status code after the specified asynchronous operation completes. If wait is zero, the function returns immediately.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **syncp** – [in] Sync point
- **wait** – [in] wait time in milliseconds

Returns

MF_ERR_NONE The function completed successfully.

MF_ERR_NONE_PARTIAL_OUTPUT The function completed successfully, bitstream contains a portion of the encoded frame according to required granularity.

MF_WRN_IN_EXECUTION The specified asynchronous function is in execution.

MF_ERR_ABORTED The specified asynchronous function aborted due to data dependency on a previous asynchronous function that did not complete.

Important: The *MFVideoCORE_SyncOperation()* function is mandatory for any implementation.

Session Management

Functions to manage sessions.

API

- *MFInit*
- *MFInitEx*
- *MFInitialize*
- *MFClose*
- *MFQueryIMPL*
- *MFQueryVersion*
- *MFJoinSession*
- *MFDisjoinSession*
- *MFCloneSession*
- *MFSetPriority*

- *MFXGetPriority*

MFXInit

mfxStatus **MFXInit**(*mfxIMPL* impl, *mfxVersion* *ver, *mfxSession* *session)

Creates and initializes a session in the legacy mode for compatibility with Intel(r) Media SDK applications. This function is deprecated starting from API version 2.0, applications must use MFXLoad with mfxCreateSession to select the implementation and initialize the session.

Call this function before calling any other API function. If the desired implementation specified by *impl* is MFX_IMPL_AUTO, the function will search for the platform-specific implementation. If the function cannot find the platform-specific implementation, it will use the software implementation instead.

The *ver* argument indicates the desired version of the library implementation. The loaded implementation will have an API version compatible to the specified version (equal in the major version number, and no less in the minor version number.) If the desired version is not specified, the default is to use the API version from the library release with which an application is built.

Production applications should always specify the minimum API version that meets the functional requirements. For example, if an application uses only H.264 decoding as described in API v1.0, the application should initialize the library with API v1.0. This ensures backward compatibility.

Deprecated:

Deprecated in API version 2.3. Use MFXLoad and MFXCreateSession to initialize the session. Use MFX_DEPRECATED_OFF macro to turn off the deprecation message visualization.

Since This function is available since API version 1.0.

Parameters

- **impl** – [in] mfxIMPL enumerator that indicates the desired legacy Intel(r) Media SDK implementation.
- **ver** – [in] Pointer to the minimum library version or zero, if not specified.
- **session** – [out] Pointer to the legacy Intel(r) Media SDK session handle.

Returns

MFX_ERR_NONE The function completed successfully. The output parameter contains the handle of the session.

MFX_ERR_UNSUPPORTED The function cannot find the desired legacy Intel(r) Media SDK implementation or version.

MFXInitEx

mfxfStatus **MFXInitEx**(*mfxfInitParam* par, *mfxfSession* *session)

Creates and initializes a session in the legacy mode for compatibility with Intel(r) Media SDK applications. This function is deprecated starting from API version 2.0, applications must use MFXLoad with mfxCreateSession to select the implementation and initialize the session.

Call this function before calling any other API functions. If the desired implementation specified by par is MFX_IMPL_AUTO, the function will search for the platform-specific implementation. If the function cannot find the platform-specific implementation, it will use the software implementation instead.

The argument par.Version indicates the desired version of the implementation. The loaded implementation will have an API version compatible to the specified version (equal in the major version number, and no less in the minor version number.) If the desired version is not specified, the default is to use the API version from the library release with which an application is built.

Production applications should always specify the minimum API version that meets the functional requirements. For example, if an application uses only H.264 decoding as described in API v1.0, the application should initialize the library with API v1.0. This ensures backward compatibility.

The argument par.ExternalThreads specifies threading mode. Value 0 means that the implementation should create and handle work threads internally (this is essentially the equivalent of the regular MFXInit).

Deprecated:

Deprecated in API version 2.3. Use MFXLoad and MFXCreateSession to initialize the session. Use MFX_DEPRECATED_OFF macro to turn off the deprecation message visualization.

Since This function is available since API version 1.14.

Parameters

- **par** – [in] *mfxfInitParam* structure that indicates the desired implementation, minimum library version and desired threading mode.
- **session** – [out] Pointer to the session handle.

Returns

MFX_ERR_NONE The function completed successfully. The output parameter contains the handle of the session.

MFX_ERR_UNSUPPORTED The function cannot find the desired implementation or version.

MFXInitialize

mfxfStatus **MFXInitialize**(*mfxfInitializationParam* par, *mfxfSession* *session)

Creates and initializes a session starting from API version 2.0. This function is used by the dispatcher. The dispatcher creates and fills the *mfxfInitializationParam* structure according to mfxConfig values set by an application. Calling this function directly is not recommended. Instead, applications must call the mfxCreateSession function.

Since This function is available since API version 2.0.

Parameters

- **par** – [in] *mfXInitializationParam* structure that indicates the minimum library version and acceleration type.
- **session** – [out] Pointer to the session handle.

Returns

MFX_ERR_NONE The function completed successfully. The output parameter contains the handle of the session.

MFX_ERR_UNSUPPORTED The function cannot find the desired implementation or version.

Important: The *MFXInitialize()* function is mandatory for any implementation.

MFXClose

mfXStatus **MFXClose**(*mfXSession* session)

Completes and deinitializes a session. Any active tasks in execution or in queue are aborted. The application cannot call any API function after calling this function.

All child sessions must be disjoined before closing a parent session.

Since This function is available since API version 1.0.

Parameters **session** – [in] session handle.

Returns **MFX_ERR_NONE** The function completed successfully.

Important: The *MFXClose()* function is mandatory for any implementation.

MFXQueryIMPL

mfXStatus **MFXQueryIMPL**(*mfXSession* session, *mfXIMPL* *impl)

Returns the implementation type of a given session.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **impl** – [out] Pointer to the implementation type

Returns **MFX_ERR_NONE** The function completed successfully.

MFxQueryVersion

mfXStatus **MFxQueryVersion**(*mfXSession* session, *mfXVersion* *version)

Returns the implementation version.

Since This function is available since API version 1.0.

Parameters

- **session** – [in] Session handle.
- **version** – [out] Pointer to the returned implementation version.

Returns MFX_ERR_NONE The function completed successfully.

MFxJoinSession

mfXStatus **MFxJoinSession**(*mfXSession* session, *mfXSession* child)

Joins the child session to the current session.

After joining, the two sessions share thread and resource scheduling for asynchronous operations. However, each session still maintains its own device manager and buffer/frame allocator. Therefore, the application must use a compatible device manager and buffer/frame allocator to share data between two joined sessions.

The application can join multiple sessions by calling this function multiple times. When joining the first two sessions, the current session becomes the parent responsible for thread and resource scheduling of any later joined sessions.

Joining of two parent sessions is not supported.

Since This function is available since API version 1.1.

Parameters

- **session** – [inout] The current session handle.
- **child** – [in] The child session handle to be joined

Returns

MFX_ERR_NONE The function completed successfully.

MFX_WRN_IN_EXECUTION Active tasks are executing or in queue in one of the sessions. Call this function again after all tasks are completed.

MFX_ERR_UNSUPPORTED The child session cannot be joined with the current session.

MFXDisjoinSession

mfxFStatus **MFXDisjoinSession**(*mfxFSession* session)

Removes the joined state of the current session.

After disjoining, the current session becomes independent. The application must
 ↪ ensure there **is** no active task running **in** the session before calling this API.
 ↪ function.

Since This function is available since API version 1.1.

Parameters **session** – [inout] The current session handle.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_WRN_IN_EXECUTION Active tasks are executing or in queue in one of the sessions.
 Call this function again after all tasks are completed.

MFX_ERR_UNDEFINED_BEHAVIOR The session is independent, or this session is the parent
 of all joined sessions.

MFXCloneSession

mfxFStatus **MFXCloneSession**(*mfxFSession* session, *mfxFSession* *clone)

Creates a clean copy of the current session.

The cloned session **is** an independent session **and** does **not** inherit **any** user-
 ↪ defined buffer, frame allocator, **or** device manager handles **from the** current.
 ↪ session.

This function **is** a light-weight equivalent of MFXJoinSession after MFXInit.

Since This function is available since API version 1.1.

Parameters

- **session** – [in] The current session handle.
- **clone** – [out] Pointer to the cloned session handle.

Returns MFX_ERR_NONE The function completed successfully.

MFXSetPriority

mfxStatus **MFXSetPriority**(*mfxSession* session, *mfxPriority* priority)

Sets the current session priority.

Since This function is available since API version 1.1.

Parameters

- **session** – [in] The current session handle.
- **priority** – [in] Priority value.

Returns MFX_ERR_NONE The function completed successfully.

MFXGetPriority

mfxStatus **MFXGetPriority**(*mfxSession* session, *mfxPriority* *priority)

Returns the current session priority.

Since This function is available since API version 1.1.

Parameters

- **session** – [in] The current session handle.
- **priority** – [out] Pointer to the priority value.

Returns MFX_ERR_NONE The function completed successfully.

Memory

Functions for internal memory allocation and management.

API

- *MFXMemory_GetSurfaceForVPP*
- *MFXMemory_GetSurfaceForVPPOut*
- *MFXMemory_GetSurfaceForEncode*
- *MFXMemory_GetSurfaceForDecode*

MFXMemory_GetSurfaceForVPP

mfxFStatus **MFXMemory_GetSurfaceForVPP**(*mfxFSession* session, *mfxFFrameSurface1* **surface)

Returns surface which can be used as input for VPP.

VPP should be initialized before this call. Surface should be released with `mfxFFrameSurface1::FrameInterface.Release(...)` after usage. The value of `mfxFFrameSurface1::Data.Locked` for the returned surface is 0.

Since This function is available since API version 2.0.

Parameters

- **session** – [in] Session handle.
- **surface** – [out] Pointer is set to valid *mfxFFrameSurface1* object.

Returns

- MFX_ERR_NONE The function completed successfully.
- MFX_ERR_NULL_PTR If double-pointer to the **surface** is NULL.
- MFX_ERR_INVALID_HANDLE If **session** was not initialized.
- MFX_ERR_NOT_INITIALIZED If VPP was not initialized (allocator needs to know surface size from somewhere).
- MFX_ERR_MEMORY_ALLOC In case of any other internal allocation error.
- MFX_WRN_ALLOC_TIMEOUT_EXPIRED In case of waiting timeout expired (if set with *mfxFExtAllocationHints*).

Alias below, can be used as well:

MFXMemory_GetSurfaceForVPPIn

Alias for `MFXMemory_GetSurfaceForVPP` function.

MFXMemory_GetSurfaceForVPPOut

mfxFStatus **MFXMemory_GetSurfaceForVPPOut**(*mfxFSession* session, *mfxFFrameSurface1* **surface)

Returns surface which can be used as output of VPP.

VPP should be initialized before this call. Surface should be released with `mfxFFrameSurface1::FrameInterface.Release(...)` after usage. The value of `mfxFFrameSurface1::Data.Locked` for the returned surface is 0.

Since This function is available since API version 2.1.

Parameters

- **session** – [in] Session handle.
- **surface** – [out] Pointer is set to valid *mfxFFrameSurface1* object.

Returns

- MFx_ERR_NONE The function completed successfully.
- MFx_ERR_NULL_PTR If double-pointer to the `surface` is NULL.
- MFx_ERR_INVALID_HANDLE If `session` was not initialized.
- MFx_ERR_NOT_INITIALIZED If VPP was not initialized (allocator needs to know surface size from somewhere).
- MFx_ERR_MEMORY_ALLOC In case of any other internal allocation error.
- MFx_WRN_ALLOC_TIMEOUT_EXPIRED In case of waiting timeout expired (if set with *mfExtAllocationHints*).

MFxMemory_GetSurfaceForEncode

mfStatus **MFxMemory_GetSurfaceForEncode**(*mfSession* session, *mfFrameSurface1* **surface)

Returns a surface which can be used as input for the encoder.

Encoder should be initialized before this call. Surface should be released with `mfFrameSurface1::FrameInterface.Release(...)` after usage. The value of `mfFrameSurface1::Data.Locked` for the returned surface is 0.

Since This function is available since API version 2.0.

Parameters

- **session** – [in] Session handle.
- **surface** – [out] Pointer is set to valid *mfFrameSurface1* object.

Returns

- MFx_ERR_NONE The function completed successfully.
- MFx_ERR_NULL_PTR If surface is NULL.
- MFx_ERR_INVALID_HANDLE If session was not initialized.
- MFx_ERR_NOT_INITIALIZED If the encoder was not initialized (allocator needs to know surface size from somewhere).
- MFx_ERR_MEMORY_ALLOC In case of any other internal allocation error.
- MFx_WRN_ALLOC_TIMEOUT_EXPIRED In case of waiting timeout expired (if set with *mfExtAllocationHints*).

MFxMemory_GetSurfaceForDecode

mfStatus **MFxMemory_GetSurfaceForDecode**(*mfSession* session, *mfFrameSurface1* **surface)

Returns a surface which can be used as output of the decoder.

Decoder should be initialized before this call. Surface should be released with `mfFrameSurface1::FrameInterface.Release(...)` after usage. The value of `mfFrameSurface1::Data.Locked` for the returned surface is 0.

Since This function is available since API version 2.0.

Note: This function was added to simplify transition from legacy surface management to the proposed internal allocation approach. Previously, the user allocated surfaces for the working pool and fed them to the decoder using `DecodeFrameAsync` calls. With `MFXMemory_GetSurfaceForDecode` it is possible to change the existing pipeline by just changing the source of work surfaces. Newly developed applications should prefer direct usage of `DecodeFrameAsync` with internal allocation.

Parameters

- **session** – [in] Session handle.
- **surface** – [out] Pointer is set to valid *mfxFrameSurface1* object.

Returns

`MFX_ERR_NONE` The function completed successfully.

`MFX_ERR_NULL_PTR` If surface is NULL.

`MFX_ERR_INVALID_HANDLE` If session was not initialized.

`MFX_ERR_NOT_INITIALIZED` If the decoder was not initialized (allocator needs to know surface size from somewhere).

`MFX_ERR_MEMORY_ALLOC` Other internal allocation error.

`MFX_WRN_ALLOC_TIMEOUT_EXPIRED` In case of waiting timeout expired (if set with *mfxExtAllocationHints*).

Implementation Capabilities

Functions to report capabilities of available implementations and create user-requested library implementations.

API

- *MFXQueryImplsDescription*
- *MFXReleaseImplDescription*

MFXQueryImplsDescription

mfxHDL ***MFXQueryImplsDescription**(*mfxImplCapsDeliveryFormat* format, *mfxU32* *num_impls)
Delivers implementation capabilities in the requested format according to the format value.

Since This function is available since API version 2.0.

Parameters

- **format** – [in] Format in which capabilities must be delivered. See `mfxImplCapsDeliveryFormat` for more details.
- **num_impls** – [out] Number of the implementations.

Returns Array of handles to the capability report or NULL in case of unsupported format or NULL num_impls pointer. Length of array is equal to num_impls.

Important: The *MFXQueryImplsDescription()* function is mandatory for any implementation.

MFXReleaseImplDescription

mfxStatus **MFXReleaseImplDescription**(*mfxHDL* hdl)

Destroys the handle allocated by the MFXQueryImplsDescription function. Implementation must remember which handles are released. Once the last handle is released, this function must release memory allocated for the array of handles.

Since This function is available since API version 2.0.

Parameters **hdl** – [in] Handle to destroy. Can be equal to NULL.

Returns MFX_ERR_NONE The function completed successfully.

Important: The *MFXReleaseImplDescription()* function is mandatory for any implementation.

Adapters

Functions that identify graphics adapters for Microsoft* DirectX* video processing, encoding, and decoding.

API

- *MFXQueryAdapters*
- *MFXQueryAdaptersDecode*
- *MFXQueryAdaptersNumber*

MFXQueryAdapters

mfxStatus **MFXQueryAdapters**(*mfxComponentInfo* *input_info, *mfxAdaptersInfo* *adapters)

Returns a list of adapters that are suitable to handle workload **input_info**. The list is sorted in priority order, with iGPU given the highest precedence. This rule may change in the future. If the **input_info** pointer is NULL, the list of all available adapters will be returned.

Since This function is available since API version 1.31.

Parameters

- **input_info** – [in] Pointer to workload description. See *mfxCComponentInfo* description for details.
- **adapters** – [out] Pointer to output description of all suitable adapters for input workload. See *mfxADaptersInfo* description for details.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_NULL_PTR `input_info` or `adapters` pointer is NULL.

MFX_ERR_NOT_FOUND No suitable adapters found.

MFX_WRN_OUT_OF_RANGE Not enough memory to report back entire list of adapters. In this case as many adapters as possible will be returned.

MFXQueryAdaptersDecode

mfxStatus **MFXQueryAdaptersDecode**(*mfxBitstream* *bitstream, *mfxU32* codec_id, *mfxADaptersInfo* *adapters)

Returns list of adapters that are suitable to decode the input bitstream. The list is sorted in priority order, with iGPU given the highest precedence. This rule may change in the future. This function is a simplification of `MFXQueryAdapters`, because `bitstream` is a description of the workload itself.

Since This function is available since API version 1.31.

Parameters

- **bitstream** – [in] Pointer to bitstream with input data.
- **codec_id** – [in] Codec ID to determine the type of codec for the input bitstream.
- **adapters** – [out] Pointer to the output list of adapters. Memory should be allocated by user. See *mfxADaptersInfo* description for details.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_NULL_PTR `bitstream` or `adapters` pointer is NULL.

MFX_ERR_NOT_FOUND No suitable adapters found.

MFX_WRN_OUT_OF_RANGE Not enough memory to report back entire list of adapters. In this case as many adapters as possible will be returned.

MFXQueryAdaptersNumber

mfxStatus **MFXQueryAdaptersNumber**(*mfxU32* *num_adapters)

Returns the number of detected graphics adapters. It can be used before calling `MFXQueryAdapters` to determine the size of input data that the user will need to allocate.

Since This function is available since API version 1.31.

Parameters `num_adapters` – [out] Pointer for the output number of detected graphics adapters.

Returns

- MFX_ERR_NONE The function completed successfully.
- MFX_ERR_NULL_PTR num_adapters pointer is NULL.

VideoDECODE_VPP

Functions that implement combined operation of decoding and video processing with multiple output frame surfaces.

API

- *MFXVideoDECODE_VPP_Init*
- *MFXVideoDECODE_VPP_Reset*
- *MFXVideoDECODE_VPP_GetChannelParam*
- *MFXVideoDECODE_VPP_DecodeFrameAsync*
- *MFXVideoDECODE_VPP_Close*

MFXVideoDECODE_VPP_Init

mfxStatus **MFXVideoDECODE_VPP_Init**(*mfxSession* session, *mfxVideoParam* *decode_par, *mfxVideoChannelParam* **vpp_par_array, *mfxU32* num_vpp_par)

Initialize the SDK in (decode + vpp) mode. The logic of this function is similar to *MFXVideoDECODE_Init*, but application has to provide array of pointers to *mfxVideoChannelParam* and num_channel_param - number of channels. Application is responsible for

memory allocation for *mfxVideoChannelParam* parameters and for each channel it should specify channel IDs:

mfxVideoChannelParam::mfxFrameInfo::ChannelId. ChannelId should be unique value within one session. ChannelID equals to the 0 is reserved for the original decoded frame. The application can attach *mfxExtInCrops* to *mfxVideoChannelParam::ExtParam* to annotate input video frame if it wants to enable letterboxing operation.

Since This function is available since API version 2.1.

Parameters

- **session** – [in] SDK session handle.
- **decode_par** – [in] Pointer to the *mfxVideoParam* structure which contains initialization parameters for decoder.
- **vpp_par_array** – [in] Array of pointers to *mfxVideoChannelParam* structures. Each *mfxVideoChannelParam* contains initialization parameters for each VPP channel.
- **num_vpp_par** – [in] Size of array of pointers to *mfxVideoChannelParam* structures.

Returns

- MFX_ERR_NONE The function completed successfully.

MFX_ERR_INVALID_VIDEO_PARAM The function detected invalid video parameters. These parameters may be out of the valid range, or the combination of them resulted in incompatibility. Incompatibility not resolved.

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved.

MFX_ERR_UNDEFINED_BEHAVIOR The component is already initialized.

MFX_WRN_FILTER_SKIPPED The VPP skipped one or more filters requested by the application.

Important: The `MFXVideoDECODE_VPP_Init()` is mandatory when implementing a combined decode plus vpp.

MFXVideoDECODE_VPP_Reset

mfxfStatus **MFXVideoDECODE_VPP_Reset**(*mfxfSession* session, *mfxfVideoParam* *decode_par, *mfxfVideoChannelParam* **vpp_par_array, *mfxfU32* num_vpp_par)

This function is similar to `MFXVideoDECODE_Reset` and stops the current decoding and vpp operation, and restores internal structures or parameters for a new decoding plus vpp operation. It resets the state of the decoder and/or all initialized vpp channels. Applications have to care about draining of buffered frames for decode and all vpp channels before call this function. The application can attach `mfxfExtInCrops` to `mfxfVideoChannelParam::ExtParam` to annotate input video frame if it wants to enable letterboxing operation.

Since This function is available since API version 2.1.

Parameters

- **session** – [in] Session handle.
- **decode_par** – [in] Pointer to the `mfxfVideoParam` structure which contains new initialization parameters for decoder. Might be NULL if application wants to Reset only VPP channels.
- **vpp_par_array** – [in] Array of pointers to `mfxfVideoChannelParam` structures. Each `mfxfVideoChannelParam` contains new initialization parameters for each VPP channel.
- **num_vpp_par** – [in] Size of array of pointers to `mfxfVideoChannelParam` structures.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_INVALID_VIDEO_PARAM The function detected that video parameters are wrong or they conflict with initialization parameters. Reset is impossible.

MFX_ERR_INCOMPATIBLE_VIDEO_PARAM The function detected that video parameters provided by the application are incompatible with initialization parameters. Reset requires additional memory allocation and cannot be executed. The application should close the component and then reinitialize it.

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM The function detected some video parameters were incompatible with others; incompatibility resolved. **MFX_ERR_NULL_PTR** Both pointers `decode_par` and `vpp_par_array` equal to zero.

MFXVideoDECODE_VPP_GetChannelParam

mfxfStatus **MFXVideoDECODE_VPP_GetChannelParam**(*mfxfSession* session, *mfxfVideoChannelParam* *par, *mfxfU32* channel_id)

Returns actual VPP parameters for selected channel which should be specified by application through *mfxfVideoChannelParam::mfxfFrameInfo::ChannelId*.

Since This function is available since API version 2.1.

Parameters

- **session** – [in] Session handle.
- **par** – [in] Pointer to the *mfxfVideoChannelParam* structure which allocated by application
- **channel_id** – [in] specifies the requested channel's info

Returns

- MFX_ERR_NONE The function completed successfully.
- MFX_ERR_NULL_PTR par pointer is NULL.
- MFX_ERR_NOT_FOUND the library is not able to find VPP channel with such channel_id.

MFXVideoDECODE_VPP_DecodeFrameAsync

mfxfStatus **MFXVideoDECODE_VPP_DecodeFrameAsync**(*mfxfSession* session, *mfxfBitstream* *bs, *mfxfU32* *skip_channels, *mfxfU32* num_skip_channels, *mfxfSurfaceArray* **surf_array_out)

This function is similar to *MFXVideoDECODE_DecodeFrameAsync* and inherits all bitstream processing logic. As output, it allocates and returns *surf_array_out* array of processed surfaces according to the chain of filters specified by application in *MFXVideoDECODE_VPP_Init*, including original decoded frames. In the *surf_array_out*, the original decoded frames are returned through surfaces with *mfxfFrameInfo::ChannelId* == 0, followed by each of the subsequent frame surfaces for each of the requested *mfxfVideoChannelParam* entries provided to the *MFXVideoCECODE_VPP_Init* function. At maximum, the number of frame surfaces return is 1 + the value of *num_vpp_par* to the *MFXVideoDECODE_VPP_Init* function, but the application must be prepared to the case when some particular filters are not ready to output surfaces, so the length of *surf_array_out* will be less. Application should use *mfxfFrameInfo::ChannelId* parameter to match output surface against configured filter.

An application must synchronize each output surface from the *surf_array_out* surface array independently.

Since This function is available since API version 2.1.

Parameters

- **session** – [in] SDK session handle.
- **bs** – [in] Pointer to the input bitstream.
- **skip_channels** – [in] Pointer to the array of *ChannelIds* which specifies channels with skip output frames. Memory for the array is allocated by application.
- **num_skip_channels** – [in] Number of channels addressed by *skip_channels*.

- **surf_array_out** – [out] The address of a pointer to the structure with frame surfaces.

Returns

MFX_ERR_NONE The function completed successfully and the output surface is ready for decoding.

MFX_ERR_MORE_DATA The function requires more bitstream at input before decoding can proceed.

MFX_ERR_MORE_SURFACE The function requires more frame surface at output before decoding can proceed.

MFX_ERR_DEVICE_LOST Hardware device was lost.

See the *Working with Microsoft* DirectX* Applications section* for further information.

MFX_WRN_DEVICE_BUSY Hardware device is currently busy. Call this function again after `MFXVideoCORE_SyncOperation` or in a few milliseconds.

MFX_WRN_VIDEO_PARAM_CHANGED The decoder detected a new sequence header in the bitstream. Video parameters may have changed.

MFX_ERR_INCOMPATIBLE_VIDEO_PARAM The decoder detected incompatible video parameters in the bitstream and failed to follow them.

MFX_ERR_NULL_PTR `num_skip_channels` doesn't equal to 0 when `skip_channels` is NULL.

Important: The `MFXVideoDECODE_VPP_DecodeFrameAsync()` is mandatory when implementing a combined decode plus vpp.

MFXVideoDECODE_VPP_Close

mfxStatus **MFXVideoDECODE_VPP_Close**(*mfxSession* session)

This function is similar to `MFXVideoDECODE_Close`. It terminates the current decoding and vpp operation and de-allocates any internal tables or structures.

Since This function is available since API version 2.1.

Parameters **session** – [in] Session handle.

Returns **MFX_ERR_NONE** The function completed successfully.

Important: The `MFXVideoDECODE_VPP_Close()` is mandatory when implementing a combined decode plus vpp.

10.5.2 Structure Reference

Type Definitions Structures used for type definitions.

Memory Structures Structures used for memory.

Implementation Management Structures used for implementation management.

Cross-component Structures Structures used across library components.

Decode Structures Structures used by Decode only.

Encode Structures Structures used by Encode only.

VPP Structures Structures used by VPP only.

Protected Structures Protected structures.

DECODDE_VPP Structures Structures used by *DECODDE_VPP* only.

Camera Structures Structures used by Camera Raw Acceleration Processing.

Type Definitions

Structures used for type definitions.

API

- *mfExtBuffer*
- *mfHDLPair*
- *mfI16Pair*
- *mfRange32U*
- *mfStructVersion*

mfExtBuffer

struct **mfExtBuffer**

The common header definition for external buffers and video processing hints.

Public Members

mfU32 **BufferId**

Identifier of the buffer content. See the ExtendedBufferID enumerator for a complete list of extended buffers.

mfU32 **BufferSz**

Size of the buffer.

mfxDLPair

struct **mfxDLPair**
Represents pair of handles of type mfxHDL.

Public Members

mfxHDL **first**
First handle.

mfxHDL **second**
Second handle.

mfxI16Pair

struct **mfxI16Pair**
Represents a pair of numbers of type mfxI16.

Public Members

mfxI16 **x**
First number.

mfxI16 **y**
Second number.

mfxRange32U

struct **mfxRange32U**
Represents a range of unsigned values.

Public Members

mfxU32 **Min**
Minimal value of the range.

mfxU32 **Max**
Maximal value of the range.

mfxU32 **Step**
Value increment.

mfStructVersion

union **mfStructVersion**

#include <mfdefs.h> Introduce the field Version for any structure. Assumed that any structure changes are backward binary compatible. *mfStructVersion* starts from {1,0} for any new API structures. If *mfStructVersion* is added to the existent legacy structure (replacing reserved fields) it starts from {1, 1}.

Major and Minor fields

Anonymous structure with Major and Minor fields. Minor number is incremented when reserved fields are used. Major number is incremented when the size of structure is increased.

mfU8 **Minor**

Minor number of the correspondent structure.

mfU8 **Major**

Major number of the correspondent structure.

Public Members

struct *mfStructVersion::*[anonymous] [**anonymous**]

mfU16 **Version**

Structure version number.

Memory Structures

Structures used for memory.

API

- *mfBitstream*
- *mfFrameAllocator*
- *mfFrameAllocRequest*
- *mfFrameAllocResponse*
- *mfFrameData*
- *mfFrameInfo*
- *mfFrameSurface1*
- *mfFrameSurfaceInterface*
- *mfSurfacePoolInterface*

mfxBitstream

struct **mfxBitstream**

Defines the buffer that holds compressed video data.

Public Members

mfxEncryptedData ***EncryptedData**

Reserved and must be zero.

mfxExtBuffer ****ExtParam**

Array of extended buffers for additional bitstream configuration. See the `ExtendedBufferID` enumerator for a complete list of extended buffers.

mfxU16 **NumExtParam**

The number of extended buffers attached to this structure.

mfxU32 **CodecId**

Specifies the codec format identifier in the FourCC code. See the `CodecFormatFourCC` enumerator for details. This optional parameter is required for the simplified decode initialization.

mfxI64 **DecodeTimeStamp**

Decode time stamp of the compressed bitstream in units of 90KHz. A value of `MFX_TIMESTAMP_UNKNOWN` indicates that there is no time stamp.

This value is calculated by the encoder from the presentation time stamp provided by the application in the *mfxFrameSurface1* structure and from the frame rate provided by the application during the encoder initialization.

mfxU64 **TimeStamp**

Time stamp of the compressed bitstream in units of 90KHz. A value of `MFX_TIMESTAMP_UNKNOWN` indicates that there is no time stamp.

mfxU8 ***Data**

Bitstream buffer pointer, 32-bytes aligned.

mfxU32 **DataOffset**

Next reading or writing position in the bitstream buffer.

mfxU32 **DataLength**

Size of the actual bitstream data in bytes.

mfxU32 **MaxLength**

Allocated bitstream buffer size in bytes.

mfxU16 **PicStruct**

Type of the picture in the bitstream. Output parameter.

mfxU16 **FrameType**

Frame type of the picture in the bitstream. Output parameter.

mfxU16 DataFlag

Indicates additional bitstream properties. See the `BitstreamDataFlag` enumerator for details.

mfxU16 reserved2

Reserved for future use.

mfxFrameAllocator**struct mfxFrameAllocator**

Describes the API callback functions `Alloc`, `Lock`, `Unlock`, `GetHDL`, and `Free` that the implementation might use for allocating internal frames. Applications that operate on OS-specific video surfaces must implement these API callback functions.

Using the default allocator implies that frame data passes in or out of functions through pointers, as opposed to using memory IDs.

Behavior is undefined when using an incompletely defined external allocator. See the [Memory Allocation and External Allocators section](#) for additional information.

Public Members***mfxHDL pthis***

Pointer to the allocator object.

mfxStatus (*Alloc)(mfxHDL pthis, mfxFrameAllocRequest *request, mfxFrameAllocResponse *response)

Allocates surface frames. For decoders, `MFVideoDECODE_Init` calls `Alloc` only once. That call includes all frame allocation requests. For encoders, `MFVideoENCODE_Init` calls `Alloc` twice: once for the input surfaces and again for the internal reconstructed surfaces.

If two library components must share DirectX* surfaces, this function should pass the pre-allocated surface chain to the library instead of allocating new DirectX surfaces. See the [Surface Pool Allocation section](#) for additional information.

Parameters

- **pthis** – [in] Pointer to the allocator object.
- **request** – [in] Pointer to the `mfxFrameAllocRequest` structure that specifies the type and number of required frames.
- **response** – [out] Pointer to the `mfxFrameAllocResponse` structure that retrieves frames actually allocated.

Returns

`MF_ERR_NONE` The function successfully allocated the memory block.

`MF_ERR_MEMORY_ALLOC` The function failed to allocate the video frames.

`MF_ERR_UNSUPPORTED` The function does not support allocating the specified type of memory.

mfxStatus (*Lock)(mfxHDL pthis, mfxMemId mid, mfxFrameData *ptr)

Locks a frame and returns its pointer.

Parameters

- **pthis** – [in] Pointer to the allocator object.
- **mid** – [in] Memory block ID.
- **ptr** – [out] Pointer to the returned frame structure.

Returns

MFX_ERR_NONE The function successfully locked the memory block.
 MFX_ERR_LOCK_MEMORY This function failed to lock the frame.

mfxStatus (***Unlock**)(*mfxHDL* pthis, *mfxMemId* mid, *mfxFrameData* *ptr)

Unlocks a frame and invalidates the specified frame structure.

Parameters

- **pthis** – [in] Pointer to the allocator object.
- **mid** – [in] Memory block ID.
- **ptr** – [out] Pointer to the frame structure. This pointer can be NULL.

Returns MFX_ERR_NONE The function successfully locked the memory block.

mfxStatus (***GetHDL**)(*mfxHDL* pthis, *mfxMemId* mid, *mfxHDL* *handle)

Returns the OS-specific handle associated with a video frame. If the handle is a COM interface, the reference counter must increase. The library will release the interface afterward.

Parameters

- **pthis** – [in] Pointer to the allocator object.
- **mid** – [in] Memory block ID.
- **handle** – [out] Pointer to the returned OS-specific handle.

Returns

MFX_ERR_NONE The function successfully returned the OS-specific handle.
 MFX_ERR_UNSUPPORTED The function does not support obtaining OS-specific handle..

mfxStatus (***Free**)(*mfxHDL* pthis, *mfxFrameAllocResponse* *response)

De-allocates all allocated frames.

Parameters

- **pthis** – [in] Pointer to the allocator object.
- **response** – [in] Pointer to the *mfxFrameAllocResponse* structure returned by the Alloc function.

Returns MFX_ERR_NONE The function successfully de-allocated the memory block.

mfxfFrameAllocRequest

struct **mfxfFrameAllocRequest**

Describes multiple frame allocations when initializing encoders, decoders, and video preprocessors. A range specifies the number of video frames. Applications are free to allocate additional frames. In all cases, the minimum number of frames must be at least NumFrameMin or the called API function will return an error.

Public Members

mfxfU32 **AllocId**

Unique (within the session) ID of component requested the allocation.

mfxfFrameInfo **Info**

Describes the properties of allocated frames.

mfxfU16 **Type**

Allocated memory type. See the ExtMemFrameType enumerator for details.

mfxfU16 **NumFrameMin**

Minimum number of allocated frames.

mfxfU16 **NumFrameSuggested**

Suggested number of allocated frames.

mfxfFrameAllocResponse

struct **mfxfFrameAllocResponse**

Describes the response to multiple frame allocations. The calling API function returns the number of video frames actually allocated and pointers to their memory IDs.

Public Members

mfxfU32 **AllocId**

Unique (within the session) ID of component requested the allocation.

mfxfMemId ***mids**

Pointer to the array of the returned memory IDs. The application allocates or frees this array.

mfxfU16 **NumFrameActual**

Number of frames actually allocated.

mfxFrameData

struct **mfxY410**
Specifies “pixel” in Y410 color format.

Public Members

mfxU32 **U**
U component.

mfxU32 **Y**
Y component.

mfxU32 **V**
V component.

mfxU32 **A**
A component.

struct **mfxY416**
Specifies “pixel” in Y416 color format.

Public Members

mfxU32 **U**
U component.

mfxU32 **Y**
Y component.

mfxU32 **V**
V component.

mfxU32 **A**
A component.

struct **mfxA2RGB10**
Specifies “pixel” in A2RGB10 color format

Public Members

mfXU32 **B**
B component.

mfXU32 **G**
G component.

mfXU32 **R**
R component.

mfXU32 **A**
A component.

struct **mfXFrameData**
Describes frame buffer pointers.

Extension Buffers

mfXU16 **NumExtParam**
The number of extra configuration structures attached to this structure.

General members

mfXU16 **reserved**[9]
Reserved for future use.

mfXU16 **MemType**
Allocated memory type. See the ExtMemFrameType enumerator for details. Used for better integration of 3rd party plugins into the pipeline.

mfXU16 **PitchHigh**
Distance in bytes between the start of two consecutive rows in a frame.

mfXU64 **TimeStamp**
Time stamp of the video frame in units of 90KHz. Divide TimeStamp by 90,000 (90 KHz) to obtain the time in seconds. A value of MFX_TIMESTAMP_UNKNOWN indicates that there is no time stamp.

mfXU32 **FrameOrder**
Current frame counter for the top field of the current frame. An invalid value of MFX_FRAMEORDER_UNKNOWN indicates that API functions that generate the frame output do not use this frame.

mfXU16 **Locked**
Counter flag for the application. If Locked is greater than zero then the application locks the frame or field pair. Do not move, alter or delete the frame.

Color Planes

Data pointers to corresponding color channels (planes). The frame buffer pointers must be 16-byte aligned. The application has to specify pointers to all color channels even for packed formats. For example, for YUY2 format the application must specify Y, U, and V pointers. For RGB32 format, the application must specify R, G, B, and A pointers.

*mfxU8 *A*
A channel.

mfxMemId MemId
Memory ID of the data buffers. Ignored if any of the preceding data pointers is non-zero.

Additional Flags

mfxU16 Corrupted
Some part of the frame or field pair is corrupted. See the Corruption enumerator for details.

mfxU16 DataFlag
Additional flags to indicate frame data properties. See the FrameDataFlag enumerator for details.

Public Members

*mfxExtBuffer **ExtParam*
Points to an array of pointers to the extra configuration structures. See the ExtendedBufferID enumerator for a list of extended configurations.

mfxU16 PitchLow
Distance in bytes between the start of two consecutive rows in a frame.

*mfxU8 *Y*
Y channel.

*mfxU16 *Y16*
Y16 channel.

*mfxU8 *R*
R channel.

*mfxU8 *UV*
UV channel for UV merged formats.

*mfxU8 *VU*
YU channel for VU merged formats.

*mfxU8 *CbCr*
CbCr channel for CbCr merged formats.

*mfxU8 *CrCb*
CrCb channel for CrCb merged formats.

*mfXU8 *Cb*
Cb channel.

*mfXU8 *U*
U channel.

*mfXU16 *U16*
U16 channel.

*mfXU8 *G*
G channel.

*mfXY410 *Y410*
T410 channel for Y410 format (merged AVYU).

*mfXY416 *Y416*
This format is a packed 16-bit representation that includes 16 bits of alpha.

*mfXU8 *Cr*
Cr channel.

*mfXU8 *V*
V channel.

*mfXU16 *V16*
V16 channel.

*mfXU8 *B*
B channel.

*mfXA2RGB10 *A2RGB10*
A2RGB10 channel for A2RGB10 format (merged ARGB).

*mfXABGR16FP *ABGRFP16*
ABGRFP16 channel for half float ARGB format (use this merged one due to no separate FP16 Alpha Channel).

mfXFrameInfo

struct **mfXFrameInfo**

Specifies properties of video frames. See also “Configuration Parameter Constraints” chapter.

ROI

The region of interest of the frame. Specify the display width and height in *mfxVideoParam*.

mfxU16 CropX
X coordinate.

mfxU16 CropY
Y coordinate.

mfxU16 CropW
Width in pixels.

mfxU16 CropH
Height in pixels.

FrameRate

Specify the frame rate with the following formula: $\text{FrameRateExtN} / \text{FrameRateExtD}$.

For encoding, frame rate must be specified. For decoding, frame rate may be unspecified (FrameRateExtN and FrameRateExtD are all zeros.) In this case, the frame rate is defaulted to 30 frames per second.

mfxU32 FrameRateExtN
Frame rate numerator.

mfxU32 FrameRateExtD
Frame rate denominator.

AspectRatio

AspectRatioW and AspectRatioH are used to specify the sample aspect ratio. If sample aspect ratio is explicitly defined by the standards (see Table 6-3 in the MPEG-2 specification or Table E-1 in the H.264 specification), AspectRatioW and AspectRatioH should be the defined values. Otherwise, the sample aspect ratio can be derived as follows:

- $\text{AspectRatioW} = \text{display_aspect_ratio_width} * \text{display_height}$
- $\text{AspectRatioH} = \text{display_aspect_ratio_height} * \text{display_width}$

For MPEG-2, the above display aspect ratio must be one of the defined values in Table 6-3 in the MPEG-2 specification. For H.264, there is no restriction on display aspect ratio values.

If both parameters are zero, the encoder uses the default value of sample aspect ratio.

mfxU16 AspectRatioW
Aspect Ratio for width.

mfxU16 AspectRatioH
Aspect Ratio for height.

Public Members

mfXU32 **reserved**[4]

Reserved for future use.

mfXU16 **ChannelId**

The unique ID of each VPP channel set by application. It's required that during Init/Reset application fills ChannelId for each *mfXVideoChannelParam* provided by the application and the SDK sets it back to the correspondent *mfXSurfaceArray::mfXFrameSurface1* to distinguish different channels. It's expected that surfaces for some channels might be returned with some delay so application has to use *mfXFrameInfo::ChannelId* to distinguish what returned surface belongs to what VPP channel. Decoder's initialization parameters are always sent through channel with *mfXFrameInfo::ChannelId* equals to zero. It's allowed to skip setting of decoder's parameters for simplified decoding procedure

mfXU16 **BitDepthLuma**

Number of bits used to represent luma samples.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfXU16 **BitDepthChroma**

Number of bits used to represent chroma samples.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfXU16 **Shift**

When the value is not zero, indicates that values of luma and chroma samples are shifted. Use BitDepthLuma and BitDepthChroma to calculate shift size. Use zero value to indicate absence of shift. See example data alignment below.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfXFrameId **FrameId**

Describes the view and layer of a frame picture.

mfXU32 **FourCC**

FourCC code of the color format. See the ColorFourCC enumerator for details.

mfXU16 **Width**

Width of the video frame in pixels. Must be a multiple of 16.

mfXU16 **Height**

Height of the video frame in pixels. Must be a multiple of 16 for progressive frame sequence and a multiple of 32 otherwise.

***mfxU64* BufferSize**

Size of frame buffer in bytes. Valid only for plain formats (when FourCC is P8). In this case, Width, Height, and crop values are invalid.

***mfxU16* PicStruct**

Picture type as specified in the PicStruct enumerator.

***mfxU16* ChromaFormat**

Color sampling method. Value is the same as that of ChromaFormatIdc. ChromaFormat is not defined if FourCC is zero.

Note: Example data alignment for Shift = 0:

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
Value	0	0	0	0	0	0	Valid data												

Example data alignment for Shift != 0:

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Value	Valid data										0	0	0	0	0	0

mfxFrameSurface1**struct mfxFrameSurface1**

Defines the uncompressed frames surface information and data buffers. The frame surface is in the frame or complementary field pairs of pixels up to four color-channels, in two parts: *mfxFrameInfo* and *mfxFrameData*.

Public Members

struct *mfxFramSurfaceInterface* ***FrameInterface**
Specifies interface to work with surface.

mfxFramInfo **Info**
Specifies surface properties.

mfxFramData **Data**
Describes the actual frame buffer.

mfxFramSurfaceInterface

struct **mfxFramSurfaceInterface**

Public Members

mfxHDL **Context**
The context of the memory interface. User should not touch (change, set, null) this pointer.

mfxStructVersion **Version**
The version of the structure.

mfxStatus (***AddRef**)(*mfxFramSurfaceI* *surface)
Increments the internal reference counter of the surface. The surface is not destroyed until the surface is released using the *mfxFramSurfaceInterface::Release* function. *mfxFramSurfaceInterface::AddRef* should be used each time a new link to the surface is created (for example, copy structure) for proper surface management.

Parameters **surface** – [in] Valid surface.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If surface is NULL.

MFX_ERR_INVALID_HANDLE If *mfxFramSurfaceInterface->Context* is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (***Release**)(*mfxFramSurfaceI* *surface)
Decrements the internal reference counter of the surface. *mfxFramSurfaceInterface::Release* should be called after using the *mfxFramSurfaceInterface::AddRef* function to add a surface or when allocation logic requires it. For example, call *mfxFramSurfaceInterface::Release* to release a surface obtained with the *GetSurfaceForXXX* function.

Parameters **surface** – [in] Valid surface.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If surface is NULL.

MFX_ERR_INVALID_HANDLE If `mfxFrameSurfaceInterface->Context` is invalid (for example NULL).

MFX_ERR_UNDEFINED_BEHAVIOR If Reference Counter of surface is zero before call.

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (*GetRefCounter)(*mfxFrameSurface1* *surface, *mfxU32* *counter)

Returns current reference counter of *mfxFrameSurface1* structure.

Parameters

- **surface** – [in] Valid surface.
- **counter** – [out] Sets counter to the current reference counter value.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If surface or counter is NULL.

MFX_ERR_INVALID_HANDLE If `mfxFrameSurfaceInterface->Context` is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (*Map)(*mfxFrameSurface1* *surface, *mfxU32* flags)

Sets pointers of `surface->Info.Data` to actual pixel data, providing read-write access.

In case of video memory, the surface with data in video memory becomes mapped to system memory. An application can map a surface for read access with any value of `mfxFrameSurface1::Data::Locked`, but can map a surface for write access only when `mfxFrameSurface1::Data::Locked` equals to 0.

Note: A surface allows shared read access, but exclusive write access. Consider the following cases:

- Map with Write or Read|Write flags. A request during active another read or write access returns `MFX_ERR_LOCK_MEMORY` error immediately, without waiting. `MFX_MAP_NOWAIT` does not impact behavior. This type of request does not lead to any implicit synchronizations.
- Map with Read flag. A request during active write access will wait for resource to become free, or exits immediately with error if `MFX_MAP_NOWAIT` flag was set. This request may lead to the implicit synchronization (with same logic as Synchronize call) waiting for surface to become ready to use (all dependencies should be resolved and upstream components finished writing to this surface).

It is guaranteed that read access will be acquired right after synchronization without allowing another thread to acquire this surface for writing.

If `MFX_MAP_NOWAIT` was set and the surface is not ready yet (for example the surface has unresolved data dependencies or active processing), the read access request exits immediately with error.

Read-write access with `MFX_MAP_READ_WRITE` provides exclusive simultaneous reading and writing access.

Note: Bitwise copying of *mfxFrameSurface1* object between map / unmap calls may result in having dangling data pointers in copies.

Parameters

- **surface** – [in] Valid surface.

- **flags** – [out] Specify mapping mode.
- **surface->Info.Data** – [out] Pointers set to actual pixel data.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If surface is NULL.

MFX_ERR_INVALID_HANDLE If mfxFrameSurfaceInterface->Context is invalid (for example NULL).

MFX_ERR_UNSUPPORTED If flags are invalid.

MFX_ERR_LOCK_MEMORY If user wants to map the surface for write and surface->Data.Locked does not equal to 0.

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (*Unmap)(mfxFrameSurface1 *surface)

Invalidates pointers of surface->Info.Data and sets them to NULL. In case of video memory, the underlying texture becomes unmapped after last reader or writer unmap.

Parameters

- **surface** – [in] Valid surface.
- **surface->Info.Data** – [out] Pointers set to NULL.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If surface is NULL.

MFX_ERR_INVALID_HANDLE If mfxFrameSurfaceInterface->Context is invalid (for example NULL).

MFX_ERR_UNSUPPORTED If surface is already unmapped.

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (*GetNativeHandle)(mfxFrameSurface1 *surface, mfxHDL *resource, mfxResourceType *resource_type)

Returns a native resource's handle and type. The handle is returned *as-is*, meaning that the reference counter of base resources is not incremented. The native resource is not detached from surface and the library still owns the resource. User must not destroy the native resource or assume that the resource will be alive after *mfxFrameSurfaceInterface::Release*.

Parameters

- **surface** – [in] Valid surface.
- **resource** – [out] Pointer is set to the native handle of the resource.
- **resource_type** – [out] Type of native resource. See mfxResourceType enumeration).

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If any of surface, resource or resource_type is NULL.

MFX_ERR_INVALID_HANDLE If any of surface, resource or resource_type is not valid object (no native resource was allocated).

MFX_ERR_UNSUPPORTED If surface is in system memory.

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (*GetDeviceHandle)(*mfxFrameSurface1* *surface, *mfxHDL* *device_handle, *mfxHandleType* *device_type)

Returns a device abstraction that was used to create that resource. The handle is returned *as-is*, meaning that the reference counter for the device abstraction is not incremented. The native resource is not detached from the surface and the library still has a reference to the resource. User must not destroy the device or assume that the device will be alive after *mfxFrameSurfaceInterface::Release*.

Parameters

- **surface** – [in] Valid surface.
- **device_handle** – [out] Pointer is set to the device which created the resource
- **device_type** – [out] Type of device (see *mfxHandleType* enumeration).

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If any of surface, device_handle or device_type is NULL.

MFX_ERR_INVALID_HANDLE If any of surface, resource or resource_type is not valid object (no native resource was allocated).

MFX_ERR_UNSUPPORTED If surface is in system memory.

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (*Synchronize)(*mfxFrameSurface1* *surface, *mfxU32* wait)

Guarantees readiness of both the data (pixels) and any frame's meta information (for example corruption flags) after a function completes.

Instead of *MFXVideoCORE_SyncOperation*, users may directly call the *mfxFrameSurfaceInterface::Synchronize* function after the corresponding Decode or VPP function calls (*MFXVideoDECODE_DecodeFrameAsync* or *MFXVideoVPP_RunFrameVPPAsync*). The prerequisites to call the functions are:

- The main processing functions return *MFX_ERR_NONE*.
- A valid *mfxFrameSurface1* object.

Parameters

- **surface** – [in] Valid surface.
- **wait** – [out] Wait time in milliseconds.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If surface is NULL.

MFX_ERR_INVALID_HANDLE If any of surface is not valid object .

MFX_WRN_IN_EXECUTION If the given timeout is expired and the surface is not ready.

MFX_ERR_ABORTED If the specified asynchronous function aborted due to data dependency on a previous asynchronous function that did not complete.

MFX_ERR_UNKNOWN Any internal error.

void (***OnComplete**)(*mfxStatus* sts)

The library calls the function after complete of associated video operation notifying the application that frame surface is ready.

It is expected that the function is low-intrusive designed otherwise it may impact performance.

Attention This is callback function and intended to be called by the library only.

Note: The library calls this callback only when this surface is used as the output surface.

Parameters **sts** – [in] The status of completed operation.

mfxStatus (***QueryInterface**)(*mfxFrameSurface1* *surface, *mfxGUID* guid, *mfxHDL* *iface)

Returns an interface defined by the GUID. If the returned interface is a reference counted object the caller should release the obtained interface to avoid memory leaks.

Parameters

- **surface** – [in] Valid surface.
- **guid** – [in] GUID of the requested interface.
- **iface** – [out] Interface.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If interface or surface is NULL.

MFX_ERR_UNSUPPORTED If requested interface is not supported.

MFX_ERR_NOT_IMPLEMENTED If requested interface is not implemented.

MFX_ERR_NOT_INITIALIZED If requested interface is not available (not created or already deleted).

MFX_ERR_UNKNOWN Any internal error.

mfxSurfacePoolInterface

struct **mfxSurfacePoolInterface**

Specifies the surface pool interface.

Public Members

mfxHDL Context

The context of the surface pool interface. User should not touch (change, set, null) this pointer.

mfxStatus (***AddRef**)(struct *mfxSurfacePoolInterface* *pool)

Increments the internal reference counter of the *mfxSurfacePoolInterface*. The *mfxSurfacePoolInterface* is not destroyed until the *mfxSurfacePoolInterface* is destroyed with *mfxSurfacePoolInterface::Release* function. *mfxSurfacePoolInterface::AddRef* should be used each time a new link to the *mfxSurfacePoolInterface* is created for proper management.

Parameters *pool* – [in] Valid pool.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If pool is NULL.

MFX_ERR_INVALID_HANDLE If *mfxSurfacePoolInterface->Context* is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (***Release**)(struct *mfxSurfacePoolInterface* *pool)

Decrements the internal reference counter of the *mfxSurfacePoolInterface*. *mfxSurfacePoolInterface::Release* should be called after using the *mfxSurfacePoolInterface::AddRef* function to add a *mfxSurfacePoolInterface* or when allocation logic requires it. For example, call *mfxSurfacePoolInterface::Release* to release a *mfxSurfacePoolInterface* obtained with the *mfxFrameSurfaceInterface::QueryInterface* function.

Parameters *pool* – [in] Valid pool.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If pool is NULL.

MFX_ERR_INVALID_HANDLE If *mfxSurfacePoolInterface->Context* is invalid (for example NULL).

MFX_ERR_UNDEFINED_BEHAVIOR If Reference Counter of *mfxSurfacePoolInterface* is zero before call.

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (***GetRefCounter**)(struct *mfxSurfacePoolInterface* *pool, *mfxU32* *counter)

Returns current reference counter of *mfxSurfacePoolInterface* structure.

Parameters

- **pool** – [in] Valid pool.
- **counter** – [out] Sets counter to the current reference counter value.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If pool or counter is NULL.

MFX_ERR_INVALID_HANDLE If `mfxFacePoolInterface->Context` is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxFacePoolInterface (***SetNumSurfaces**)(struct *mfxFacePoolInterface* *pool, *mfu32* num_surfaces)

The function should be called by oneVPL components or application to specify how many surfaces it will use concurrently. Internally, oneVPL allocates surfaces in the shared pool according to the component's policy set by `mfxFacePoolAllocationPolicy`. The exact moment of surfaces allocation is defined by the component and generally independent from that call.

Parameters

- **pool** – [in] Valid pool.
- **num_surfaces** – [in] The number of surfaces required by the component.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If pool is NULL.

MFX_ERR_INVALID_HANDLE If `mfxFacePoolInterface->Context` is invalid (for example NULL).

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM If pool has **MFX_ALLOCATION_UNLIMITED** or **MFX_ALLOCATION_LIMITED** policy.

MFX_ERR_UNKNOWN Any internal error.

mfxFacePoolInterface (***RevokeSurfaces**)(struct *mfxFacePoolInterface* *pool, *mfu32* num_surfaces)

The function should be called by oneVPL components when component is closed or reset and doesn't need to use pool more. It helps to manage memory accordingly and release redundant memory. Important to specify the same number of surfaces which is requested during `SetNumSurfaces` call, otherwise it may lead to the pipeline stalls.

Parameters

- **pool** – [in] Valid pool.
- **num_surfaces** – [in] The number of surfaces used by the component.

Returns

MFX_ERR_NONE If no error.

MFX_WRN_OUT_OF_RANGE If `num_surfaces` doesn't equal to `num_surfaces` requested during `SetNumSurfaces` call.

MFX_ERR_NULL_PTR If pool is NULL.

MFX_ERR_INVALID_HANDLE If `mfxFacePoolInterface->Context` is invalid (for example NULL).

MFX_WRN_INCOMPATIBLE_VIDEO_PARAM If pool has **MFX_ALLOCATION_UNLIMITED** or **MFX_ALLOCATION_LIMITED** policy.

MFX_ERR_UNKNOWN Any internal error.

mfxFacePoolInterface (***GetAllocationPolicy**)(struct *mfxFacePoolInterface* *pool, *mfxFacePoolAllocationPolicy* *policy)

Returns current allocation policy.

Parameters

- **pool** – [in] Valid pool.
- **policy** – [out] Sets policy to the current allocation policy value.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If pool or policy is NULL.

MFX_ERR_INVALID_HANDLE If mfxSurfacePoolInterface->Context is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (***GetMaximumPoolSize**)(struct *mfxSurfacePoolInterface* *pool, *mfxU32* *size)

Returns maximum pool size. In case of mfxPoolAllocationPolicy::MFX_ALLOCATION_UNLIMITED policy 0xFFFFFFFF will be returned.

Parameters

- **pool** – [in] Valid pool.
- **size** – [out] Sets size to the maximum pool size value.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If pool or size is NULL.

MFX_ERR_INVALID_HANDLE If mfxSurfacePoolInterface->Context is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (***GetCurrentPoolSize**)(struct *mfxSurfacePoolInterface* *pool, *mfxU32* *size)

Returns current pool size.

Parameters

- **pool** – [in] Valid pool.
- **size** – [out] Sets size to the current pool size value.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If pool or size is NULL.

MFX_ERR_INVALID_HANDLE If mfxSurfacePoolInterface->Context is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxHDL **reserved**[4]

Reserved for future use.

Implementation Management

Structures used for implementation management.

API

- *mfxAAdapterInfo*
- *mfxAAdaptersInfo*
- *mfxEExtThreadsParam*
- *mfXInitParam*
- *mfXPlatform*
- *mfXVersion*
- *mfxEExtDeviceAffinityMask*
- *mfXInitializationParam*

mfxAAdapterInfo

struct **mfxAAdapterInfo**

Contains a description of the graphics adapter for the Legacy mode.

Public Members

mfXPlatform **Platform**

Platform type description. See *mfXPlatform* for details.

mfXU32 **Number**

Value which uniquely characterizes media adapter. On Windows* this number can be used for initialization through DXVA interface (see [example](#)).

mfXAdaptersInfo

struct **mfXAdaptersInfo**

Contains description of all graphics adapters available on the current system.

Public Members

mfxAdapterInfo *Adapters

Pointer to array of *mfxAdapterInfo* structs allocated by user.

mfxU32 NumAlloc

Length of Adapters array.

mfxU32 NumActual

Number of Adapters entries filled by MFXQueryAdapters.

mfxExtThreadsParam

struct **mfxExtThreadsParam**

Specifies options for threads created by this session. Attached to the *mfxInitParam* structure during legacy Intel(r) Media SDK session initialization or to *mfxInitializationParam* by the dispatcher in MFXCreateSession function.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_THREADS_PARAM.

mfxU16 NumThread

The number of threads.

mfxI32 SchedulingType

Scheduling policy for all threads.

mfxI32 Priority

Priority for all threads.

mfxU16 reserved[55]

Reserved for future use.

mfxInitParam

struct **mfxInitParam**

Specifies advanced initialization parameters. A zero value in any of the fields indicates that the corresponding field is not explicitly specified.

Public Members

mfxmlmpl **Implementation**

Enumerator that indicates the desired legacy Intel(r) Media SDK implementation.

mfxmlversion **Version**

Structure which specifies minimum library version or zero, if not specified.

mfxmlu16 **ExternalThreads**

Desired threading mode. Value 0 means internal threading, 1 - external.

mfxmlbuffer ****ExtParam**

Points to an array of pointers to the extra configuration structures; see the ExtendedBufferID enumerator for a list of extended configurations.

mfxmlu16 **NumExtParam**

The number of extra configuration structures attached to this structure.

mfxmlu16 **GPUCopy**

Enables or disables GPU accelerated copying between video and system memory in legacy Intel(r) Media SDK components. See the GPUCopy enumerator for a list of valid values.

mfxmlplatform

struct **mfxmlplatform**

Contains information about hardware platform for the Legacy mode.

Public Members

mfxmlu16 **CodeName**

Microarchitecture code name. See the PlatformCodeName enumerator for a list of possible values.

mfxmlu16 **DeviceId**

Unique identifier of graphics device.

mfxmlu16 **MediaAdapterType**

Description of graphics adapter type. See the mfxmlMediaAdapterType enumerator for a list of possible values.

mfxmlu16 **reserved[13]**

Reserved for future use.

mfVersion

union **mfVersion**

#include <mfcommon.h> The *mfVersion* union describes the version of the implementation.

Major and Minor fields

Anonymous structure with Major and Minor fields.

mfU16 **Minor**

Minor number of the implementation.

mfU16 **Major**

Major number of the implementation.

Public Members

struct *mfVersion*::[anonymous] [**anonymous**]

mfU32 **Version**

Implementation version number.

mfExtDeviceAffinityMask

struct **mfExtDeviceAffinityMask**

The *mfExtDeviceAffinityMask* structure is used by the application to specify affinity mask for the device with given device ID. See *mfDeviceDescription* for the device ID definition and sub device indexes. If the implementation manages CPU threads for some purpose, the user can set the CPU thread affinity mask by using this structure with DeviceID set to “CPU”.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_DEVICE_AFFINITY_MASK.

mfChar **DeviceID**[MFX_STRFIELD_LEN]

Null terminated string with device ID. In case of CPU affinity mask it must be equal to “CPU”.

mfU32 **NumSubDevices**

Number of sub devices or threads in case of CPU in the mask.

mfU8 ***Mask**

Mask array. Every bit represents sub-device (or thread for CPU). “1” means execution is allowed. “0” means that execution is prohibited on this sub-device (or thread). Length of the array is equal to the: “NumSubDevices / 8” and rounded to the closest (from the right) integer. Bits order within each entry of the mask array is LSB: bit 0 holds data for sub device with index 0 and bit 8 for sub device with index 8. Index of sub device is defined by the *mfDeviceDescription* structure.

mfXInitializationParam

struct **mfXInitializationParam**

Specifies initialization parameters for API version starting from 2.0.

Public Members

mfXAccelerationMode **AccelerationMode**

Hardware acceleration stack to use. OS dependent parameter. Use VA for Linux*, DX* for Windows* or HDDL.

mfXU16 **DeviceCopy**

Enables or disables device's accelerated copying between device and host. See the GPUCopy enumerator for a list of valid values. This parameter is the equivalent of *mfXInitParam::GPUCopy*.

mfXU16 **reserved[2]**

Reserved for future use.

mfXU16 **NumExtParam**

The number of extra configuration structures attached to this structure.

mfXExtBuffer ****ExtParam**

Points to an array of pointers to the extra configuration structures; see the ExtendedBufferID enumerator for a list of extended configurations.

mfXU32 **VendorImplID**

Vendor specific number with given implementation ID. Represents the same field from *mfXImplDescription*.

mfXU32 **reserved2[3]**

Reserved for future use.

Cross-component Structures

Structures used across library components.

API

- *mfXComponentInfo*
- *mfXExtHEVCParam*
- *mfXExtJPEGHuffmanTables*
- *mfXExtJPEGQuantTables*
- *mfXExtMVCSeqDesc*
- *mfXExtMVCTargetViews*
- *mfXExtVideoSignalInfo*

- *mfExtVP9Param*
- *mfFrameId*
- *mfInfoMFX*
- *mfMVCOperationPoint*
- *mfMVCViewDependency*
- *mfPayload*
- *mfVideoParam*

- *mfExtHyperModeParam*
- *mfGUID*
- *mfExtAllocationHints*
- *mfRefInterface*
- *mfExtMasteringDisplayColourVolume*
- *mfExtContentLightLevelInfo*

mfComponentInfo

struct **mfComponentInfo**

Contains workload description, which is accepted by MFXQueryAdapters function.

Public Members

mfComponentType **Type**

Type of workload: Encode, Decode, VPP. See *mfComponentType* enumerator for values.

mfVideoParam **Requirements**

Detailed description of workload. See *mfVideoParam* for details.

mfExtHEVCParam

struct **mfExtHEVCParam**

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_HEVC_PARAM.

mfxU16 PicWidthInLumaSamples

Specifies the width of each coded picture in units of luma samples.

mfxU16 PicHeightInLumaSamples

Specifies the height of each coded picture in units of luma samples.

mfxU64 GeneralConstraintFlags

Additional flags to specify exact profile and constraints. See the GeneralConstraintFlags enumerator for values of this field.

mfxU16 SampleAdaptiveOffset

Controls SampleAdaptiveOffset encoding feature. See the SampleAdaptiveOffset enumerator for supported values (bit-ORed). Valid during encoder Init and Runtime.

mfxU16 LCUSize

Specifies largest coding unit size (max luma coding block). Valid during encoder Init.

mfxExtJPEGHuffmanTables

struct **mfxExtJPEGHuffmanTables**

Specifies Huffman tables. The application may specify up to 2 quantization table pairs for baseline process. The encoder assigns an ID to each table. That ID is equal to the table index in the DCTables and ACTables arrays. Table “0” is used for encoding of the Y component and table “1” is used for encoding of the U and V component. The application may specify only one table, in which case the table will be used for all components in the image. The following table illustrates this behavior.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_JPEG_HUFFMAN.

mfxU16 NumDCTable

Number of DC quantization table in DCTables array.

mfxU16 NumACTable

Number of AC quantization table in ACTables array.

mfxU8 Bits[16]

Number of codes for each code length.

mfxU8 Values[12]

List of the 8-bit symbol values.

Array of AC tables.

struct *mfExtJPEGHuffmanTables*::[anonymous] **DCTables**[4]
 Array of DC tables.

struct *mfExtJPEGHuffmanTables*::[anonymous] **ACTables**[4]
 List of the 8-bit symbol values.

Table ID	0	1
Number of tables		
0	Y, U, V	
1	Y	U, V

mfExtJPEGQuantTables

struct **mfExtJPEGQuantTables**

Specifies quantization tables. The application may specify up to 4 quantization tables. The encoder assigns an ID to each table. That ID is equal to the table index in the Qm array. Table “0” is used for encoding of the Y component, table “1” for the U component, and table “2” for the V component. The application may specify fewer tables than the number of components in the image. If two tables are specified, then table “1” is used for both U and V components. If only one table is specified then it is used for all components in the image. The following table illustrates this behavior.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_JPEG_QT.

mfU16 NumTable

Number of quantization tables defined in Qm array.

mfU16 Qm[4][64]

Quantization table values.

Table ID	0	1	2
Number of tables			
0	Y, U, V		
1	Y	U, V	
2	Y	U	V

mfExtMVCSeqDesc

struct **mfExtMVCSeqDesc**

Describes the MVC stream information of view dependencies, view identifiers, and operation points. See the ITU*-T H.264 specification chapter H.7.3.2.1.4 for details.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_MVC_SEQUENCE_DESCRIPTION.

mfU32 NumView

Number of views.

mfU32 NumViewAlloc

The allocated view dependency array size.

mfMVCViewDependency *View

Pointer to a list of the *mfMVCViewDependency*.

mfU32 NumViewId

Number of view identifiers.

mfU32 NumViewIdAlloc

The allocated view identifier array size.

mfU16 *ViewId

Pointer to the list of view identifier.

mfU32 NumOP

Number of operation points.

mfU32 NumOPAlloc

The allocated operation point array size.

mfMVCOperationPoint *OP

Pointer to a list of the *mfMVCOperationPoint* structure.

mfU16 NumRefsTotal

Total number of reference frames in all views required to decode the stream. This value is returned from the MFXVideoDECODE_Decodeheader function. Do not modify this value.

*mfExtMVC*TargetViews

struct *mfExtMVC*TargetViews

Configures views for the decoding output.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_MVC_TARGET_VIEWS.

mfU16 TemporalId

The temporal identifier to be decoded.

mfU32 NumView

The number of views to be decoded.

mfU16 ViewId[1024]

List of view identifiers to be decoded.

mfExtVideoSignalInfo

struct **mfExtVideoSignalInfo**

Defines the video signal information.

For H.264, see Annex E of the ISO/IEC 14496-10 specification for the definition of these parameters.

For MPEG-2, see section 6.3.6 of the ITU* H.262 specification for the definition of these parameters. The field VideoFullRange is ignored.

For VC-1, see section 6.1.14.5 of the SMPTE* 421M specification. The fields VideoFormat and VideoFullRange are ignored.

Note: If ColourDescriptionPresent is zero, the color description information (including ColourPrimaries, TransferCharacteristics, and MatrixCoefficients) does not present in the bitstream.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VIDEO_SIGNAL_INFO.

mfU16 VideoFormat

mfU16 VideoFullRange

mfU16 ColourDescriptionPresent

mfU16 ColourPrimaries

mfU16 TransferCharacteristics

mfU16 MatrixCoefficients

mfxExtVP9Param

struct **mfxExtVP9Param**

Structure attached to the *mfxVideoParam* structure. Extends the *mfxVideoParam* structure with VP9-specific parameters. Used by both decoder and encoder.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VP9_PARAM.

mfxU16 FrameWidth

Width of the coded frame in pixels.

mfxU16 FrameHeight

Height of the coded frame in pixels.

mfxU16 WriteIVFHeaders

Set this option to ON to make the encoder insert IVF container headers to the output stream. The NumFrame field of the IVF sequence header will be zero. It is the responsibility of the application to update the NumFrame field with the correct value. See the CodingOptionValue enumerator for values of this option.

mfxI16 QIndexDeltaLumaDC

Specifies an offset for a particular quantization parameter.

mfxI16 QIndexDeltaChromaAC

Specifies an offset for a particular quantization parameter.

mfxI16 QIndexDeltaChromaDC

Specifies an offset for a particular quantization parameter.

mfxU16 NumTileRows

Number of tile rows. Should be power of two. The maximum number of tile rows is 4, per the VP9 specification. In addition, the maximum supported number of tile rows may depend on the underlying library implementation.

Use the Query API function to check if a particular pair of values (NumTileRows, NumTileColumns) is supported. In VP9, tile rows have dependencies and cannot be encoded or decoded in parallel. Therefore, tile rows are always encoded by the library in serial mode (one-by-one).

mfxU16 NumTileColumns

Number of tile columns. Should be power of two. Restricted with maximum and minimum tile width in luma pixels, as defined in the VP9 specification (4096 and 256 respectively). In addition, the maximum supported number of tile columns may depend on the underlying library implementation.

Use the Query API function to check if a particular pair of values (NumTileRows, NumTileColumns) is supported. In VP9, tile columns do not have dependencies and can be encoded/decoded in parallel. Therefore, tile columns can be encoded by the library in both parallel and serial modes.

Parallel mode is automatically utilized by the library when NumTileColumns exceeds 1 and does not exceed the number of tile coding engines on the platform. In other cases, serial mode is used. Parallel mode is

capable of encoding more than 1 tile row (within limitations provided by VP9 specification and particular platform). Serial mode supports only tile grids 1xN and Nx1.

mfxFramelId

struct **mfxFramelId**

Describes the view and layer of a frame picture.

Public Members

mfxU16 **TemporalId**

The temporal identifier as defined in the annex H of the ITU*-T H.264 specification.

mfxU16 **PriorityId**

Reserved and must be zero.

mfxU16 **DependencyId**

Reserved for future use.

mfxU16 **QualityId**

Reserved for future use.

mfxU16 **ViewId**

The view identifier as defined in the annex H of the ITU-T H.264 specification.

mfxInfoMFX

struct **mfxInfoMFX**

Specifies configurations for decoding, encoding, and transcoding processes. A zero value in any of these fields indicates that the field is not explicitly specified.

Public Members

mfxU32 **reserved[7]**

Reserved for future use.

mfxU16 **LowPower**

Hint to enable low power consumption mode for encoders. See the CodingOptionValue enumerator for values of this option. Use the Query API function to check if this feature is supported.

mfxU16 **BRCParamMultiplier**

Specifies a multiplier for bitrate control parameters. Affects the following variables: InitialDelayInKB, BufferSizeInKB, TargetKbps, MaxKbps. If this value is not equal to zero, the encoder calculates BRC parameters as value * BRCParamMultiplier.

mfxFramelInfo **FrameInfo**

mfxFramelInfo structure that specifies frame parameters.

***mfXU32* CodecId**

Specifies the codec format identifier in the FourCC code; see the CodecFormatFourCC enumerator for details. This is a mandated input parameter for the QueryIOSurf and Init API functions.

***mfXU16* CodecProfile**

Specifies the codec profile; see the CodecProfile enumerator for details. Specify the codec profile explicitly or the API functions will determine the correct profile from other sources, such as resolution and bitrate.

***mfXU16* CodecLevel**

Codec level; see the CodecLevel enumerator for details. Specify the codec level explicitly or the functions will determine the correct level from other sources, such as resolution and bitrate.

***mfXU16* TargetUsage**

Target usage model that guides the encoding process; see the TargetUsage enumerator for details.

***mfXU16* GopPicSize**

Number of pictures within the current GOP (Group of Pictures); if GopPicSize = 0, then the GOP size is unspecified. If GopPicSize = 1, only I-frames are used. The following pseudo-code that shows how the library uses this parameter:

```
mfXU16 get_gop_sequence (...) {
    pos=display_frame_order;
    if (pos == 0)
        return MFX_FRAMETYPE_I | MFX_FRAMETYPE_IDR | MFX_FRAMETYPE_REF;

    If (GopPicSize == 1) // Only I-frames
        return MFX_FRAMETYPE_I | MFX_FRAMETYPE_REF;

    if (GopPicSize == 0)
        frameInGOP = pos; //Unlimited GOP
    else
        frameInGOP = pos%GopPicSize;

    if (frameInGOP == 0)
        return MFX_FRAMETYPE_I | MFX_FRAMETYPE_REF;

    if (GopRefDist == 1 || GopRefDist == 0) // Only I,P frames
        return MFX_FRAMETYPE_P | MFX_FRAMETYPE_REF;

    frameInPattern = (frameInGOP-1)%GopRefDist;
    if (frameInPattern == GopRefDist - 1)
        return MFX_FRAMETYPE_P | MFX_FRAMETYPE_REF;

    return MFX_FRAMETYPE_B;
}
```

***mfXU16* GopRefDist**

Distance between I- or P (or GPB) - key frames; if it is zero, the GOP structure is unspecified. Note: If GopRefDist = 1, there are no regular B-frames used (only P or GPB); if *mfXExtCodingOption3::GPB* is ON, GPB frames (B without backward references) are used instead of P.

***mfXU16* GopOptFlag**

ORs of the GopOptFlag enumerator indicate the additional flags for the GOP specification.

mfXU16 **IdrInterval**

For H.264, specifies IDR-frame interval in terms of I-frames. For example:

- If IdrInterval = 0, then every I-frame is an IDR-frame.
- If IdrInterval = 1, then every other I-frame is an IDR-frame.

For HEVC, if IdrInterval = 0, then only first I-frame is an IDR-frame. For example:

- If IdrInterval = 1, then every I-frame is an IDR-frame.
- If IdrInterval = 2, then every other I-frame is an IDR-frame.

For MPEG2, IdrInterval defines sequence header interval in terms of I-frames. For example:

- If IdrInterval = 0 (default), then the sequence header is inserted once at the beginning of the stream.
- If IdrInterval = N, then the sequence header is inserted before every Nth I-frame.

If GopPicSize or GopRefDist is zero, IdrInterval is undefined.

mfXU16 **InitialDelayInKB**

Initial size of the Video Buffering Verifier (VBV) buffer.

Note: In this context, KB is 1000 bytes and Kbps is 1000 bps.

mfXU16 **QPI**

Quantization Parameter (QP) for I-frames for constant QP mode (CQP). Zero QP is not valid and means that the default value is assigned by the library. Non-zero QPI might be clipped to supported QPI range.

Note: In the HEVC design, a further adjustment to QPs can occur based on bit depth. Adjusted QPI value = $QPI - (6 * (\text{BitDepthLuma} - 8))$ for BitDepthLuma in the range [8,14]. For HEVC_MAIN10, we minus $(6*(10-8)=12)$ on our side and continue.

Note: Default QPI value is implementation dependent and subject to change without additional notice in this document.

mfXU16 **Accuracy**

Specifies accuracy range in the unit of tenth of percent.

mfXU16 **BufferSizeInKB**

Represents the maximum possible size of any compressed frames.

mfXU16 **TargetKbps**

Constant bitrate TargetKbps. Used to estimate the targeted frame size by dividing the frame rate by the bitrate.

mfXU16 **QPP**

Quantization Parameter (QP) for P-frames for constant QP mode (CQP). Zero QP is not valid and means that the default value is assigned by the library. Non-zero QPP might be clipped to supported QPI range.

Note: In the HEVC design, a further adjustment to QPs can occur based on bit depth. Adjusted QPP value = $QPP - (6 * (\text{BitDepthLuma} - 8))$ for BitDepthLuma in the range [8,14]. For HEVC_MAIN10, we minus $(6*(10-8)=12)$ on our side and continue.

Note: Default QPP value is implementation dependent and subject to change without additional notice in this document.

mfxU16 **ICQQuality**

Used by the Intelligent Constant Quality (ICQ) bitrate control algorithm. Values are in the 1 to 51 range, where 1 corresponds the best quality.

mfxU16 **MaxKbps**

The maximum bitrate at which the encoded data enters the Video Buffering Verifier (VBV) buffer.

mfxU16 **QPB**

Quantization Parameter (QP) for B-frames for constant QP mode (CQP). Zero QP is not valid and means that the default value is assigned by the library. Non-zero QP might be clipped to supported QPB range.

Note: In the HEVC design, a further adjustment to QPs can occur based on bit depth. Adjusted QPB value = $QPB - (6 * (\text{BitDepthLuma} - 8))$ for BitDepthLuma in the range [8,14]. For HEVC_MAIN10, we minus $(6*(10-8)=12)$ on our side and continue.

Note: Default QPB value is implementation dependent and subject to change without additional notice in this document.

mfxU16 **Convergence**

Convergence period in the unit of 100 frames.

mfxU16 **NumSlice**

Number of slices in each video frame. Each slice contains one or more macro-block rows. If NumSlice equals zero, the encoder may choose any slice partitioning allowed by the codec standard. See also *mfxExtCodingOption2::NumMbPerSlice*.

mfxU16 **NumRefFrame**

Max number of all available reference frames (for AVC/HEVC, NumRefFrame defines DPB size). If NumRefFrame = 0, this parameter is not specified. See also NumRefActiveP, NumRefActiveBL0, and NumRefActiveBL1 in the *mfxExtCodingOption3* structure, which set a number of active references.

mfxU16 **EncodedOrder**

If not zero, specifies that ENCODE takes the input surfaces in the encoded order and uses explicit frame type control. The application must still provide GopRefDist and *mfxExtCodingOption2::BRefType* so the library can pack headers and build reference lists correctly.

mfxU16 **DecodedOrder**

For AVC and HEVC, used to instruct the decoder to return output frames in the decoded order. Must be

zero for all other decoders. When enabled, correctness of *mfxFramData::TimeStamp* and *FrameOrder* for output surface is not guaranteed, the application should ignore them.

mfxU16 **ExtendedPicStruct**

Instructs DECODE to output extended picture structure values for additional display attributes. See the *PicStruct* description for details.

mfxU16 **TimeStampCalc**

Time stamp calculation method. See the *TimeStampCalc* description for details.

mfxU16 **SliceGroupsPresent**

Nonzero value indicates that slice groups are present in the bitstream. Used only by AVC decoder.

mfxU16 **MaxDecFrameBuffering**

Nonzero value specifies the maximum required size of the decoded picture buffer in frames for AVC and HEVC decoders.

mfxU16 **EnableReallocRequest**

For decoders supporting dynamic resolution change (VP9), set this option to ON to allow *MFXVideoDECODE_DecodeFrameAsync* return *MFX_ERR_REALLOC_SURFACE*. See the *CodingOptionValue* enumerator for values of this option. Use the *Query* API function to check if this feature is supported.

mfxU16 **FilmGrain**

Special parameter for AV1 decoder. Indicates presence/absence of film grain parameters in bitstream. Also controls decoding behavior for streams with film grain parameters. *MFXVideoDECODE_DecodeHeader* returns nonzero *FilmGrain* for streams with film grain parameters and zero for streams w/o them. Decoding with film grain requires additional output surfaces. If *FilmGrain`* is non-zero then *MFXVideoDECODE_QueryIOSurf* will request more surfaces in case of external allocated video memory at decoder output. *FilmGrain* is passed to *MFXVideoDECODE_Init* function to control decoding operation for AV1 streams with film grain parameters. If *FilmGrain* is nonzero decoding of each frame require two output surfaces (one for reconstructed frame and one for output frame with film grain applied). The decoder returns *MFX_ERR_MORE_SURFACE* from *MFXVideoDECODE_DecodeFrameAsync* if it has insufficient output surfaces to decode frame. Application can forcibly disable the feature passing zero value of *FilmGrain* to *MFXVideoDECODE_Init*. In this case the decoder will output reconstructed frames w/o film grain applied. Application can retrieve film grain parameters for a frame by attaching extended buffer *mfx-ExtAVIFilmGrainParam* to *mfxFramSurface1*. If stream has no film grain parameters *FilmGrain* passed to *MFXVideoDECODE_Init* is ignored by the decoder.

mfxU16 **IgnoreLevelConstrain**

If not zero, it forces SDK to attempt to decode bitstream even if a decoder may not support all features associated with given *CodecLevel*. Decoder may produce visual artifacts. Only AVC decoder supports this field.

mfxU16 **SkipOutput**

This flag is used to disable output of main decoding channel. When it's ON *SkipOutput = MFX_CODINGOPTION_ON* decoder outputs only video processed channels. For pure decode this flag should be always disabled.

mfxU16 **JPEGChromaFormat**

Specify the chroma sampling format that has been used to encode a JPEG picture. See the *ChromaFormat* enumerator for details.

***mfxU16* Rotation**

Rotation option of the output JPEG picture. See the Rotation enumerator for details.

***mfxU16* JPEGColorFormat**

Specify the color format that has been used to encode a JPEG picture. See the JPEGColorFormat enumerator for details.

***mfxU16* InterleavedDec**

Specify JPEG scan type for decoder. See the JPEGScanType enumerator for details.

***mfxU8* SamplingFactorH[4]**

Horizontal sampling factor.

***mfxU8* SamplingFactorV[4]**

Vertical sampling factor.

***mfxU16* Interleaved**

Specify interleaved or non-interleaved scans. If it is equal to MFX_SCANTYPE_INTERLEAVED then the image is encoded as interleaved, all components are encoded in one scan. See the JPEG Scan Type enumerator for details.

***mfxU16* Quality**

Specifies the image quality if the application does not specified quantization table. The value is from 1 to 100 inclusive. “100” is the best quality.

***mfxU16* RestartInterval**

Specifies the number of MCU in the restart interval. “0” means no restart interval.

Note: The *mfxInfoMFX::InitialDelayInKB*, *mfxInfoMFX::TargetKbps*, *mfxInfoMFX::MaxKbps* parameters are used by the constant bitrate (CBR), variable bitrate control (VBR), and CQP HRD algorithms.

Encoders follow the Hypothetical Reference Decoding (HRD) model. The HRD model assumes that data flows into a buffer of the fixed size BufferSizeInKB with a constant bitrate of TargetKbps. (Estimate the targeted frame size by dividing frame rate by bitrate.)

The decoder starts decoding after the buffer reaches the initial size InitialDelayInKB, which is equivalent to reaching an initial delay of InitialDelayInKB*8000/TargetKbpsms. *In this context, KB is 1000 bytes and Kbps is 1000 bps.*

If InitialDelayInKB or BufferSizeInKB is equal to zero, the value is calculated using bitrate, frame rate, profile, level, and so on.

TargetKbps must be specified for encoding initialization.

For variable bitrate control, the MaxKbps parameter specifies the maximum bitrate at which the encoded data enters the Video Buffering Verifier (VBV) buffer. If MaxKbps is equal to zero, the value is calculated from bitrate, frame rate, profile, and level.

Note: The *mfxInfoMFX::TargetKbps*, *mfxInfoMFX::Accuracy*, *mfxInfoMFX::Convergence* parameters are used by the average variable bitrate control (AVBR) algorithm. The algorithm focuses on overall encoding quality while meeting the specified bitrate, TargetKbps, within the accuracy range, Accuracy, after a Convergence period. This method does not follow HRD and the instant bitrate is not capped or padded.

mfxMVCOperationPoint

struct **mfxMVCOperationPoint**
Describes the MVC operation point.

Public Members

mfxU16 **TemporalId**
Temporal identifier of the operation point.

mfxU16 **LevelIdc**
Level value signaled for the operation point.

mfxU16 **NumViews**
Number of views required for decoding the target output views that correspond to the operation point.

mfxU16 **NumTargetViews**
Number of target output views for the operation point.

mfxU16 ***TargetViewId**
Target output view identifiers for operation point.

mfxMVCViewDependency

struct **mfxMVCViewDependency**
Describes MVC view dependencies.

Public Members

mfxU16 **ViewId**
View identifier of this dependency structure.

mfxU16 **NumAnchorRefsL0**
Number of view components for inter-view prediction in the initial reference picture list RefPicList0 for anchor view components.

mfxU16 **NumAnchorRefsL1**
Number of view components for inter-view prediction in the initial reference picture list RefPicList1 for anchor view components.

mfxU16 **AnchorRefL0[16]**
View identifiers of the view components for inter-view prediction in the initial reference picture list RefPicList0 for anchor view components.

mfxU16 **AnchorRefL1[16]**
View identifiers of the view components for inter-view prediction in the initial reference picture list RefPicList1 for anchor view components.

mfXU16 NumNonAnchorRefsL0

Number of view components for inter-view prediction in the initial reference picture list RefPicList0 for non-anchor view components.

mfXU16 NumNonAnchorRefsL1

Number of view components for inter-view prediction in the initial reference picture list RefPicList1 for non-anchor view components.

mfXU16 NonAnchorRefL0[16]

View identifiers of the view components for inter-view prediction in the initial reference picture list RefPicList0 for non-anchor view components.

mfXPayload**struct mfXPayload**

Describes user data payload in MPEG-2 or SEI message payload in H.264.

For encoding, these payloads can be inserted into the bitstream. The payload buffer must contain a valid formatted payload.

For H.264, this is the sei_message() as specified in the section 7.3.2.3.1 ‘Supplemental enhancement information message syntax’ of the ISO/IEC 14496-10 specification.

For MPEG-2, this is the section 6.2.2.2.2 ‘User data’ of the ISO/IEC 13818-2 specification, excluding the user data start_code.

For decoding, these payloads can be retrieved as the decoder parses the bitstream and caches them in an internal buffer.

Public Members***mfXU32 CtrlFlags***

Additional payload properties. See the PayloadCtrlFlags enumerator for details.

mfXU8 *Data

Pointer to the actual payload data buffer.

mfXU32 NumBit

Number of bits in the payload data

mfXU16 Type

MPEG-2 user data start code or H.264 SEI message type.

mfXU16 BufSize

Payload buffer size in bytes.

Code	Supported Types
MPEG	0x01B2 //User Data
AVC	02 //pan_scan_rect 03 //filler_payload 04 //user_data_registered_itu_t_t35 05 //user_data_unregistered 06 //recovery_point 09 //scene_info 13 //full_frame_freeze 14 //full_frame_freeze_release 15 //full_frame_snapshot 16 //progressive_refinement_segment_start 17 //progressive_refinement_segment_end 19 //film_grain_characteristics 20 //deblocking_filter_display_preference 21 //stereo_video_info 45 //frame_packing_arrangement
HEVC	All

mfxVideoParam

struct **mfxVideoParam**

Configuration parameters for encoding, decoding, transcoding, and video processing.

Public Members

mfxU32 AllocId

Unique component ID that will be passed by the library to *mfxFramAllocRequest*. Useful in pipelines where several components of the same type share the same allocator.

mfxU16 AsyncDepth

Specifies how many asynchronous operations an application performs before the application explicitly synchronizes the result. If zero, the value is not specified.

mfxInfoMFX mfx

Configurations related to encoding, decoding, and transcoding. See the definition of the *mfxInfoMFX* structure for details.

mfxInfoVPP vpp

Configurations related to video processing. See the definition of the *mfxInfoVPP* structure for details.

mfxU16 Protected

Specifies the content protection mechanism. See the Protected enumerator for a list of supported protection schemes.

mfxU16 IOPattern

Input and output memory access types for functions. See the enumerator IOPattern for details. The Query API functions return the natively supported IOPattern if the Query input argument is NULL. This parameter is a mandated input for QueryIOSurf and Init API functions. The output pattern must be specified

for DECODE. The input pattern must be specified for ENCODE. Both input and output pattern must be specified for VPP.

mfxExtBuffer ****ExtParam**

The number of extra configuration structures attached to this structure.

mfxU16 **NumExtParam**

Points to an array of pointers to the extra configuration structures. See the ExtendedBufferID enumerator for a list of extended configurations. The list of extended buffers should not contain duplicated entries, such as entries of the same type. If the *mfxVideoParam* structure is used to query library capability, then the list of extended buffers attached to the input and output *mfxVideoParam* structure should be equal, that is, it should contain the same number of extended buffers of the same type.

mfxVP9SegmentParam

struct **mfxVP9SegmentParam**

Contains features and parameters for the segment.

Public Members

mfxU16 **FeatureEnabled**

Indicates which features are enabled for the segment. See the SegmentFeature enumerator for values for this option. Values from the enumerator can be bit-OR'ed. Support of a particular feature depends on underlying hardware platform. Application can check which features are supported by calling Query.

mfxI16 **QIndexDelta**

Quantization index delta for the segment. Ignored if MFX_VP9_SEGMENT_FEATURE_QINDEX isn't set in FeatureEnabled. Valid range for this parameter is [-255, 255]. If QIndexDelta is out of this range, it will be ignored. If QIndexDelta is within valid range, but sum of base quantization index and QIndexDelta is out of [0, 255], QIndexDelta will be clamped.

mfxI16 **LoopFilterLevelDelta**

Loop filter level delta for the segment. Ignored if MFX_VP9_SEGMENT_FEATURE_LOOP_FILTER is not set in FeatureEnabled. Valid range for this parameter is [-63, 63]. If LoopFilterLevelDelta is out of this range, it will be ignored. If LoopFilterLevelDelta is within valid range, but sum of base loop filter level and LoopFilterLevelDelta is out of [0, 63], LoopFilterLevelDelta will be clamped.

mfxU16 **ReferenceFrame**

Reference frame for the segment. See VP9ReferenceFrame enumerator for values for this option. Ignored if MFX_VP9_SEGMENT_FEATURE_REFERENCE isn't set in FeatureEnabled.

mfExtAV1FilmGrainParam

struct **mfExtAV1FilmGrainParam**

The structure is used by AV-1 decoder to report film grain parameters for decoded frame.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AV1_FILM_GRAIN_PARAM.

mfU16 FilmGrainFlags

Bit map with bit-ORed flags from FilmGrainFlags enum.

mfU16 GrainSeed

Starting value for pseudo-random numbers used during film grain synthesis.

mfU8 RefIdx

Indicate which reference frame contains the film grain parameters to be used for this frame.

mfU8 NumYPoints

The number of points for the piece-wise linear scaling function of the luma component.

mfU8 NumCbPoints

The number of points for the piece-wise linear scaling function of the Cb component.

mfU8 NumCrPoints

The number of points for the piece-wise linear scaling function of the Cr component.

mfAV1FilmGrainPoint PointY[14]

The array of points for luma component.

mfAV1FilmGrainPoint PointCb[10]

The array of points for Cb component.

mfAV1FilmGrainPoint PointCr[10]

The array of points for Cr component.

mfU8 GrainScalingMinus8

The shift - 8 applied to the values of the chroma component. The grain_scaling_minus_8 can take values of 0..3 and determines the range and quantization step of the standard deviation of film grain.

mfU8 ArCoeffLag

The number of auto-regressive coefficients for luma and chroma.

mfU8 ArCoeffsYPlus128[24]

Auto-regressive coefficients used for the Y plane.

mfU8 ArCoeffsCbPlus128[25]

Auto-regressive coefficients used for the Cb plane.

***mfXU8* ArCoeffsCrPlus128[25]**

The number of points for the piece-wise linear scaling function of the Cr component.

***mfXU8* ArCoeffShiftMinus6**

The range of the auto-regressive coefficients. Values of 0, 1, 2, and 3 correspond to the ranges for auto-regressive coefficients of [-2, 2), [-1, 1), [-0.5, 0.5) and [-0.25, 0.25) respectively.

***mfXU8* GrainScaleShift**

Downscaling factor of the grain synthesis process for the Gaussian random numbers .

***mfXU8* CbMult**

The multiplier for the Cb component used in derivation of the input index to the Cb component scaling function.

***mfXU8* CbLumaMult**

The multiplier for the average luma component used in derivation of the input index to the Cb component scaling function.

***mfXU16* CbOffset**

The offset used in derivation of the input index to the Cb component scaling function.

***mfXU8* CrMult**

The multiplier for the Cr component used in derivation of the input index to the Cr component scaling function.

***mfXU8* CrLumaMult**

The multiplier for the average luma component used in derivation of the input index to the Cr component scaling function.

***mfXU16* CrOffset**

The offset used in derivation of the input index to the Cr component scaling function.

mfXAV1FilmGrainPoint

struct **mfXAV1FilmGrainPoint**

Defines film grain point.

Public Members***mfXU8* Value**

The x coordinate for the i-th point of the piece-wise linear scaling function for luma/Cb/Cr component.

***mfXU8* Scaling**

The scaling (output) value for the i-th point of the piecewise linear scaling function for luma/Cb/Cr component.

mfxRect

struct **mfxRect**

The structure describes rectangle coordinates that can be used for ROI or for Cropping.

Public Members

mfxU16 **Left**

X coordinate of region of top-left corner of rectangle.

mfxU16 **Top**

Y coordinate of region of top-left corner of rectangle.

mfxU16 **Right**

X coordinate of region of bottom-right corner of rectangle.

mfxU16 **Bottom**

Y coordinate of region of bottom-right corner of rectangle.

mfxExtHyperModeParam

struct **mfxExtHyperModeParam**

The structure is used for HyperMode initialization.

Public Members

mfxExtBuffer **Header**

Extension buffer header. BufferId must be equal to MFX_EXTBUFF_HYPER_MODE_PARAM.

mfxHyperMode **Mode**

HyperMode implementation behavior.

mfxGUID

struct **mfxGUID**

Represents Globally Unique Identifier (GUID) with memory layout compliant to RFC 4122. See <https://www.rfc-editor.org/info/rfc4122> for details.

Public Members

mfXU8 **Data**[16]
Array to keep GUID.

mfXExtAllocationHints

struct **mfXExtAllocationHints**

The extension buffer specifies surface pool management policy. Absence of the attached buffer means MFX_ALLOCATION_UNLIMITED policy: each call of GetSurfaceForXXX leads to surface allocation.

Public Members

mfXExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ALLOCATION_HINTS.

mfXPoolAllocationPolicy **AllocationPolicy**

Allocation policy.

mfXU32 **NumberToPreAllocate**

How many surfaces to allocate during Init. It's applicable for any policies set by mfXPoolAllocationPolicy::AllocationPolicy even if the requested number exceeds recommended size of the pool.

mfXU32 **DeltaToAllocateOnTheFly**

DeltaToAllocateOnTheFly specifies how many surfaces are allocated in addition to NumberToPreAllocate in MFX_ALLOCATION_LIMITED mode. Maximum number of allocated frames will be NumberToPreAllocate + DeltaToAllocateOnTheFly.

mfXVPPPoolType **VPPPoolType**

Defines what VPP pool is targeted - input or output. Ignored for other components.

mfXU32 **Wait**

Time in milliseconds for GetSurfaceForXXX() and DecodeFrameAsync functions to wait until surface will be available.

mfXU32 **reserved1**[4]

Reserved for future use

mfXRefInterface

struct **mfXRefInterface**

The structure represents reference counted interface structure. The memory is allocated and released by the implementation.

Public Members

mfxHDL Context

The context of the container interface. User should not touch (change, set, null) this pointer.

mfxStructVersion Version

The version of the structure.

mfxStatus (*AddRef)(struct *mfxRefInterface* *ref_interface)

Increments the internal reference counter of the container. The container is not destroyed until the container is released using the *mfxRefInterface::Release* function. *mfxRefInterface::AddRef* should be used each time a new link to the container is created (for example, copy structure) for proper management.

Parameters **ref_interface** – [in] Valid interface.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If interface is NULL.

MFX_ERR_INVALID_HANDLE If *mfxRefInterface->Context* is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (*Release)(struct *mfxRefInterface* *ref_interface)

Decrements the internal reference counter of the container. *mfxRefInterface::Release* should be called after using the *mfxRefInterface::AddRef* function to add a container or when allocation logic requires it.

Parameters **ref_interface** – [in] Valid interface.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If interface is NULL.

MFX_ERR_INVALID_HANDLE If *mfxRefInterface->Context* is invalid (for example NULL).

MFX_ERR_UNDEFINED_BEHAVIOR If Reference Counter of container is zero before call.

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (*GetRefCounter)(struct *mfxRefInterface* *ref_interface, *mfxU32* *counter)

Returns current reference counter of *mfxRefInterface* structure.

Parameters

- **ref_interface** – [in] Valid interface.
- **counter** – [out] Sets counter to the current reference counter value.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If interface or counter is NULL.

MFX_ERR_INVALID_HANDLE If *mfxRefInterface->Context* is invalid (for example NULL).

MFx_ERR_UNKNOWN Any internal error.

mfExtMasteringDisplayColourVolume

struct **mfExtMasteringDisplayColourVolume**

Handle the HDR SEI message.

During encoding: If the application attaches this structure to the *mfEncodeCtrl* structure at runtime, the encoder inserts the HDR SEI message for the current frame and ignores *InsertPayloadToggle*. If the application attaches this structure to the *mfVideoParam* structure during initialization or reset, the encoder inserts the HDR SEI message based on *InsertPayloadToggle*.

During video processing: If the application attaches this structure for video processing, *InsertPayloadToggle* will be ignored. And *DisplayPrimariesX[3]*, *DisplayPrimariesY[3]* specify the color primaries where 0,1,2 specifies Red, Green, Blue respectively.

During decoding: If the application attaches this structure to the *mfFrameSurface1* structure at runtime which will send to the *MFVideoDECODE_DecodeFrameAsync()* as *surface_work* parameter, the decoder will parse the HDR SEI message if the bitstream include HDR SEI message per frame. The parsed HDR SEI will be attached to the *ExtendBuffer* of *surface_out* parameter of *MFVideoDECODE_DecodeFrameAsync()* with flag *InsertPayloadToggle* to indicate if there is valid HDR SEI message in the clip. *InsertPayloadToggle* will be set to *MF_PAYLOAD_IDR* if *OneVPL* get valid HDR SEI, otherwise it will be set to *MF_PAYLOAD_OFF*. This function is support for HEVC only now.

Field semantics are defined in ITU-T* H.265 Annex D.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to *MF_EXTBUFF_MASTERING_DISPLAY_COLOUR_VOLUME*

mfU16 **InsertPayloadToggle**

InsertHDRPayload enumerator value.

mfU16 **DisplayPrimariesX[3]**

Color primaries for a video source in increments of 0.00002. Consist of RGB x coordinates and define how to convert colors from RGB color space to CIE XYZ color space. Fields range is 0 to 50000.

mfU16 **DisplayPrimariesY[3]**

Color primaries for a video source in increments of 0.00002. Consists of RGB y coordinates and defines how to convert colors from RGB color space to CIE XYZ color space. Field range is 0 to 50000.

mfU16 **WhitePointX**

White point X coordinate.

mfU16 **WhitePointY**

White point Y coordinate.

mfU32 **MaxDisplayMasteringLuminance**

Specify maximum luminance of the display on which the content was authored in units of 0.00001 candelas per square meter. Field range is 1 to 65535.

***mf*xU32 MinDisplayMasteringLuminance**

Specify minimum luminance of the display on which the content was authored in units of 0.00001 candelas per square meter. Field range is 1 to 65535.

mfExtContentLightLevelInfo

struct **mfExtContentLightLevelInfo**

Handle the HDR SEI message.

During encoding: If the application attaches this structure to the *mfEncodeCtrl* structure at runtime, the encoder inserts the HDR SEI message for the current frame and ignores InsertPayloadToggle. If the application attaches this structure to the *mfVideoParam* structure during initialization or reset, the encoder inserts the HDR SEI message based on InsertPayloadToggle.

During video processing: If the application attaches this structure for video processing, InsertPayloadToggle will be ignored.

During decoding: If the application attaches this structure to the *mfFrameSurface1* structure at runtime which will seed to the MFXVideoDECODE_DecodeFrameAsync() as surface_work parameter, the decoder will parse the HDR SEI message if the bitstream include HDR SEI message per frame. The parsed HDR SEI will be attached to the ExtendBuffer of surface_out parameter of MFXVideoDECODE_DecodeFrameAsync() with flag InsertPayloadToggle to indicate if there is valid HDR SEI message in the clip. InsertPayloadToggle will be set to MFX_PAYLOAD_IDR if OneVPL get valid HDR SEI, otherwise it will be set to MFX_PAYLOAD_OFF. This function is support for HEVC only now.

Field semantics are defined in ITU-T* H.265 Annex D.

Public Members***mfExtBuffer* Header**

Extension buffer header. Header.BufferId must be equal to EXTBUFF_CONTENT_LIGHT_LEVEL_INFO.

***mf*xU16 InsertPayloadToggle**

InsertHDRPayload enumerator value.

***mf*xU16 MaxContentLightLevel**

Maximum luminance level of the content. Field range is 1 to 65535.

***mf*xU16 MaxPicAverageLightLevel**

Maximum average per-frame luminance level of the content. Field range is 1 to 65535.

Decode Structures

Structures used by Decode only.

API

- *mfxDcodeStat*
- *mfxEtDcodeErrorReport*
- *mfxEtDcodedFrameInfo*
- *mfxEtTimeCode*

mfxDcodeStat

struct **mfxDcodeStat**

Returns statistics collected during decoding.

Public Members

mfxU32 **NumFrame**

Number of total decoded frames.

mfxU32 **NumSkippedFrame**

Number of skipped frames.

mfxU32 **NumError**

Number of errors recovered.

mfxU32 **NumCachedFrame**

Number of internally cached frames.

mfxEtDcodeErrorReport

struct **mfxEtDcodeErrorReport**

Used by the decoders to report bitstream error information right after DecodeHeader or DecodeFrameAsync. The application can attach this extended buffer to the *mfxBitstream* structure at runtime.

Public Members

mfxEtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_DECODE_ERROR_REPORT.

mfxU32 **ErrorTypes**

Bitstream error types (bit-ORed values). See ErrorTypes enumerator for the list of types.

mfExtDecodedFrameInfo

struct **mfExtDecodedFrameInfo**

Used by the decoders to report additional information about a decoded frame. The application can attach this extended buffer to the `mfFrameSurface1::mfFrameData` structure at runtime.

Public Members

mfExtBuffer **Header**

Extension buffer header. `Header.BufferId` must be equal to `MFX_EXTBUFF_DECODED_FRAME_INFO`.

mfU16 **FrameType**

Frame type. See `FrameType` enumerator for the list of types.

mfExtTimeCode

struct **mfExtTimeCode**

Used by the library to pass MPEG 2 specific timing information.

See ISO/IEC 13818-2 and ITU-T H.262, MPEG-2 Part 2 for the definition of these parameters.

Public Members

mfExtBuffer **Header**

Extension buffer header. `Header.BufferId` must be equal to `MFX_EXTBUFF_TIME_CODE`.

mfU16 **DropFrameFlag**

Indicated dropped frame.

mfU16 **TimeCodeHours**

Hours.

mfU16 **TimeCodeMinutes**

Minutes.

mfU16 **TimeCodeSeconds**

Seconds.

mfU16 **TimeCodePictures**

Pictures.

Encode Structures

Structures used by Encode only.

mfxBRCFrameCtrl

struct **mfxBRCFrameCtrl**

Specifies controls for next frame encoding provided by external BRC functions.

Public Members

mfXI32 **QpY**

Frame-level Luma QP.

mfXI32 **InitialCpbRemovalDelay**

See `initial_cpb_removal_delay` in codec standard. Ignored if no HRD control: *mfXExtCodingOption::VuiNalHrdParameters* = MFX_CODINGOPTION_OFF. Calculated by encoder if `initial_cpb_removal_delay==0` && `initial_cpb_removal_offset == 0` && HRD control is switched on.

mfXI32 **InitialCpbRemovalOffset**

See `initial_cpb_removal_offset` in codec standard. Ignored if no HRD control: *mfXExtCodingOption::VuiNalHrdParameters* = MFX_CODINGOPTION_OFF. Calculated by encoder if `initial_cpb_removal_delay==0` && `initial_cpb_removal_offset == 0` && HRD control is switched on.

mfXI32 **MaxFrameSize**

Max frame size in bytes. Option for repack feature. Driver calls PAK until current frame size is less than or equal to `MaxFrameSize`, or number of repacking for this frame is equal to `MaxNumRePak`. Repack is available if there is driver support, `MaxFrameSize != 0`, and `MaxNumRePak != 0`. Ignored if `MaxNumRePak == 0`.

mfXI8 **DeltaQP[8]**

Option for repack feature. Ignored if `MaxNumRePak == 0` or `MaxNumRePak==0`. If current frame size > `MaxFrameSize` and/or number of repacking (`nRepack`) for this frame <= `MaxNumRePak`, PAK is called with `QP = mfxBRCFrameCtrl::QpY + Sum(DeltaQP[i])`, where `i = [0,nRepack]`. Non zero `DeltaQP[nRepack]` are ignored if `nRepack > MaxNumRePak`. If repacking feature is on (`MaxFrameSize` & `MaxNumRePak` are not zero), it is calculated by the encoder.

mfXI16 **MaxNumRepak**

Number of possible repacks in driver if current frame size > `MaxFrameSize`. Ignored if `MaxFrameSize==0`. See `MaxFrameSize` description. Possible values are in the range of 0 to 8.

mfXI16 **NumExtParam**

Reserved for future use.

mfXExtBuffer ****ExtParam**

Reserved for future use.

mfxBRCFrameParam

struct **mfxBRCFrameParam**

Describes frame parameters required for external BRC functions.

Public Members

mfxU16 **SceneChange**

Frame belongs to a new scene if non zero.

mfxU16 **LongTerm**

Frame is a Long Term Reference frame if non zero.

mfxU32 **FrameCmplx**

Frame Complexity Frame spatial complexity if non zero. Zero if complexity is not available.

mfxU32 **EncodedOrder**

The frame number in a sequence of reordered frames starting from encoder Init.

mfxU32 **DisplayOrder**

The frame number in a sequence of frames in display order starting from last IDR.

mfxU32 **CodedFrameSize**

Size of the frame in bytes after encoding.

mfxU16 **FrameType**

Frame type. See FrameType enumerator for possible values.

mfxU16 **PyramidLayer**

B-pyramid or P-pyramid layer that the frame belongs to.

mfxU16 **NumRecode**

Number of recodings performed for this frame.

mfxU16 **NumExtParam**

Reserved for future use.

mfxExtBuffer ****ExtParam**

Reserved for future use.

Frame spatial complexity is calculated according to the following formula:

$$R = \frac{16}{WH} \sum_{k=0}^{\frac{W}{4}-1} \sum_{l=0}^{\frac{H}{4}-1} \left[\frac{\sum_{i=0}^3 \sum_{j=0}^3 |P[k * 4 + i][l * 4 + j] - P[k * 4 + i - 1][l * 4 + j]|}{16} \right]$$

$$C = \frac{16}{WH} \sum_{k=0}^{\frac{W}{4}-1} \sum_{l=0}^{\frac{H}{4}-1} \left[\frac{\sum_{i=0}^3 \sum_{j=0}^3 |P[k * 4 + i][l * 4 + j] - P[k * 4 + i][l * 4 + j - 1]|}{16} \right]$$

$$FrameCmplx = \sqrt{R^2 + C^2}$$

mfxBRCFrameStatus

struct **mfxBRCFrameStatus**

Specifies instructions for the encoder provided by external BRC after each frame encoding. See the BRCStatus enumerator for details.

Public Members

mfxU32 **MinFrameSize**

Size in bytes, coded frame must be padded to when Status = MFX_BRC_PANIC_SMALL_FRAME.

mfxU16 **BRCStatus**

BRC status. See the BRCStatus enumerator for possible values.

mfxEncodeCtrl

struct **mfxEncodeCtrl**

Contains parameters for per-frame based encoding control.

Public Members

mfxExtBuffer **Header**

This extension buffer doesn't have assigned buffer ID. Ignored.

mfxU16 **MfxNalUnitType**

Type of NAL unit that contains encoding frame. All supported values are defined by MfxNalUnitType enumerator. Other values defined in ITU-T H.265 specification are not supported.

The encoder uses this field only if application sets *mfxExtCodingOption3::EnableNalUnitType* option to ON during encoder initialization.

Note: Only encoded order is supported. If application specifies this value in display order or uses value inappropriate for current frame or invalid value, then the encoder silently ignores it.

mfxU16 SkipFrame

Indicates that current frame should be skipped or the number of missed frames before the current frame. See *mfxExtCodingOption2::SkipFrame* for details.

mfxU16 QP

If nonzero, this value overwrites the global QP value for the current frame in the constant QP mode.

mfxU16 FrameType

Encoding frame type. See the FrameType enumerator for details. If the encoder works in the encoded order, the application must specify the frame type. If the encoder works in the display order, only key frames are enforceable.

mfxU16 NumExtParam

Number of extra control buffers.

mfxU16 NumPayload

Number of payload records to insert into the bitstream.

mfxExtBuffer **ExtParam

Pointer to an array of pointers to external buffers that provide additional information or control to the encoder for this frame or field pair. A typical use is to pass the VPP auxiliary data generated by the video processing pipeline to the encoder. See the ExtendedBufferID for the list of extended buffers.

mfxPayload **Payload

Pointer to an array of pointers to user data (MPEG-2) or SEI messages (H.264) for insertion into the bitstream. For field pictures, odd payloads are associated with the first field and even payloads are associated with the second field. See the *mfxPayload* structure for payload definitions.

mfxEncodedUnitInfo

struct **mfxEncodedUnitInfo**

Used to report encoded unit information.

Public Members***mfxU16 Type***

Codec-dependent coding unit type (NALU type for AVC/HEVC, start_code for MPEG2 etc).

mfxU32 Offset

Offset relative to the associated *mfxBitstream::DataOffset*.

mfxU32 Size

Unit size, including delimiter.

mfxEncodeStat

struct **mfxEncodeStat**

Returns statistics collected during encoding.

Public Members

mfxU32 **NumFrame**

Number of encoded frames.

mfxU64 **NumBit**

Number of bits for all encoded frames.

mfxU32 **NumCachedFrame**

Number of internally cached frames.

mfxExtAVCEncodedFrameInfo

struct **mfxExtAVCEncodedFrameInfo**

Used by the encoder to report additional information about the encoded picture. The application can attach this buffer to the *mfxBitstream* structure before calling MFXVideoENCODE_EncodeFrameAsync function. For interlaced content the encoder requires two such structures. They correspond to fields in encoded order.

Note: Not all implementations of the encoder support this extended buffer. The application must use query mode 1 to determine if the functionality is supported. To do this, the application must attach this extended buffer to the *mfxVideoParam* structure and call the MFXVideoENCODE_Query function. If the function returns MFX_ERR_NONE then the functionality is supported.

Reference Lists

The following structure members are used by the reference lists contained in the parent structure.

mfxU32 **FrameOrder**

Frame order of encoded picture.

Frame order of reference picture.

mfxU16 **PicStruct**

Picture structure of encoded picture.

Picture structure of reference picture.

mfxU16 **LongTermIdx**

Long term index of encoded picture if applicable.

Long term index of reference picture if applicable.

mfxU16 **reserved[2]**

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ENCODED_FRAME_INFO.

mfxU32 MAD

Mean Absolute Difference between original pixels of the frame and motion compensated (for inter macroblocks) or spatially predicted (for intra macroblocks) pixels. Only luma component, Y plane, is used in calculation.

mfxU16 BRCPanicMode

Bitrate control was not able to allocate enough bits for this frame. Frame quality may be unacceptably low.

mfxU16 QP

Luma QP.

mfxU32 SecondFieldOffset

Offset to second field. Second field starts at *mfxBitstream::Data* + *mfxBitstream::DataOffset* + *mfxExtAVCEncodedFrameInfo::SecondFieldOffset*.

struct *mfxExtAVCEncodedFrameInfo*::[anonymous] **UsedRefListL0**[32]

Reference list that has been used to encode picture.

struct *mfxExtAVCEncodedFrameInfo*::[anonymous] **UsedRefListL1**[32]

Reference list that has been used to encode picture.

mfxExtAVCRefListCtrl

struct ***mfxExtAVCRefListCtrl***

Configures reference frame options for the H.264 encoder. See the *Reference List Selection* and *Long Term Reference Frame* sections for more details.

Note: Not all implementations of the encoder support LongTermIdx and ApplyLongTermIdx fields in this structure. The application must use query mode 1 to determine if such functionality is supported. To do this, the application must attach this extended buffer to the *mfxVideoParam* structure and call the MFXVideoENCODE_Query function. If the function returns MFX_ERR_NONE and these fields were set to one, then the functionality is supported. If the function fails or sets fields to zero, then the functionality is not supported.

Reference Lists

The following structure members are used by the reference lists contained in the parent structure.

mfxU32 FrameOrder

Together FrameOrder and PicStruct fields are used to identify reference picture. Use FrameOrder = MFX_FRAMEORDER_UNKNOWN to mark unused entry.

***mfxU16* PicStruct**

Together FrameOrder and PicStruct fields are used to identify reference picture. Use FrameOrder = MFX_FRAMEORDER_UNKNOWN to mark unused entry.

***mfxU16* ViewId**

Reserved and must be zero.

***mfxU16* LongTermIdx**

Index that should be used by the encoder to mark long-term reference frame.

***mfxU16* reserved[3]**

Reserved

Public Members***mfxExtBuffer* Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AVC_REFLIST_CTRL.

***mfxU16* NumRefIdxL0Active**

Specify the number of reference frames in the active reference list L0. This number should be less or equal to the NumRefFrame parameter from encoding initialization.

***mfxU16* NumRefIdxL1Active**

Specify the number of reference frames in the active reference list L1. This number should be less or equal to the NumRefFrame parameter from encoding initialization.

struct *mfxExtAVCRefListCtrl*::[anonymous] **PreferredRefList**[32]

Reference list that specifies the list of frames that should be used to predict the current frame.

struct *mfxExtAVCRefListCtrl*::[anonymous] **RejectedRefList**[16]

Reference list that specifies the list of frames that should not be used for prediction.

struct *mfxExtAVCRefListCtrl*::[anonymous] **LongTermRefList**[16]

Reference list that specifies the list of frames that should be marked as long-term reference frame.

***mfxU16* ApplyLongTermIdx**

If it is equal to zero, the encoder assigns long-term index according to internal algorithm. If it is equal to one, the encoder uses LongTermIdx value as long-term index.

mfxExtAVCRefLists

struct **mfxExtAVCRefLists**

Specifies reference lists for the encoder. It may be used together with the *mfxExtAVCRefListCtrl* structure to create customized reference lists. If both structures are used together, then the encoder takes reference lists from the *mfxExtAVCRefLists* structure and modifies them according to the *mfxExtAVCRefListCtrl* instructions. In case of interlaced coding, the first *mfxExtAVCRefLists* structure affects TOP field and the second - BOTTOM field.

Note: Not all implementations of the encoder support this structure. The application must use the Query API function to determine if it is supported.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AVC_REFLISTS.

mfxU16 NumRefIdxL0Active

Specify the number of reference frames in the active reference list L0. This number should be less than or equal to the NumRefFrame parameter from encoding initialization.

mfxU16 NumRefIdxL1Active

Specify the number of reference frames in the active reference list L1. This number should be less than or equal to the NumRefFrame parameter from encoding initialization.

struct *mfxExtAVCRefLists::mfxRefPic* RefPicList0[32]

Specify L0 reference list.

struct *mfxExtAVCRefLists::mfxRefPic* RefPicList1[32]

Specify L1 reference list.

struct **mfxRefPic**

Used by the reference lists contained in the parent structure. Together these fields are used to identify reference picture.

Public Members

mfxU32 FrameOrder

Use FrameOrder = MFX_FRAMEORDER_UNKNOWN to mark unused entry.

mfxU16 PicStruct

Use PicStruct = MFX_PICSTRUCT_FIELD_TFF for TOP field, PicStruct = MFX_PICSTRUCT_FIELD_BFF for BOTTOM field.

mfxExtAVCRoundingOffset

struct **mfxExtAVCRoundingOffset**

Used by encoders to set rounding offset parameters for quantization. It is per-frame based encoding control, and can be attached to some frames and skipped for others. When the extension buffer is set the application can attach it to the *mfxEncodeCtrl* during runtime.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AVC_ROUNDING_OFFSET.

mfU16 EnableRoundingIntra

Enable rounding offset for intra blocks. See the CodingOptionValue enumerator for values of this option.

mfU16 RoundingOffsetIntra

Intra rounding offset. Value must be in the range of 0 to 7, inclusive.

mfU16 EnableRoundingInter

Enable rounding offset for inter blocks. See the CodingOptionValue enumerator for values of this option.

mfU16 RoundingOffsetInter

Inter rounding offset. Value must be in the range of 0 to 7, inclusive.

mfExtAvcTemporalLayers

struct **mfExtAvcTemporalLayers**

Configures the H.264 temporal layers hierarchy.

If the application attaches it to the *mfVideoParam* structure during initialization, the encoder generates the temporal layers and inserts the prefix NAL unit before each slice to indicate the temporal and priority IDs of the layer.

This structure can be used with the display-order encoding mode only.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AVC_TEMPORAL_LAYERS.

mfU16 BaseLayerPID

The priority ID of the base layer. The encoder increases the ID for each temporal layer and writes to the prefix NAL unit.

mfU16 Scale

The ratio between the frame rates of the current temporal layer and the base layer.

mfExtBRC

struct **mfExtBRC**

Contains a set of callbacks to perform external bitrate control. Can be attached to the *mfVideoParam* structure during encoder initialization. Set the *mfExtCodingOption2::ExtBRC* option to ON to make the encoder use the external BRC instead of the native one.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_BRC.

mfHDL pthis

Pointer to the BRC object.

mfStatus (*Init)(*mfHDL* pthis, *mfVideoParam* *par)

Initializes the BRC session according to parameters from input *mfVideoParam* and attached structures. It does not modify the input *mfVideoParam* and attached structures. Invoked during MFXVideoENCODE_Init.

Parameters

- **pthis** – [in] Pointer to the BRC object.
- **par** – [in] Pointer to the *mfVideoParam* structure that was used for the encoder initialization.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_UNSUPPORTED The function detected unsupported video parameters.

mfStatus (*Reset)(*mfHDL* pthis, *mfVideoParam* *par)

Resets BRC session according to new parameters. It does not modify the input *mfVideoParam* and attached structures. Invoked during MFXVideoENCODE_Reset.

Parameters

- **pthis** – [in] Pointer to the BRC object.
- **par** – [in] Pointer to the *mfVideoParam* structure that was used for the encoder initialization.

Returns

MFX_ERR_NONE The function completed successfully.

MFX_ERR_UNSUPPORTED The function detected unsupported video parameters.

MFX_ERR_INCOMPATIBLE_VIDEO_PARAM The function detected that the video parameters provided by the application are incompatible with initialization parameters. Reset requires additional memory allocation and cannot be executed.

mfStatus (*Close)(*mfHDL* pthis)

Deallocates any internal resources acquired in Init for this BRC session. Invoked during MFXVideoENCODE_Close.

Parameters **pthis** – [in] Pointer to the BRC object.

Returns MFX_ERR_NONE The function completed successfully.

mfxStatus (***GetFrameCtrl**)(*mfxHDL* pthis, *mfxBRCFrameParam* *par, *mfxBRCFrameCtrl* *ctrl)

Returns controls (ctrl) to encode next frame based on info from input *mfxBRCFrameParam* structure (par) and internal BRC state. Invoked asynchronously before each frame encoding or recoding.

Parameters

- **pthis** – [in] Pointer to the BRC object.
- **par** – [in] Pointer to the *mfxVideoParam* structure that was used for the encoder initialization.
- **ctrl** – [out] Pointer to the output *mfxBRCFrameCtrl* structure.

Returns MFX_ERR_NONE The function completed successfully.

mfxStatus (***Update**)(*mfxHDL* pthis, *mfxBRCFrameParam* *par, *mfxBRCFrameCtrl* *ctrl, *mfxBRCFrameStatus* *status)

Updates internal BRC state and returns status to instruct encoder whether it should recode the previous frame, skip the previous frame, do padding, or proceed to next frame based on info from input *mfxBRCFrameParam* and *mfxBRCFrameCtrl* structures. Invoked asynchronously after each frame encoding or recoding.

Parameters

- **pthis** – [in] Pointer to the BRC object.
- **par** – [in] Pointer to the *mfxVideoParam* structure that was used for the encoder initialization.
- **ctrl** – [in] Pointer to the output *mfxBRCFrameCtrl* structure.
- **status** – [in] Pointer to the output *mfxBRCFrameStatus* structure.

Returns MFX_ERR_NONE The function completed successfully.

mfxExtChromaLocInfo

struct **mfxExtChromaLocInfo**

Members of this structure define the location of chroma samples information.

See Annex E of the ISO*VIEC* 14496-10 specification for the definition of these parameters.

Public Members

mfxExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_CHROMA_LOC_INFO.

mfxU16 **ChromaLocInfoPresentFlag**

mfxU16 **ChromaSampleLocTypeTopField**

mfxU16 **ChromaSampleLocTypeBottomField**

mfxU16 **reserved[9]**

mfxExtCodingOption

struct **mfxExtCodingOption**

Specifies additional options for encoding.

The application can attach this extended buffer to the *mfxVideoParam* structure to configure initialization.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_CODING_OPTION.

mfxU16 RateDistortionOpt

Set this flag if rate distortion optimization is needed. See the CodingOptionValue enumerator for values of this option.

mfxU16 MECostType

Motion estimation cost type. This value is reserved and must be zero.

mfxU16 MESearchType

Motion estimation search algorithm. This value is reserved and must be zero.

mfxI16Pair MVSearchWindow

Rectangular size of the search window for motion estimation. This parameter is reserved and must be (0, 0).

mfxU16 FramePicture

Set this flag to encode interlaced fields as interlaced frames. This flag does not affect progressive input frames. See the CodingOptionValue enumerator for values of this option.

mfxU16 CAVLC

If set, CAVLC is used; if unset, CABAC is used for encoding. See the CodingOptionValue enumerator for values of this option.

mfxU16 RecoveryPointSEI

Set this flag to insert the recovery point SEI message at the beginning of every intra refresh cycle. See the description of IntRefType in *mfxExtCodingOption2* structure for details on how to enable and configure intra refresh.

If intra refresh is not enabled then this flag is ignored.

See the CodingOptionValue enumerator for values of this option.

mfxU16 ViewOutput

Set this flag to instruct the MVC encoder to output each view in separate bitstream buffer. See the CodingOptionValue enumerator for values of this option and the Multi-View Video Coding section for more details about usage of this flag.

mfxU16 NalHrdConformance

If this option is turned ON, then AVC encoder produces an HRD conformant bitstream. If it is turned OFF, then the AVC encoder may (but not necessarily) violate HRD conformance. That is, this option can force the encoder to produce an HRD conformant stream, but cannot force it to produce a non-conformant stream.

See the CodingOptionValue enumerator for values of this option.

mfXU16 **SingleSeiNalUnit**

If set, encoder puts all SEI messages in the single NAL unit. It includes messages provided by application and created by encoder. It is a three-states option. See CodingOptionValue enumerator for values of this option. The three states are:

- UNKNOWN Put each SEI in its own NAL unit.
- ON Put all SEI messages in the same NAL unit.
- OFF The same as unknown.

mfXU16 **VuiVclHrdParameters**

If set and VBR rate control method is used, then VCL HRD parameters are written in bitstream with values identical to the values of the NAL HRD parameters. See the CodingOptionValue enumerator for values of this option.

mfXU16 **RefPicListReordering**

Set this flag to activate reference picture list reordering. This value is reserved and must be zero.

mfXU16 **ResetRefList**

Set this flag to reset the reference list to non-IDR I-frames of a GOP sequence. See the CodingOptionValue enumerator for values of this option.

mfXU16 **RefPicMarkRep**

Set this flag to write the reference picture marking repetition SEI message into the output bitstream. See the CodingOptionValue enumerator for values of this option.

mfXU16 **FieldOutput**

Set this flag to instruct the AVC encoder to output bitstreams immediately after the encoder encodes a field, in the field-encoding mode. See the CodingOptionValue enumerator for values of this option.

mfXU16 **IntraPredBlockSize**

Minimum block size of intra-prediction. This value is reserved and must be zero.

mfXU16 **InterPredBlockSize**

Minimum block size of inter-prediction. This value is reserved and must be zero.

mfXU16 **MVPrecision**

Specify the motion estimation precision. This parameter is reserved and must be zero.

mfXU16 **MaxDecFrameBuffering**

Specifies the maximum number of frames buffered in a DPB. A value of zero means unspecified.

mfXU16 **AUDelimiter**

Set this flag to insert the Access Unit Delimiter NAL. See the CodingOptionValue enumerator for values of this option.

mfXU16 **PicTimingSEI**

Set this flag to insert the picture timing SEI with pic_struct syntax element. See sub-clauses D.1.2 and D.2.2

of the ISO/IEC 14496-10 specification for the definition of this syntax element. See the `CodingOptionValue` enumerator for values of this option. The default value is ON.

mfxU16 **VuiNalHrdParameters**

Set this flag to insert NAL HRD parameters in the VUI header. See the `CodingOptionValue` enumerator for values of this option.

mfxExtCodingOption2

struct **mfxExtCodingOption2**

Used with the *mfxExtCodingOption* structure to specify additional options for encoding.

The application can attach this extended buffer to the *mfxVideoParam* structure to configure initialization and to the *mfxEncodeCtrl* during runtime.

Public Members

mfxExtBuffer **Header**

Extension buffer header. `Header.BufferId` must be equal to `MFX_EXTBUFF_CODING_OPTION2`.

mfxU16 **IntRefType**

Specifies intra refresh type. See the `IntraRefreshTypes`. The major goal of intra refresh is improvement of error resilience without significant impact on encoded bitstream size caused by I-frames. The encoder achieves this by encoding part of each frame in the refresh cycle using intra MBs.

This parameter is valid during initialization and runtime. When used with temporal scalability, intra refresh applied only to base layer.

`MFX_REFRESH_NO` No refresh.

`MFX_REFRESH_VERTICAL` Vertical refresh, by column of MBs.

`MFX_REFRESH_HORIZONTAL` Horizontal refresh, by rows of MBs.

`MFX_REFRESH_SLICE` Horizontal refresh by slices without overlapping.

`MFX_REFRESH_SLICE` Library ignores `IntRefCycleSize` (size of refresh cycle equals number slices).

mfxU16 **IntRefCycleSize**

Specifies number of pictures within refresh cycle starting from 2. 0 and 1 are invalid values. This parameter is valid only during initialization.

mfxI16 **IntRefQPDelta**

Specifies QP difference for inserted intra MBs. Signed values are in the -51 to 51 range. This parameter is valid during initialization and runtime.

mfxU32 **MaxFrameSize**

Specify maximum encoded frame size in byte. This parameter is used in VBR based bitrate control modes and ignored in others. The encoder tries to keep frame size below specified limit but minor overshoots are possible to preserve visual quality. This parameter is valid during initialization and runtime. It is recommended to set `MaxFrameSize` to $5x-10x$ target frame size $((\text{TargetKbps} * 1000) / (8 * \text{FrameRateExtN} / \text{FrameRateExtD}))$ for I-frames and $2x-4x$ target frame size for P- and B-frames.

***mfxU32* MaxSliceSize**

Specify maximum slice size in bytes. If this parameter is specified other controls over number of slices are ignored.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

***mfxU16* BitrateLimit**

Modifies bitrate to be in the range imposed by the encoder. The default value is ON, that is, bitrate is limited. Setting this flag to OFF may lead to violation of HRD conformance. Specifying bitrate below the encoder range might significantly affect quality.

If set to ON, this option takes effect in non CQP modes: if TargetKbps is not in the range imposed by the encoder, it will be changed to be in the range.

This parameter is valid only during initialization. Flag works with MFX_CODEC_AVC only, it is ignored with other codecs. See the CodingOptionValue enumerator for values of this option.

***mfxU16* MBBRC**

Setting this flag enables macroblock level bitrate control that generally improves subjective visual quality. Enabling this flag may have negative impact on performance and objective visual quality metric. See the CodingOptionValue enumerator for values of this option. The default value depends on target usage settings.

***mfxU16* ExtBRC**

Set this option to ON to enable external BRC. See the CodingOptionValue enumerator for values of this option. Use the Query API function to check if this feature is supported.

***mfxU16* LookAheadDepth**

Specifies the depth of the look ahead rate control algorithm. The depth value is the number of frames that the encoder analyzes before encoding. Values are in the 10 to 100 range, inclusive. To instruct the encoder to use the default value the application should zero this field.

***mfxU16* Trellis**

Used to control trellis quantization in AVC encoder. See TrellisControl enumerator for values of this option. This parameter is valid only during initialization.

***mfxU16* RepeatPPS**

Controls picture parameter set repetition in AVC encoder. Set this flag to ON to repeat PPS with each frame. See the CodingOptionValue enumerator for values of this option. The default value is ON. This parameter is valid only during initialization.

***mfxU16* BRefType**

Controls usage of B-frames as reference. See BRefControl enumerator for values of this option. This parameter is valid only during initialization.

***mfxU16* AdaptiveI**

Controls insertion of I-frames by the encoder. Set this flag to ON to allow changing of frame type from P and B to I. This option is ignored if GopOptFlag in *mfxInfoMFX* structure is equal to MFX_GOP_STRICT. See the CodingOptionValue enumerator for values of this option. This parameter is valid only during initialization.

mfxU16 AdaptiveB

Controls changing of frame type from B to P. Set this flag to ON enable changing of frame type from B to P. This option is ignored if `GopOptFlag` in *mfxInfoMFX* structure is equal to `MFX_GOP_STRICT`. See the `CodingOptionValue` enumerator for values of this option. This parameter is valid only during initialization.

mfxU16 LookAheadDS

Controls down sampling in look ahead bitrate control mode. See `LookAheadDownSampling` enumerator for values of this option. This parameter is valid only during initialization.

mfxU16 NumMbPerSlice

Specifies suggested slice size in number of macroblocks. The library can adjust this number based on platform capability. If this option is specified, that is, if it is not equal to zero, the library ignores *mfxInfoMFX::NumSlice* parameter.

mfxU16 SkipFrame

Enables usage of *mfxEncodeCtrl::SkipFrame* parameter. See the `SkipFrame` enumerator for values of this option.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU8 MinQPI

Minimum allowed QP value for I-frame types. Valid range is 1 to 51 inclusive. Zero means default value, that is, no limitations on QP.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU8 MaxQPI

Maximum allowed QP value for I-frame types. Valid range is 1 to 51 inclusive. Zero means default value, that is, no limitations on QP.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU8 MinQPP

Minimum allowed QP value for P-frame types. Valid range is 1 to 51 inclusive. Zero means default value, that is, no limitations on QP.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU8 MaxQPP

Maximum allowed QP value for P-frame types. Valid range is 1 to 51 inclusive. Zero means default value, that is, no limitations on QP.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU8 **MinQPB**

Minimum allowed QP value for B-frame types. Valid range is 1 to 51 inclusive. Zero means default value, that is, no limitations on QP.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU8 **MaxQPB**

Maximum allowed QP value for B-frame types. Valid range is 1 to 51 inclusive. Zero means default value, that is, no limitations on QP.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU16 **FixedFrameRate**

Sets `fixed_frame_rate_flag` in VUI.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU16 **DisableDeblockingIdc**

Disables deblocking.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU16 **DisableVUI**

Completely disables VUI in the output bitstream.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfxU16 **BufferingPeriodSEI**

Controls insertion of buffering period SEI in the encoded bitstream. It should be one of the following values:

MFx_BPSEI_DEFAULT Encoder decides when to insert BP SEI,

MFx_BPSEI_IFRAME BP SEI should be inserted with every I-frame.

mfxU16 **EnableMAD**

Set this flag to ON to enable per-frame reporting of Mean Absolute Difference. This parameter is valid only during initialization.

mfXU16 **UseRawRef**

Set this flag to ON to use raw frames for reference instead of reconstructed frames. This parameter is valid during initialization and runtime (only if was turned ON during initialization).

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

mfXExtCodingOption3

struct **mfXExtCodingOption3**

Used with *mfXExtCodingOption* and *mfXExtCodingOption2* structures to specify additional options for encoding. The application can attach this extended buffer to the *mfXVideoParam* structure to configure initialization and to the *mfXEncodeCtrl* during runtime.

Public Members

mfXExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_CODING_OPTION3.

mfXU16 **NumSliceI**

The number of slices for I-frames.

Note: Not all codecs and implementations support these values. Use the Query API function to check if this feature is supported

mfXU16 **NumSliceP**

The number of slices for P-frames.

Note: Not all codecs and implementations support these values. Use the Query API function to check if this feature is supported

mfXU16 **NumSliceB**

The number of slices for B-frames.

Note: Not all codecs and implementations support these values. Use the Query API function to check if this feature is supported

mfXU16 **WinBRMaxAvgKbps**

When rate control method is MFX_RATECONTROL_VBR, MFX_RATECONTROL_LA,

MFX_RATECONTROL_LA_HRD, or MFX_RATECONTROL_QVBR this parameter specifies the maximum bitrate averaged over a sliding window specified by WinBRCSize. For MFX_RATECONTROL_CBR this parameter is ignored and equals TargetKbps.

mfxU16 **WinBRCSize**

When rate control method is MFX_RATECONTROL_CBR, MFX_RATECONTROL_VBR, MFX_RATECONTROL_LA, MFX_RATECONTROL_LA_HRD, or MFX_RATECONTROL_QVBR this parameter specifies sliding window size in frames. Set this parameter to zero to disable sliding window.

mfxU16 **QVBRQuality**

When rate control method is MFX_RATECONTROL_QVBR, this parameter specifies quality factor. Values are in the 1 to 51 range, where 1 corresponds to the best quality.

mfxU16 **EnableMBQP**

Set this flag to ON to enable per-macroblock QP control. Rate control method must be MFX_RATECONTROL_CQP. See the CodingOptionValue enumerator for values of this option. This parameter is valid only during initialization.

mfxU16 **IntRefCycleDist**

Distance between the beginnings of the intra-refresh cycles in frames. Zero means no distance between cycles.

mfxU16 **DirectBiasAdjustment**

Set this flag to ON to enable the ENC mode decision algorithm to bias to fewer B Direct/Skip types. Applies only to B-frames, all other frames will ignore this setting. See the CodingOptionValue enumerator for values of this option.

mfxU16 **GlobalMotionBiasAdjustment**

Enables global motion bias. See the CodingOptionValue enumerator for values of this option.

mfxU16 **MVCostScalingFactor**

Values are:

- 0: Set MV cost to be 0.
- 1: Scale MV cost to be 1/2 of the default value.
- 2: Scale MV cost to be 1/4 of the default value.
- 3: Scale MV cost to be 1/8 of the default value.

mfxU16 **MBDisableSkipMap**

Set this flag to ON to enable usage of *mfxExtMBDisableSkipMap*. See the CodingOptionValue enumerator for values of this option. This parameter is valid only during initialization.

mfxU16 **WeightedPred**

Weighted prediction mode. See the WeightedPred enumerator for values of these options.

mfxU16 **WeightedBiPred**

Weighted prediction mode. See the WeightedPred enumerator for values of these options.

mfXU16 AspectRatioInfoPresent

Instructs encoder whether aspect ratio info should present in VUI parameters. See the CodingOptionValue enumerator for values of this option.

mfXU16 OverscanInfoPresent

Instructs encoder whether overscan info should present in VUI parameters. See the CodingOptionValue enumerator for values of this option.

mfXU16 OverscanAppropriate

ON indicates that the cropped decoded pictures output are suitable for display using overscan. OFF indicates that the cropped decoded pictures output contain visually important information in the entire region out to the edges of the cropping rectangle of the picture. See the CodingOptionValue enumerator for values of this option.

mfXU16 TimingInfoPresent

Instructs encoder whether frame rate info should present in VUI parameters. See the CodingOptionValue enumerator for values of this option.

mfXU16 BitstreamRestriction

Instructs encoder whether bitstream restriction info should present in VUI parameters. See the CodingOptionValue enumerator for values of this option.

mfXU16 LowDelayHrd

Corresponds to AVC syntax element `low_delay_hrd_flag` (VUI). See the CodingOptionValue enumerator for values of this option.

mfXU16 MotionVectorsOverPicBoundaries

When set to OFF, no sample outside the picture boundaries and no sample at a fractional sample position for which the sample value is derived using one or more samples outside the picture boundaries is used for inter prediction of any sample.

When set to ON, one or more samples outside picture boundaries may be used in inter prediction.

See the CodingOptionValue enumerator for values of this option.

mfXU16 ScenarioInfo

Provides a hint to encoder about the scenario for the encoding session. See the ScenarioInfo enumerator for values of this option.

mfXU16 ContentInfo

Provides a hint to encoder about the content for the encoding session. See the ContentInfo enumerator for values of this option.

mfXU16 PRefType

When `GopRefDist=1`, specifies the model of reference list construction and DPB management. See the PRefType enumerator for values of this option.

mfXU16 FadeDetection

Instructs encoder whether internal fade detection algorithm should be used for calculation of weigh/offset values for `pred_weight_table` unless application provided *mfXExtPredWeightTable* for this frame. See the CodingOptionValue enumerator for values of this option.

mfXU16 GPB

Set this flag to OFF to make HEVC encoder use regular P-frames instead of GPB. See the CodingOption-Value enumerator for values of this option.

mfXU32 MaxFrameSizeI

Same as *mfXExtCodingOption2::MaxFrameSize* but affects only I-frames. MaxFrameSizeI must be set if MaxFrameSizeP is set. If MaxFrameSizeI is not specified or greater than spec limitation, spec limitation will be applied to the sizes of I-frames.

mfXU32 MaxFrameSizeP

Same as *mfXExtCodingOption2::MaxFrameSize* but affects only P/B-frames. If MaxFrameSizeP equals 0, the library sets MaxFrameSizeP equal to MaxFrameSizeI. If MaxFrameSizeP is not specified or greater than spec limitation, spec limitation will be applied to the sizes of P/B-frames.

mfXU16 EnableQPOffset

Enables QPOffset control. See the CodingOptionValue enumerator for values of this option.

mfXI16 QPOffset[8]

Specifies QP offset per pyramid layer when EnableQPOffset is set to ON and RateControlMethod is CQP.

For B-pyramid, B-frame $QP = QPB + QPOffset[layer]$.

For P-pyramid, P-frame $QP = QPP + QPOffset[layer]$.

mfXU16 NumRefActiveP[8]

Max number of active references for P-frames. Array index is pyramid layer.

mfXU16 NumRefActiveBL0[8]

Max number of active references for B-frames in reference picture list 0. Array index is pyramid layer.

mfXU16 NumRefActiveBL1[8]

Max number of active references for B-frames in reference picture list 1. Array index is pyramid layer.

mfXU16 TransformSkip

For HEVC if this option is turned ON, the transform_skip_enabled_flag will be set to 1 in PPS. OFF specifies that transform_skip_enabled_flag will be set to 0.

mfXU16 TargetChromaFormatPlus1

Minus 1 specifies target encoding chroma format (see ChromaFormatIdc enumerator). May differ from the source format. TargetChromaFormatPlus1 = 0 specifies the default target chroma format which is equal to source (*mfXVideoParam::mfX::FrameInfo::ChromaFormat* + 1), except RGB4 source format. In case of RGB4 source format default target , chroma format is 4:2:0 (instead of 4:4:4) for the purpose of backward compatibility.

mfXU16 TargetBitDepthLuma

Target encoding bit-depth for luma samples. May differ from source bit-depth. 0 specifies a default target bit-depth that is equal to source (*mfXVideoParam::mfX::FrameInfo::BitDepthLuma*).

mfXU16 TargetBitDepthChroma

Target encoding bit-depth for chroma samples. May differ from source bit-depth. 0 specifies a default target bit-depth that is equal to source (*mfXVideoParam::mfX::FrameInfo::BitDepthChroma*).

***mfxU16* BRCPanicMode**

Controls panic mode in AVC and MPEG2 encoders.

***mfxU16* LowDelayBRC**

When rate control method is MFX_RATECONTROL_VBR, MFX_RATECONTROL_QVBR or MFX_RATECONTROL_VCM this parameter specifies frame size tolerance. Set this parameter to MFX_CODINGOPTION_ON to allow strictly obey average frame size set by MaxKbps, for example cases when $\text{MaxFrameSize} == (\text{MaxKbps} * 1000) / (8 * \text{FrameRateExtN} / \text{FrameRateExtD})$. Also MaxFrameSizeI and MaxFrameSizeP can be set separately.

***mfxU16* EnableMBForceIntra**

Set this flag to ON to enable usage of *mfxExtMBForceIntra* for AVC encoder. See the CodingOptionValue enumerator for values of this option. This parameter is valid only during initialization.

***mfxU16* AdaptiveMaxFrameSize**

If this flag is set to ON, BRC may decide a larger P- or B-frame size than what MaxFrameSizeP dictates when the scene change is detected. It may benefit the video quality. AdaptiveMaxFrameSize feature is not supported with LowPower ON or if the value of MaxFrameSizeP = 0.

***mfxU16* RepartitionCheckEnable**

Controls AVC encoder attempts to predict from small partitions. Default value allows encoder to choose preferred mode. MFX_CODINGOPTION_ON forces encoder to favor quality and MFX_CODINGOPTION_OFF forces encoder to favor performance.

***mfxU16* EncodedUnitsInfo**

Set this flag to ON to make encoded units info available in *mfxExtEncodedUnitsInfo*.

***mfxU16* EnableNalUnitType**

If this flag is set to ON, the HEVC encoder uses the NAL unit type provided by the application in the *mfxEncodeCtrl::MfxNalUnitType* field. This parameter is valid only during initialization.

Note: Not all codecs and implementations support this value. Use the Query API function to check if this feature is supported.

***mfxU16* AdaptiveLTR**

If this flag is set to ON, encoder will mark, modify, or remove LTR frames based on encoding parameters and content

properties. Turn OFF to prevent Adaptive marking of Long Term Reference Frames.

***mfxU16* AdaptiveCQM**

If this flag is set to ON, encoder adaptively selects one of implementation-defined quantization matrices for each frame. Non-default quantization matrices aim to improve subjective visual quality under certain conditions. Their number and definitions are API implementation specific. If this flag is set to OFF, default quantization matrix is used for all frames. This parameter is valid only during initialization.

***mfxU16* AdaptiveRef**

If this flag is set to ON, encoder adaptively selects list of reference frames to improve encoding quality. Enabling of the flag can increase computation complexity and introduce additional delay. If this flag is set to OFF, regular reference frames are used for encoding.

***mfxU16* CPUEncToolsProcessing**

The tri-state option specifies hint for the library to execute encoding tools processing on CPU. It may give better encoding quality, but leads to higher CPU utilization. The library can ignore MFX_CODINGOPTION_ON if processing on CPU is not supported.

mfxExtCodingOptionSPSPPS**struct *mfxExtCodingOptionSPSPPS***

Attach this structure as part of the extended buffers to configure the encoder during MFXVideoENCODE_Init. The sequence or picture parameters specified by this structure overwrite any parameters specified by the structure or any other attached extended buffers attached.

For H.264, SPSBuffer and PPSBuffer must point to valid bitstreams that contain the sequence parameter set and picture parameter set, respectively.

For MPEG-2, SPSBuffer must point to valid bitstreams that contain the sequence header followed by any sequence header extension. The PPSBuffer pointer is ignored.

The encoder imports parameters from these buffers. If the encoder does not support the specified parameters, the encoder does not initialize and returns the status code MFX_ERR_INCOMPATIBLE_VIDEO_PARAM.

Check with the MFXVideoENCODE_Query function for the support of this multiple segment encoding feature. If this feature is not supported, the query returns MFX_ERR_UNSUPPORTED.

Public Members***mfxExtBuffer* Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_CODING_OPTION_SPSPPS.

***mfxU8* *SPSBuffer**

Pointer to a valid bitstream that contains the SPS (sequence parameter set for H.264 or sequence header followed by any sequence header extension for MPEG-2) buffer. Can be NULL to skip specifying the SPS.

***mfxU8* *PPSBuffer**

Pointer to a valid bitstream that contains the PPS (picture parameter set for H.264 or picture header followed by any picture header extension for MPEG-2) buffer. Can be NULL to skip specifying the PPS.

***mfxU16* SPSBufSize**

Size of the SPS in bytes.

***mfxU16* PPSBufSize**

Size of the PPS in bytes.

***mfxU16* SPSId**

SPS identifier. The value is reserved and must be zero.

***mfxU16* PPSId**

PPS identifier. The value is reserved and must be zero.

mfExtCodingOptionVPS

struct **mfExtCodingOptionVPS**

Attach this structure as part of the extended buffers to configure the encoder during MFXVideoENCODE_Init. The sequence or picture parameters specified by this structure overwrite any parameters specified by the structure or any other attached extended buffers attached.

If the encoder does not support the specified parameters, the encoder does not initialize and returns the status code MFX_ERR_INCOMPATIBLE_VIDEO_PARAM.

Check with the MFXVideoENCODE_Query function for the support of this multiple segment encoding feature. If this feature is not supported, the query returns MFX_ERR_UNSUPPORTED.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_CODING_OPTION_VPS.

mfU8 ***VPSBuffer**

Pointer to a valid bitstream that contains the VPS (video parameter set for HEVC) buffer.

mfU16 **VPSBufSize**

Size of the VPS in bytes.

mfU16 **VPSId**

VPS identifier; the value is reserved and must be zero.

mfExtDirtyRect

struct **mfExtDirtyRect**

Used by the application to specify dirty regions within a frame during encoding. It may be used at initialization or at runtime.

Dirty rectangle definition is using end-point exclusive notation. In other words, the pixel with (Right, Bottom) coordinates lies immediately outside of the dirty rectangle. Left, Top, Right, Bottom should be aligned by codec-specific block boundaries (should be dividable by 16 for AVC, or by block size (8, 16, 32 or 64, depends on platform) for HEVC).

Every dirty rectangle with unaligned coordinates will be expanded to a minimal-area block-aligned dirty rectangle, enclosing the original one. For example, a (5, 5, 15, 31) dirty rectangle will be expanded to (0, 0, 16, 32) for AVC encoder, or to (0, 0, 32, 32) for HEVC, if block size is 32.

Dirty rectangle (0, 0, 0, 0) is a valid dirty rectangle and means that the frame is not changed.

Dirty rectangle coordinates

The following structure members are used by the Rect array contained in the parent structure.

mfXU32 **Left**

Dirty region left coordinate.

mfXU32 **Top**

Dirty region top coordinate.

mfXU32 **Right**

Dirty region right coordinate.

mfXU32 **Bottom**

Dirty region bottom coordinate.

Public Members

mfXExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_DIRTY_RECTANGLES.

mfXU16 **NumRect**

Number of dirty rectangles.

struct *mfXExtDirtyRect*::[anonymous] **Rect**[256]

Array of dirty rectangles.

mfXExtEncodedUnitsInfo

struct **mfXExtEncodedUnitsInfo**

If *mfXExtCodingOption3::EncodedUnitsInfo* was set to MFX_CODINGOPTION_ON during encoder initialization, the *mfXExtEncodedUnitsInfo* structure is attached to the *mfXBitstream* structure during encoding. It is used to report information about coding units in the resulting bitstream.

The number of filled items in UnitInfo is min(NumUnitsEncoded, NumUnitsAlloc).

For counting a minimal amount of encoded units you can use the following algorithm:

```
nSEI = amountOfApplicationDefinedSEI;
if (CodingOption3.NumSlice[IPB] != 0 || mfxVideoParam.mfx.NumSlice != 0)
    ExpectedAmount = 10 + nSEI + Max(CodingOption3.NumSlice[IPB], mfxVideoParam.mfx.
↳ NumSlice);
else if (CodingOption2.NumMBPerSlice != 0)
    ExpectedAmount = 10 + nSEI + (FrameWidth * FrameHeight) / (256 * CodingOption2.
↳ NumMBPerSlice);
else if (CodingOption2.MaxSliceSize != 0)
    ExpectedAmount = 10 + nSEI + Round(MaxBitrate / (FrameRate * CodingOption2.
↳ MaxSliceSize));
else
    ExpectedAmount = 10 + nSEI;
```

(continues on next page)

(continued from previous page)

```

if (mfxFrameInfo.PictStruct != MFX_PICSTRUCT_PROGRESSIVE)
    ExpectedAmount = ExpectedAmount * 2;

if (temporalScaleabilityEnabled)
    ExpectedAmount = ExpectedAmount * 2;

```

Note: Only supported by the AVC encoder.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ENCODED_UNITS_INFO.

mfxEncodedUnitInfo *UnitInfo

Pointer to an array of mfxEncodedUnitsInfo structures whose size is equal to or greater than NumUnitsAlloc.

mfxU16 NumUnitsAlloc

UnitInfo array size.

mfxU16 NumUnitsEncoded

Output field. Number of coding units to report. If NumUnitsEncoded is greater than NumUnitsAlloc, the UnitInfo array will contain information only for the first NumUnitsAlloc units. User may consider reallocating the UnitInfo array to avoid this for subsequent frames.

mfxExtEncoderCapability

struct **mfxExtEncoderCapability**

Used to retrieve encoder capability. See the description of mode 4 of the MFXVideoENCODE_Query function for details on how to use this structure.

Note: Not all implementations of the encoder support this extended buffer. The application must use query mode 1 to determine if the functionality is supported. To do this, the application must attach this extended buffer to the *mfxVideoParam* structure and call the MFXVideoENCODE_Query function. If the function returns MFX_ERR_NONE then the functionality is supported.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ENCODER_CAPABILITY.

mfxU32 MBPerSec

Specify the maximum processing rate in macro blocks per second.

mfxExtEncoderIPCMArea

struct **mfxExtEncoderIPCMArea**

Specifies rectangle areas for IPCM coding mode.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ENCODER_IPCM_AREA.

struct *mfxExtEncoderIPCMArea::area* *Areas

Array of areas.

struct **area**

Number of areas

Public Members

mfxU32 Left

Left area coordinate.

mfxU32 Top

Top area coordinate.

mfxU32 Right

Right area coordinate.

mfxU32 Bottom

Bottom area coordinate.

mfExtEncoderResetOption

struct **mfExtEncoderResetOption**

Used to control the encoder behavior during reset. By using this structure, the application instructs the encoder to start a new coded sequence after reset or to continue encoding of the current sequence.

This structure is also used in mode 3 of the MFXVideoENCODE_Query function to check for reset outcome before actual reset. The application should set StartNewSequence to the required behavior and call the query function. If the query fails (see status codes below), then reset is not possible in current encoder state. If the application sets StartNewSequence to MFX_CODINGOPTION_UNKNOWN, then the query function replaces the coding option with the actual reset type: MFX_CODINGOPTION_ON if the encoder will begin a new sequence after reset or MFX_CODINGOPTION_OFF if the encoder will continue the current sequence.

Using this structure may cause one of the following status codes from the MFXVideoENCODE_Reset and MFXVideoENCODE_Query functions:

- MFX_ERR_INVALID_VIDEO_PARAM If a reset is not possible. For example, the application sets StartNewSequence to off and requests resolution change.
- MFX_ERR_INCOMPATIBLE_VIDEO_PARAM If the application requests change that leads to memory allocation. For example, the application sets StartNewSequence to on and requests resolution change to greater than the initialization value.
- MFX_ERR_NONE If reset is possible.

The following limited list of parameters can be changed without starting a new coded sequence:

- The bitrate parameters, TargetKbps and MaxKbps, in the *mfInfoMFX* structure.
- The number of slices, NumSlice, in the *mfInfoMFX* structure. Number of slices should be equal to or less than the number of slices during initialization.
- The number of temporal layers in the *mfExtAvcTemporalLayers* structure. Reset should be called immediately before encoding of frame from base layer and number of reference frames should be large enough for the new temporal layers structure.
- The quantization parameters, QPI, QPP and QPB, in the *mfInfoMFX* structure.

The application should retrieve all cached frames before calling reset. When the Query API function checks for reset outcome, it expects that this requirement be satisfied. If it is not true and there are some cached frames inside the encoder, then the query result may differ from the reset result, because the encoder may insert an IDR frame to produce valid coded sequence. See the *Configuration Change* section for more information.

See the *Streaming and Video Conferencing Features* section for more information.

Note: Not all implementations of the encoder support this extended buffer. The application must use query mode 1 to determine if the functionality is supported. To do this, the application must attach this extended buffer to the *mfVideoParam* structure and call the MFXVideoENCODE_Query function. If the function returns MFX_ERR_NONE, then the functionality is supported.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ENCODER_RESET_OPTION.

mfU16 StartNewSequence

Instructs encoder to start new sequence after reset. Use one of the CodingOptionValue options:

- MFX_CODINGOPTION_ON The encoder completely reset internal state and begins new coded sequence after reset, including insertion of IDR frame, sequence, and picture headers.
- MFX_CODINGOPTION_OFF The encoder continues encoding of current coded sequence after reset, without insertion of IDR frame.
- MFX_CODINGOPTION_UNKNOWN Depending on the current encoder state and changes in configuration parameters, the encoder may or may not start new coded sequence. This value is also used to query reset outcome.

mfExtEncoderROI

struct **mfExtEncoderROI**

Used by the application to specify different Region Of Interests during encoding. It may be used at initialization or at runtime.

ROI location rectangle

The ROI rectangle definition uses end-point exclusive notation. In other words, the pixel with (Right, Bottom) coordinates lies immediately outside of the ROI. Left, Top, Right, Bottom should be aligned by codec-specific block boundaries (should be dividable by 16 for AVC, or by 32 for HEVC). Every ROI with unaligned coordinates will be expanded by the library to minimal-area block-aligned ROI, enclosing the original one. For example (5, 5, 15, 31) ROI will be expanded to (0, 0, 16, 32) for AVC encoder, or to (0, 0, 32, 32) for HEVC.

mfU32 Left

Left ROI's coordinate.

mfU32 Top

Top ROI's coordinate.

mfU32 Right

Right ROI's coordinate.

mfU32 Bottom

Bottom ROI's coordinate.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ENCODER_ROI.

mfxU16 NumROI

Number of ROI descriptions in array. The Query API function mode 2 returns maximum supported value (set it to 256 and query will update it to maximum supported value).

mfxU16 ROIMode

QP adjustment mode for ROIs. Defines if Priority or DeltaQP is used during encoding.

mfxI16 Priority

Priority of ROI. Used if ROIMode = MFX_ROI_MODE_PRIORITY. This is an absolute value in the range of -3 to 3, which will be added to the MB QP. Priority is deprecated mode and is used only for backward compatibility. Bigger value produces better quality.

mfxI16 DeltaQP

Delta QP of ROI. Used if ROIMode = MFX_ROI_MODE_QP_DELTA. This is an absolute value in the range of -51 to 51, which will be added to the MB QP. Lesser value produces better quality.

struct *mfxExtEncoderROI*::[anonymous] ROI[256]

Array of ROIs. Different ROI may overlap each other. If macroblock belongs to several ROI, Priority from ROI with lowest index is used.

mfxExtHEVCRegion

struct **mfxExtHEVCRegion**

Attached to the *mfxVideoParam* structure during HEVC encoder initialization. Specifies the region to encode.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_HEVC_REGION.

mfxU32 RegionId

ID of region.

mfxU16 RegionType

Type of region. See HEVCRegionType enumerator for the list of types.

mfxU16 RegionEncoding

Set to MFX_HEVC_REGION_ENCODING_ON to encode only specified region.

mfExtHEVCTiles

struct **mfExtHEVCTiles**

Configures tiles options for the HEVC encoder. The application can attach this extended buffer to the *mfVideoParam* structure to configure initialization.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_HEVC_TILES.

mfU16 **NumTileRows**

Number of tile rows.

mfU16 **NumTileColumns**

Number of tile columns.

mfExtInsertHeaders

struct **mfExtInsertHeaders**

Runtime ctrl buffer for SPS/PPS insertion with current encoding frame.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_INSERT_HEADERS.

mfU16 **SPS**

Tri-state option to insert SPS.

mfU16 **PPS**

Tri-state option to insert PPS.

mfU16 **reserved**[8]

mfExtMBDisableSkipMap

struct **mfExtMBDisableSkipMap**

Specifies macroblock map for current frame which forces specified macroblocks to be non-skip if *mfExtCodingOption3::MBDisableSkipMap* was turned ON during encoder initialization. The application can attach this extended buffer to the *mfEncodeCtrl* structure during runtime.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_MB_DISABLE_SKIP_MAP.

mfxU32 MapSize

Macroblock map size.

mfxU8 *Map

Pointer to a list of non-skip macroblock flags in raster scan order. Each flag is one byte in map. Set flag to 1 to force corresponding macroblock to be non-skip. In case of interlaced encoding, the first half of map affects the top field and the second half of map affects the bottom field.

mfxExtMBForceIntra

struct **mfxExtMBForceIntra**

Specifies macroblock map for current frame which forces specified macroblocks to be encoded as intra if *mfx-ExtCodingOption3::EnableMBForceIntra* was turned ON during encoder initialization. The application can attach this extended buffer to the *mfxEncodeCtrl* structure during runtime.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_MB_FORCE_INTRA.

mfxU32 MapSize

Macroblock map size.

mfxU8 *Map

Pointer to a list of force intra macroblock flags in raster scan order. Each flag is one byte in map. Set flag to 1 to force corresponding macroblock to be encoded as intra. In case of interlaced encoding, the first half of map affects top field and the second half of map affects the bottom field.

mfxExtMBQP

struct **mfxExtMBQP**

Specifies per-macroblock QP for current frame if *mfxExtCodingOption3::EnableMBQP* was turned ON during encoder initialization. The application can attach this extended buffer to the *mfxEncodeCtrl* structure during runtime.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_MBQP.

mfxU32 Pitch

Distance in bytes between the start of two consecutive rows in the QP array.

mfxU16 Mode

Defines QP update mode. See MBQPMode enumerator for more details.

mfxU16 BlockSize

QP block size, valid for HEVC only during Init and Runtime.

mfxU32 NumQPAlloc

Size of allocated by application QP or DeltaQP array.

mfxU8 *QP

Pointer to a list of per-macroblock QP in raster scan order. In case of interlaced encoding the first half of QP array affects the top field and the second half of QP array affects the bottom field. Valid when Mode = MFX_MBQP_MODE_QP_VALUE.

For AVC, the valid range is 1 to 51.

For HEVC, the valid range is 1 to 51. Application's provided QP values should be valid. Otherwise invalid QP values may cause undefined behavior. MBQP map should be aligned for 16x16 block size. The alignment rule is $(width + 15 / 16) \&\& (height + 15 / 16)$.

For MPEG2, QP corresponds to quantizer_scale of the ISO*VIEC* 13818-2 specification and has a valid range of 1 to 112.

mfxI8 *DeltaQP

Pointer to a list of per-macroblock QP deltas in raster scan order. For block i: $QP[i] = BrcQP[i] + DeltaQP[i]$. Valid when Mode = MFX_MBQP_MODE_QP_DELTA.

mfxQPandMode *QPmode

Block-granularity modes when MFX_MBQP_MODE_QP_ADAPTIVE is set.

mfxExtMoveRect

struct **mfxExtMoveRect**

Used by the application to specify moving regions within a frame during encoding.

Destination rectangle location should be aligned to MB boundaries (should be dividable by 16). If not, the encoder truncates it to MB boundaries, for example, both 17 and 31 will be truncated to 16.

Destination and source rectangle location

The following structure members are used by the Rect array contained in the parent structure.

mfXU32 **DestLeft**
Destination rectangle location.

mfXU32 **DestTop**
Destination rectangle location.

mfXU32 **DestRight**
Destination rectangle location.

mfXU32 **DestBottom**
Destination rectangle location.

mfXU32 **SourceLeft**
Source rectangle location.

mfXU32 **SourceTop**
Source rectangle location.

Public Members

mfXExtBuffer **Header**
Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_MOVING_RECTANGLE.

mfXU16 **NumRect**
Number of moving rectangles.

struct *mfXExtMoveRect*::[anonymous] **Rect**[256]
Array of moving rectangles.

mfXExtMVOverPicBoundaries

struct **mfXExtMVOverPicBoundaries**
Instructs encoder to use or not use samples over specified picture border for inter prediction. Attached to the *mfXVideoParam* structure.

Public Members

mfXExtBuffer **Header**
Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_MV_OVER_PIC_BOUNDARIES.

mfXU16 **StickTop**
When set to OFF, one or more samples outside corresponding picture boundary may be used in inter prediction. See the CodingOptionValue enumerator for values of this option.

***mfxU16* StickBottom**

When set to OFF, one or more samples outside corresponding picture boundary may be used in inter prediction. See the CodingOptionValue enumerator for values of this option.

***mfxU16* StickLeft**

When set to OFF, one or more samples outside corresponding picture boundary may be used in inter prediction. See the CodingOptionValue enumerator for values of this option.

***mfxU16* StickRight**

When set to OFF, one or more samples outside corresponding picture boundary may be used in inter prediction. See the CodingOptionValue enumerator for values of this option.

mfxExtPartialBitstreamParam**struct mfxExtPartialBitstreamParam**

Used by an encoder to output parts of the bitstream as soon as they are ready. The application can attach this extended buffer to the *mfxVideoParam* structure at initialization. If this option is turned ON (Granularity != MFX_PARTIAL_BITSTREAM_NONE), then the encoder can output bitstream by part based on the required granularity.

This parameter is valid only during initialization and reset. Absence of this buffer means default or previously configured bitstream output behavior.

Note: Not all codecs and implementations support this feature. Use the Query API function to check if this feature is supported.

Public Members***mfxExtBuffer* Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_PARTIAL_BITSTREAM_PARAM.

***mfxU32* BlockSize**

Output block granularity for PartialBitstreamGranularity. Valid only for MFX_PARTIAL_BITSTREAM_BLOCK.

***mfxU16* Granularity**

Granularity of the partial bitstream: slice/block/any, all types of granularity state in PartialBitstreamOutput enum.

mfExtPictureTimingSEI

struct **mfExtPictureTimingSEI**

Configures the H.264 picture timing SEI message. The encoder ignores it if HRD information in the stream is absent and the PicTimingSEI option in the *mfExtCodingOption* structure is turned off. See *mfExtCodingOption* for details.

If the application attaches this structure to the *mfVideoParam* structure during initialization, the encoder inserts the picture timing SEI message based on provided template in every access unit of coded bitstream.

If application attaches this structure to the *mfEncodeCtrl* structure at runtime, the encoder inserts the picture timing SEI message based on provided template in access unit that represents current frame.

These parameters define the picture timing information. An invalid value of 0xFFFF indicates that application does not set the value and encoder must calculate it.

See Annex D of the ISO*VIEC* 14496-10 specification for the definition of these parameters.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_PICTURE_TIMING_SEI.

mfU32 **reserved**[14]

mfU16 **ClockTimestampFlag**

mfU16 **CtType**

mfU16 **NuitFieldBasedFlag**

mfU16 **CountingType**

mfU16 **FullTimestampFlag**

mfU16 **DiscontinuityFlag**

mfU16 **CntDroppedFlag**

mfU16 **NFrames**

mfU16 **SecondsFlag**

mfU16 **MinutesFlag**

mfU16 **HoursFlag**

mfU16 **SecondsValue**

mfU16 **MinutesValue**

mfU16 **HoursValue**

mfU32 **TimeOffset**

struct *mfExtPictureTimingSEI*::[anonymous] **TimeStamp**[3]

mfExtPredWeightTable

struct **mfExtPredWeightTable**

Specifies weighted prediction table for current frame when all of the following conditions are met:

- *mfExtCodingOption3::WeightedPred* was set to explicit during encoder Init or Reset .
- The current frame is P-frame or *mfExtCodingOption3::WeightedBiPred* was set to explicit during encoder Init or Reset.
- The current frame is B-frame and is attached to the *mfEncodeCtrl* structure.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_PRED_WEIGHT_TABLE.

mfU16 LumaLog2WeightDenom

Base 2 logarithm of the denominator for all luma weighting factors. Value must be in the range of 0 to 7, inclusive.

mfU16 ChromaLog2WeightDenom

Base 2 logarithm of the denominator for all chroma weighting factors. Value must be in the range of 0 to 7, inclusive.

mfU16 LumaWeightFlag[2][32]

LumaWeightFlag[L][R] equal to 1 specifies that the weighting factors for the luma component are specified for R's entry of RefPicList L.

mfU16 ChromaWeightFlag[2][32]

ChromaWeightFlag[L][R] equal to 1 specifies that the weighting factors for the chroma component are specified for R's entry of RefPicList L.

mfI16 Weights[2][32][3][2]

The values of the weights and offsets used in the encoding processing. The value of Weights[i][j][k][m] is interpreted as: i refers to reference picture list 0 or 1; j refers to reference list entry 0-31; k refers to data for the luma component when it is 0, the Cb chroma component when it is 1 and the Cr chroma component when it is 2; m refers to weight when it is 0 and offset when it is 1

mfExtVP8CodingOption

struct **mfExtVP8CodingOption**

Describes VP8 coding options.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VP8_CODING_OPTION.

mfU16 Version

Determines the bitstream version. Corresponds to the same VP8 syntax element in frame_tag.

mfU16 EnableMultipleSegments

Set this option to ON to enable segmentation. This is tri-state option. See the CodingOptionValue enumerator for values of this option.

mfU16 LoopFilterType

Select the type of filter (normal or simple). Corresponds to VP8 syntax element filter_type.

mfU16 LoopFilterLevel[4]

Controls the filter strength. Corresponds to VP8 syntax element loop_filter_level.

mfU16 SharpnessLevel

Controls the filter sensitivity. Corresponds to VP8 syntax element sharpness_level.

mfU16 NumTokenPartitions

Specifies number of token partitions in the coded frame.

mfI16 LoopFilterRefTypeDelta[4]

Loop filter level delta for reference type (intra, last, golden, altref).

mfI16 LoopFilterMbModeDelta[4]

Loop filter level delta for MB modes.

mfI16 SegmentQPDelta[4]

QP delta for segment.

mfI16 CoeffTypeQPDelta[5]

QP delta for coefficient type (YDC, Y2AC, Y2DC, UVAC, UVDC).

mfU16 WriteIVFHeaders

Set this option to ON to enable insertion of IVF container headers into bitstream. This is tri-state option. See the CodingOptionValue enumerator for values of this option

mfU32 NumFramesForIVFHeader

Specifies number of frames for IVF header when WriteIVFHeaders is ON.

mfExtVP9Segmentation

struct **mfExtVP9Segmentation**

In the VP9 encoder it is possible to divide a frame into up to 8 segments and apply particular features (like delta for quantization index or for loop filter level) on a per-segment basis. “Uncompressed header” of every frame indicates if segmentation is enabled for the current frame, and (if segmentation enabled) contains full information about features applied to every segment. Every “Mode info block” of a coded frame has `segment_id` in the range of 0 to 7.

To enable Segmentation, the *mfExtVP9Segmentation* structure with correct settings should be passed to the encoder. It can be attached to the *mfxVideoParam* structure during initialization or the `MFXVideoENCODE_Reset` call (static configuration). If the *mfExtVP9Segmentation* buffer isn't attached during initialization, segmentation is disabled for static configuration. If the buffer isn't attached for the Reset call, the encoder continues to use static configuration for segmentation which was the default before this Reset call. If the *mfExtVP9Segmentation* buffer with `NumSegments=0` is provided during initialization or Reset call, segmentation becomes disabled for static configuration.

The buffer can be attached to the *mfxEncodeCtrl* structure during runtime (dynamic configuration). Dynamic configuration is applied to the current frame only. After encoding of the current frame, the encoder will switch to the next dynamic configuration or to static configuration if dynamic configuration is not provided for next frame).

The `SegmentIdBlockSize`, `NumSegmentIdAlloc`, and `SegmentId` parameters represent a segmentation map. Here, the segmentation map is an array of `segment_ids` (one byte per `segment_id`) for blocks of size `NxN` in raster scan order. The size `NxN` is specified by the application and is constant for the whole frame. If *mfExtVP9Segmentation* is attached during initialization and/or during runtime, all three parameters should be set to proper values that do not conflict with each other and with `NumSegments`. If any of the parameters are not set or any conflict or error in these parameters is detected by the library, the segmentation map will be discarded.

Public Members

mfExtBuffer Header

Extension buffer header. `Header.BufferId` must be equal to `MFX_EXTBUFF_VP9_SEGMENTATION`.

mfU16 NumSegments

Number of segments for frame. Value 0 means that segmentation is disabled. Sending 0 for a particular frame will disable segmentation for this frame only. Sending 0 to the Reset API function will disable segmentation permanently. Segmentation can be enabled again by a subsequent Reset call.

mfVP9SegmentParam Segment[8]

Array of *mfVP9SegmentParam* structures containing features and parameters for every segment. Entries with indexes bigger than `NumSegments-1` are ignored. See the *mfVP9SegmentParam* structure for definitions of segment features and their parameters.

mfU16 SegmentIdBlockSize

Size of block (`NxN`) for segmentation map. See `SegmentIdBlockSize` enumerator for values for this option. An encoded block that is bigger than `SegmentIdBlockSize` uses `segment_id` taken from it's top-left sub-block from the segmentation map. The application can check if a particular block size is supported by calling `Query`.

mfU32 NumSegmentIdAlloc

Size of buffer allocated for segmentation map (in bytes). Application must assure that `NumSegmentI-`

dAlloc is large enough to cover frame resolution with blocks of size SegmentIdBlockSize. Otherwise the segmentation map will be discarded.

mfxU8 *SegmentId

Pointer to the segmentation map buffer which holds the array of segment_ids in raster scan order. The application is responsible for allocation and release of this memory. The buffer pointed to by SegmentId, provided during initialization or Reset call should be considered in use until another SegmentId is provided via Reset call (if any), or until MFXVideoENCODE_Close is called. The buffer pointed to by SegmentId provided with *mfxEncodeCtrl* should be considered in use while the input surface is locked by the library. Every segment_id in the map should be in the range of 0 to NumSegments-1. If some segment_id is out of valid range, the segmentation map cannot be applied. If the *mfxExtVP9Segmentation* buffer is attached to the *mfxEncodeCtrl* structure in runtime, SegmentId can be zero. In this case, the segmentation map from static configuration will be used.

mfxExtVP9TemporalLayers

struct **mfxExtVP9TemporalLayers**

API allows the encoding of VP9 bitstreams that contain several subset bitstreams that differ in frame rates, also called “temporal layers”.

When decoding, each temporal layer can be extracted from the coded stream and decoded separately. The *mfxExtVP9TemporalLayers* structure configures the temporal layers for the VP9 encoder. It can be attached to the *mfxVideoParam* structure during initialization or the MFXVideoENCODE_Reset call. If the *mfx-ExtVP9TemporalLayers* buffer isn’t attached during initialization, temporal scalability is disabled. If the buffer isn’t attached for the Reset call, the encoder continues to use the temporal scalability configuration that was defined before the Reset call.

In the API, temporal layers are ordered by their frame rates in ascending order. Temporal layer 0 (having the lowest frame rate) is called the base layer. Each subsequent temporal layer includes all previous layers.

The temporal scalability feature requires a minimum number of allocated reference frames (controlled by the NumRefFrame parameter). If the NumRefFrame value set by the application isn’t enough to build the reference structure for the requested number of temporal layers, the library corrects the NumRefFrame value. The temporal layer structure is reset (re-started) after key-frames.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VP9_TEMPORAL_LAYERS.

mfxVP9TemporalLayer Layer[8]

The array of temporal layers. Layer[0] specifies the base layer.

The library reads layers from the array when they are defined (FrameRateScale > 0). All layers starting from first layer with FrameRateScale = 0 are ignored. The last layer that is not ignored is considered the “highest layer”.

The frame rate of the highest layer is specified in the *mfxVideoParam* structure. Frame rates of lower layers are calculated using their FrameRateScale.

TargetKbps of the highest layer should be equal to the TargetKbps value specified in the *mfxVideoParam* structure. If it is not true, TargetKbps of highest temporal layers has priority.

If there are no defined layers in the Layer array, the temporal scalability feature is disabled. For example, to disable temporal scalability in runtime, the application should pass *mfExtVP9TemporalLayers* buffer to Reset with all FrameRateScales set to 0.

mfQPandMode

struct **mfQPandMode**

Specifies per-MB or per-CU mode and QP or DeltaQP value depending on the mode type.

Public Members

mfU8 QP

QP for MB or CU. Valid when Mode = MFX_MBQP_MODE_QP_VALUE.

For AVC, the valid range is 1 to 51.

For HEVC, the valid range is 1 to 51. The application's provided QP values should be valid, otherwise invalid QP values may cause undefined behavior.

MBQP map should be aligned for 16x16 block size. The align rule is: (width +15 /16) && (height +15 /16).

For MPEG2, the valid range is 1 to 112. QP corresponds to quantizer_scale of the ISO*VIEC* 13818-2 specification.

mfI8 DeltaQP

Per-macroblock QP delta. Valid when Mode = MFX_MBQP_MODE_QP_DELTA.

mfU16 Mode

Defines QP update mode. Can be equal to MFX_MBQP_MODE_QP_VALUE or MFX_MBQP_MODE_QP_DELTA.

mfVP9TemporalLayer

struct **mfVP9TemporalLayer**

Specifies temporal layer.

Public Members

mfU16 FrameRateScale

The ratio between the frame rates of the current temporal layer and the base layer. The library treats a particular temporal layer as "defined" if it has FrameRateScale > 0. If the base layer is defined, it must have FrameRateScale = 1. FrameRateScale of each subsequent layer (if defined) must be a multiple of and greater than the FrameRateScale value of previous layer.

mfU16 TargetKbps

Target bitrate for the current temporal layer. Ignored if RateControlMethod is CQP. If RateControlMethod is not CQP, the application must provide TargetKbps for every defined temporal layer. TargetKbps of each subsequent layer (if defined) must be greater than the TargetKbps value of the previous layer.

mfxTemporalLayer

struct **mfxTemporalLayer**

The structure is used for universal temporal layer description.

Public Members

mfxU16 **FrameRateScale**

The ratio between the frame rates of the current temporal layer and the base layer. The library treats a particular temporal layer as “defined” if it has `FrameRateScale > 0`. If the base layer is defined, it must have `FrameRateScale = 1`. `FrameRateScale` of each subsequent layer (if defined) must be a multiple of and greater than the `FrameRateScale` value of previous layer.

mfxU16 **reserved[3]**

Reserved for future use.

mfxU32 **InitialDelayInKB**

Initial size of the Video Buffering Verifier (VBV) buffer for the current temporal layer.

Note: In this context, KB is 1000 bytes and Kbps is 1000 bps.

mfxU32 **BufferSizeInKB**

Represents the maximum possible size of any compressed frames for the current temporal layer.

mfxU32 **TargetKbps**

Target bitrate for the current temporal layer. If `RateControlMethod` is not CQP, the application can provide `TargetKbps` for every defined temporal layer. If `TargetKbps` per temporal layer is not set then encoder doesn't apply any special bitrate limitations for the layer.

mfxU32 **MaxKbps**

The maximum bitrate at which the encoded data enters the Video Buffering Verifier (VBV) buffer for the current temporal layer.

mfxU32 **reserved1[16]**

Reserved for future use.

mfxI32 **QPI**

Quantization Parameter (QP) for I-frames for constant QP mode (CQP) for the current temporal layer. Zero QP is not valid and means that the default value is assigned by the library. Non-zero QPI might be clipped to supported QPI range.

Note: Default QPI value is implementation dependent and subject to change without additional notice in this document.

mfxI32 **QPP**

Quantization Parameter (QP) for P-frames for constant QP mode (CQP) for the current temporal layer. Zero

QP is not valid and means that the default value is assigned by the library. Non-zero QPP might be clipped to supported QPI range.

Note: Default QPP value is implementation dependent and subject to change without additional notice in this document.

mfxI32 **QPB**

Quantization Parameter (QP) for B-frames for constant QP mode (CQP) for the current temporal layer. Zero QP is not valid and means that the default value is assigned by the library. Non-zero QPI might be clipped to supported QPB range.

Note: Default QPB value is implementation dependent and subject to change without additional notice in this document.

mfxU16 **reserved2[4]**

Reserved for future use.

mfxExtTemporalLayers

struct **mfxExtTemporalLayers**

The structure is used for universal temporal layers description.

Public Members

mfxU16 **NumLayers**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_UNIVERSAL_TEMPORAL_LAYERS. The number of temporal layers.

mfxU16 **BaseLayerPID**

The priority ID of the base layer. The encoder increases the ID for each temporal layer and writes to the prefix NAL unit for AVC and HEVC.

mfxU16 **reserved[2]**

Reserved for future use.

mfxTemporalLayer ***Layers**

The array of temporal layers.

mfxU16 **reserved1[8]**

Reserved for future use.

mfExtAV1BitstreamParam

struct **mfExtAV1BitstreamParam**

The structure is used by AV1 encoder with more parameter control to encode frame.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AV1_BITSTREAM_PARAM.

mfU16 WriteIVFHeaders

Tri-state option to control IVF headers insertion, default is ON. Writing IVF headers is enabled in the encoder when *mfExtAV1BitstreamParam* is attached and its value is ON or zero. Writing IVF headers is disabled by default in the encoder when *mfExtAV1BitstreamParam* is not attached.

mfExtAV1ResolutionParam

struct **mfExtAV1ResolutionParam**

The structure is used by AV1 encoder with more parameter control to encode frame.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AV1_RESOLUTION_PARAM.

mfU32 FrameWidth

Width of the coded frame in pixels, default value is from *mfFrameInfo*.

mfU32 FrameHeight

Height of the coded frame in pixels, default value is from *mfFrameInfo*.

mfExtAV1TileParam

struct **mfExtAV1TileParam**

The structure is used by AV1 encoder with more parameter control to encode frame.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AV1_TILE_PARAM.

mfU16 NumTileRows

Number of tile rows, default value is 1.

mfXU16 NumTileColumns

Number of tile columns, default value is 1.

mfXU16 NumTileGroups

Number of tile groups, it will be ignored if the tile groups num is invalid, default value is 1.

mfXExtAV1Segmentation**struct mfXExtAV1Segmentation**

In the AV1 encoder it is possible to divide a frame into up to 8 segments and apply particular features (like delta for quantization index or for loop filter level) on a per-segment basis. “Uncompressed header” of every frame indicates if segmentation is enabled for the current frame, and (if segmentation enabled) contains full information about features applied to every segment. Every “Mode info block” of a coded frame has `segment_id` in the range of 0 to 7. To enable Segmentation, the *mfXExtAV1Segmentation* structure with correct settings should be passed to the encoder. It can be attached to the *mfXVideoParam* structure during initialization or the MFXVideoENCODE_Reset call (static configuration). If the *mfXExtAV1Segmentation* buffer isn’t attached during initialization, segmentation is disabled for static configuration. If the buffer isn’t attached for the Reset call, the encoder continues to use static configuration for segmentation which was the default before this Reset call. If the *mfXExtAV1Segmentation* buffer with NumSegments=0 is provided during initialization or Reset call, segmentation becomes disabled for static configuration. The buffer can be attached to the *mfXEncodeCtrl* structure during runtime (dynamic configuration). Dynamic configuration is applied to the current frame only. After encoding of the current frame, the encoder will switch to the next dynamic configuration or to static configuration if dynamic configuration is not provided for next frame). The SegmentIdBlockSize, NumSegmentIdAlloc, and SegmentId parameters represent a segmentation map. Here, the segmentation map is an array of `segment_ids` (one byte per `segment_id`) for blocks of size NxN in raster scan order. The size NxN is specified by the application and is constant for the whole frame. If *mfXExtAV1Segmentation* is attached during initialization and/or during runtime, all three parameters should be set to proper values that do not conflict with each other and with NumSegments. If any of the parameters are not set or any conflict or error in these parameters is detected by the library, the segmentation map will be discarded.

Public Members***mfXExtBuffer Header***

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_AV1_SEGMENTATION.

mfXU8 NumSegments

Number of segments for frame. Value 0 means that segmentation is disabled. Sending 0 for a particular frame will disable segmentation for this frame only. Sending 0 to the Reset API function will disable segmentation permanently. Segmentation can be enabled again by a subsequent Reset call.

mfXAV1SegmentParam Segment[8]

Array of mfXAV1SegmentParam structures containing features and parameters for every segment. Entries with indexes bigger than NumSegments-1 are ignored. See the mfXAV1SegmentParam structure for definitions of segment features and their parameters.

mfXU16 SegmentIdBlockSize

Size of block (NxN) for segmentation map. See AV1 SegmentIdBlockSize enumerator for values for this option. An encoded block that is bigger than AV1 SegmentIdBlockSize uses `segment_id` taken from it’s top-left sub-block from the segmentation map. The application can check if a particular block size is supported by calling Query.

***mfxU32* NumSegmentIdAlloc**

Size of buffer allocated for segmentation map (in bytes). Application must assure that NumSegmentIdAlloc is large enough to cover frame resolution with blocks of size SegmentIdBlockSize. Otherwise the segmentation map will be discarded.

***mfxU8* *SegmentIds**

Pointer to the segmentation map buffer which holds the array of segment_ids in raster scan order. The application is responsible for allocation and release of this memory. The buffer pointed to by SegmentId, provided during initialization or Reset call should be considered in use until another SegmentId is provided via Reset call (if any), or until MFXVideoENCODE_Close is called. The buffer pointed to by SegmentId provided with *mfxEncodeCtrl* should be considered in use while the input surface is locked by the library. Every segment_id in the map should be in the range of 0 to NumSegments-1. If some segment_id is out of valid range, the segmentation map cannot be applied. If the *mfxExtAV1Segmentation* buffer is attached to the *mfxEncodeCtrl* structure in runtime, SegmentId can be zero. In this case, the segmentation map from static configuration will be used.

mfxCTUHeader

struct **mfxCTUHeader**

Public Members***mfxU32* CUcountminus1**

Number of CU per CTU.

***mfxU32* MaxDepth**

Max quad-tree depth of CU in CTU.

***mfxU16* CurrXAddr**

Horizontal address of CTU.

***mfxU16* CurrYAddr**

Vertical address of CTU.

mfxCUInfo

struct **mfxCUInfo**

Public Members

mfxU32 **CU_Size**

indicates the CU size of the current CU. 0: 8x8 1: 16x16 2: 32x32 3: 64x64

mfxU32 **CU_pred_mode**

indicates the prediction mode for the current CU. 0: intra 1: inter

mfxU32 **CU_part_mode**

indicates the PU partition mode for the current CU. 0: 2Nx2N 1: 2NxN (inter) 2: Nx2N (inter) 3: NXN (intra only, CU Size=8x8 only. Luma Intra Mode indicates the intra prediction mode for 4x4_0. The additional prediction modes are overloaded on 4x4_1, 4x4_2, 4x4_3 below) 4: 2NxnT (inter only) 5: 2NxnB (inter only) 6: nLx2N (inter only) 7: nRx2N (inter only).

mfxU32 **InterPred_IDC_MV0**

indicates the prediction direction for PU0 of the current CU. 0: L0 1: L1 2: Bi 3: reserved

mfxU32 **InterPred_IDC_MV1**

indicates the prediction direction for PU1 of the current CU. 0: L0 1: L1 2: Bi 3: reserved

mfxU32 **LumaIntraMode**

Final explicit Luma Intra Mode 4x4_0 for NxN. Valid values 0..34 Note: CU_part_mode==NxN.

mfxU32 **ChromaIntraMode**

indicates the final explicit Luma Intra Mode for the CU. 0: DM (use Luma mode, from block 0 if NxN) 1: reserved 2: Planar 3: Vertical 4: Horizontal 5: DC

mfxU32 **LumaIntraMode4x4_1**

Final explicit Luma Intra Mode 4x4_1. Valid values 0..34 Note: CU_part_mode==NxN.

mfxU32 **LumaIntraMode4x4_2**

Final explicit Luma Intra Mode 4x4_2. Valid values 0..34 Note: CU_part_mode==NxN.

mfxU32 **LumaIntraMode4x4_3**

Final explicit Luma Intra Mode 4x4_3. Valid values 0..34 Note: CU_part_mode==NxN.

mfxU32 **SAD**

distortion measure, approximation to SAD.

Will deviate significantly (pre, post reconstruction) and due to variation in algorithm.

mfxI16Pair **MV[2][2]**

These parameters indicate motion vectors that are associated with the PU0/PU1 winners range [-2048.00..2047.75]. L0/PU0 - MV[0][0] L0/PU1 - MV[0][1] L1/PU0 - MV[1][0] L1/PU1 - MV[1][1]

mfxU32 **L0_MV0_RefID**

This parameter indicates the reference index associated with the MV X/Y that is populated in the L0_MV0.X and L0_MV0.Y fields.

mfxU32 **L0_MV1_RefID**

This parameter indicates the reference index associated with the MV X/Y that is populated in the

L0_MV1.X and L0_MV1.Y fields.

mfXU32 **L1_MV0_RefID**

This parameter indicates the reference index associated with the MV X/Y that is populated in the L1_MV0.X and L1_MV0.Y fields.

mfXU32 **L1_MV1_RefID**

This parameter indicates the reference index associated with the MV X/Y that is populated in the L1_MV1.X and L1_MV1.Y fields.

mfXCTUInfo

struct **mfXCTUInfo**

Public Members

mfXCTUHeader **CtuHeader**

H.265 CTU header.

mfXCUIInfo **CuInfo**[64]

Array of CU.

mfXMBInfo

struct **mfXMBInfo**

The structure describes H.264 stats per MB.

Public Members

mfXU32 **MbType**

Together with **IntraMbFlag** this parameter specifies macroblock type according to the ISO*VIEC* 14496-10 with the following difference - it stores either intra or inter values according to **IntraMbFlag**, but not intra after inter. Values for P-slices are mapped to B-slice values. For example P_16x8 is coded with B_FWD_16x8 value.

mfXU32 **InterMBMode**

This field specifies inter macroblock mode and is ignored for intra MB. It is derived from **MbType** and has next values:

- 0 - 16x16 mode
- 1 - 16x8 mode
- 2 - 8x16 mode
- 3 - 8x8 mode

***mfXU32* IntraMBMode**

This field specifies intra macroblock mode and is ignored for inter MB. It is derived from MbType and has next values:

- 0 - 16x16 mode
- 1 - 8x8 mode
- 2 - 4x4 mode
- 3 - PCM

***mfXU32* IntraMBFlag**

This flag specifies intra/inter MB type and has next values: 0 - Inter prediction MB type 1 - Intra prediction MB type

***mfXU32* SubMBSHapes**

This field specifies subblock shapes for the current MB. Each block is described by 2 bits starting from lower bits for block 0.

- 0 - 8x8
- 1 - 8x4
- 2 - 4x8
- 3 - 4x4

***mfXU32* SubMBSHapeMode**

This field specifies prediction modes for the current MB partition blocks. Each block is described by 2 bits starting from lower bits for block 0.

- 0 - Pred_L0
- 1 - Pred_L1
- 2 - BiPred
- 3 - reserved

Only one prediction value for partition is reported, the rest values are set to zero. For example:

- 16x16 Pred_L1 - 0x01 (only 2 lower bits are used)
- 16x8 Pred_L1 / BiPred - 0x09 (1001b)
- 8x16 BiPred / BiPred - 0x0a (1010b)

For P MBs this value is always zero.

***mfXU32* ChromaIntraPredMode**

This value specifies chroma intra prediction mode.

- 0 - DC
- 1 - Horizontal
- 2 - Vertical
- 3 - Plane

***mfxU32* SAD**

Distortion measure, approximation to SAD.

Deviate significantly (pre, post reconstruction) and due to variation in algorithm.

***mfxI8* Qp**
MB QP.***mfxU16* LumaIntraMode[4]**

These values specify luma intra prediction modes for current MB. Each element of the array corresponds to 8x8 block and each holds prediction modes for four 4x4 subblocks. Four bits per mode, lowest bits for left top subblock. All 16 prediction modes are always specified. For 8x8 case, block prediction mode is populated to all subblocks of the 8x8 block. For 16x16 case - to all subblocks of the MB.

Prediction directions for 4x4 and 8x8 blocks:

- 0 - Vertical
- 1 - Horizontal
- 2 - DC
- 3 - Diagonal Down Left
- 4 - Diagonal Down Right
- 5 - Vertical Right
- 6 - Horizontal Down
- 7 - Vertical Left
- 8 - Horizontal Up

Prediction directions for 16x16 blocks:

- 0 - Vertical
- 1 - Horizontal
- 2 - DC
- 3 - Plane

mfxEncodeBlkStats

struct **mfxEncodeBlkStats**

The structure describes H.264 and H.265 stats per MB or CTUs.

Public Members

mfxF32 **NumMB**

Number of MBs per frame for H.264.

mfxF32 **NumCTU**

number of CTUs per frame for H.265.

mfxF32 **CTUInfo *HEVCCTUArray**

Array of CTU statistics.

mfxF32 **MBInfo *AVCMBArray**

Array of MB statistics.

mfxF32EncodeHighLevelStats

struct **mfxF32EncodeHighLevelStats**

The structure describes H.264/H.265 frame/slice/tile level statistics.

Public Members

mfxF32 **PSNRLuma**

PSNR for LUMA samples.

mfxF32 **PSNRCb**

PSNR for Chroma (Cb) samples.

mfxF32 **PSNRCr**

PSNR for Chroma (Cr) samples.

mfxF64 **SADLuma**

distortion measure, approximation to SAD.

Will deviate significantly (pre, post reconstruction) and due to variation in algorithm.

mfxF32 **NumMB**

Number of MBs per frame for H.264.

mfxF32 **NumCTU**

number of CTUs per frame for H.265.

mfxF32 **NumIntraBlock**

For H.264 it is always 16x16 corresponding to MB size. In H.265 it's normalized to 4x4, so for each CU we calculate number of 4x4 which belongs to the block.

mfxF32 **NumInterBlock**

Number of intra blocks in the frame. The size of block is defined by BlockSize. For H.265 it can be more than number of intra CU.

***mfxU32* NumSkippedBlock**

Number of inter blocks in the frame. The size of block is defined by BlockSize. For H.265 it can be more than number of inter CU.

***mfxU32* reserved[8]**

Number of skipped blocks in the frame. The size of block is defined by BlockSize. For H.265 it can be more than number of skipped CU.

mfxEncodeFrameStats

typedef *mfxEncodeHighLevelStats* **mfxEncodeFrameStats**

Alias for the structure to describe H.264 and H.265 frame level stats.

mfxEncodeSliceStats

struct **mfxEncodeSliceStats**

The structure describes H.264 and H.265 stats per Slice or Tile.

Public Members***mfxU32* NumElements**

Number of Slices or Tiles per frame for H.264/H.265.

***mfxEncodeHighLevelStats* *HighLevelStatsArray**

Array of CTU statistics.

mfxEncodeTileStats

typedef *mfxEncodeSliceStats* **mfxEncodeTileStats**

Alias for the structure to describe H.264 and H.265 tile level stats.

mfxEncodeStatsContainer

struct **mfxEncodeStatsContainer**

The structure represents reference counted container for output after encoding operation which includes statistics and synchronization primitive for compressed bitstream. The memory is allocated and released by the library.

Public Members

mfxFStructVersion **Version**

The version of the structure.

mfxFStatus (***SynchronizeStatistics**)(*mfxFRefInterface* *ref_interface, *mfxFU32* wait)

Guarantees readiness of the statistics after a function completes. Instead of `MFXVideoCORE_SyncOperation` which leads to the synchronization of all output objects, users may directly call the `mfxFEncodeStatsContainer::SynchronizeStatistics` function to get output statistics.

< Reference counting interface.

Parameters

- **ref_interface** – [in] Valid interface.
- **wait** – [out] Wait time in milliseconds.

Returns

`MFX_ERR_NONE` If no error.

`MFX_ERR_NULL_PTR` If interface is `NULL`.

`MFX_ERR_INVALID_HANDLE` If any of container is not valid object .

`MFX_WRN_IN_EXECUTION` If the given timeout is expired and the container is not ready.

`MFX_ERR_ABORTED` If the specified asynchronous function aborted due to data dependency on a previous asynchronous function that did not complete.

`MFX_ERR_UNKNOWN` Any internal error.

mfxFStatus (***SynchronizeBitstream**)(*mfxFRefInterface* *ref_interface, *mfxFU32* wait)

Guarantees readiness of associated compressed bitstream after a function completes. Instead of `MFXVideoCORE_SyncOperation` which leads to the synchronization of all output objects, users may directly call the `mfxFEncodeStatsContainer::SynchronizeStatistics` function to get output bitstream.

Parameters

- **ref_interface** – [in] Valid interface.
- **wait** – [out] Wait time in milliseconds.

Returns

`MFX_ERR_NONE` If no error.

`MFX_ERR_NULL_PTR` If interface is `NULL`.

`MFX_ERR_INVALID_HANDLE` If any of container is not valid object .

`MFX_WRN_IN_EXECUTION` If the given timeout is expired and the container is not ready.

`MFX_ERR_ABORTED` If the specified asynchronous function aborted due to data dependency on a previous asynchronous function that did not complete.

`MFX_ERR_UNKNOWN` Any internal error.

mfExtEncodeStatsOutput

struct **mfExtEncodeStatsOutput**

The extension buffer which should be attached by application for *mfBitstream* buffer before encode operation. As result the encoder will allocate memory for statistics and fill appropriate structures.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ENCODESTATS_BLK.

mfEncodeStatsMode **Mode**

What statistics is required: block/slice/tile/frame level or any combinations. In case of slice or tile output statistics for one slice or tile will be available only. What encoding mode should be used to gather statistics.

mfEncodeStatsContainer ***EncodeStatsContainer**

encode output, filled by the implementation.

mfExtHEVCRefListCtrl

typedef *mfExtAVCRefListCtrl* **mfExtHEVCRefListCtrl**

mfExtHEVCRefLists

typedef *mfExtAVCRefLists* **mfExtHEVCRefLists**

mfExtHEVCTemporalLayers

typedef *mfExtAvcTemporalLayers* **mfExtHEVCTemporalLayers**

VPP Structures

Structures used by VPP only.

API

- *mfExtColorConversion*
- *mfExtDecVideoProcessing*
- *mfExtEncodedSlicesInfo*
- *mfExtVppAuxData*
- *mfExtVPPColorFill*

- *mfExtVPPComposite*

mfExtColorConversion

struct **mfExtColorConversion**

A hint structure that tunes the VPP Color Conversion algorithm when attached to the *mfVideoParam* structure during VPP Init.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_COLOR_CONVERSION.

mfxU16 ChromaSiting

See ChromaSiting enumerator for details.

ChromaSiting is applied on input or output surface depending on the scenario:

VPP Input	VPP Output	ChromaSiting Indicates
MFX_CHROMAFORMAT_YUV420 MFX_CHROMAFORMAT_YUV422	MFX_CHROMAFORMAT_YUV444	Chroma location for input
MFX_CHROMAFORMAT_YUV444	MFX_CHROMAFORMAT_YUV420 MFX_CHROMAFORMAT_YUV422	Chroma location for output
MFX_CHROMAFORMAT_YUV420	MFX_CHROMAFORMAT_YUV420	Chroma location for input and output
MFX_CHROMAFORMAT_YUV420	MFX_CHROMAFORMAT_YUV422	Horizontal location for input and output, vertical location for input

mfxExtDecVideoProcessing

struct *mfxExtDecVideoProcessing*

If attached to the *mfxVideoParam* structure during the Init stage, this buffer will instruct the decoder to resize output frames via the fixed function resize engine (if supported by hardware), utilizing direct pipe connection and bypassing intermediate memory operations. The main benefits of this mode of pipeline operation are offloading resize operation to a dedicated engine, thus reducing power consumption and memory traffic.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_DEC_VIDEO_PROCESSING.

struct *mfxExtDecVideoProcessing::mfxIn* **In**

Input surface description.

struct *mfxExtDecVideoProcessing::mfxOut* **Out**

Output surface description.

struct **mfxIn**

Input surface description.

Public Members*mfXU16* **CropX**

X coordinate of region of interest of the input surface.

mfXU16 **CropY**

Y coordinate of region of interest of the input surface.

mfXU16 **CropW**

Width coordinate of region of interest of the input surface.

mfXU16 **CropH**

Height coordinate of region of interest of the input surface.

struct **mfXOut**

Output surface description.

Public Members*mfXU32* **FourCC**

FourCC of output surface Note: Should be MFX_FOURCC_NV12.

mfXU16 **ChromaFormat**

Chroma Format of output surface.

Note: Should be MFX_CHROMAFORMAT_YUV420

mfXU16 **Width**

Width of output surface.

mfXU16 **Height**

Height of output surface.

mfXU16 **CropX**

X coordinate of region of interest of the output surface.

mfXU16 **CropY**

Y coordinate of region of interest of the output surface.

mfXU16 **CropW**

Width coordinate of region of interest of the output surface.

mfXU16 **CropH**

Height coordinate of region of interest of the output surface.

mfExtEncodedSlicesInfo

struct **mfExtEncodedSlicesInfo**

Used by the encoder to report additional information about encoded slices. The application can attach this buffer to the *mfBitstream* structure before calling the MFXVideoENCODE_EncodeFrameAsync function.

Note: Not all implementations of the encoder support this extended buffer. The application must use query mode 1 to determine if the functionality is supported. To do this, the application must attach this extended buffer to the *mfVideoParam* structure and call the MFXVideoENCODE_Query function. If the function returns MFX_ERR_NONE, then the functionality is supported.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_ENCODED_SLICES_INFO.

mfU16 SliceSizeOverflow

When *mfExtCodingOption2::MaxSliceSize* is used, indicates the requested slice size was not met for one or more generated slices.

mfU16 NumSliceNonCompliant

When *mfExtCodingOption2::MaxSliceSize* is used, indicates the number of generated slices exceeds specification limits.

mfU16 NumEncodedSlice

Number of encoded slices.

mfU16 NumSliceSizeAlloc

SliceSize array allocation size. Must be specified by application.

mfU16 *SliceSize

Slice size in bytes. Array must be allocated by application.

mfExtVppAuxData

struct **mfExtVppAuxData**

Returns auxiliary data generated by the video processing pipeline. The encoding process may use the auxiliary data by attaching this structure to the *mfEncodeCtrl* structure.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_AUXDATA.

mfxU16 PicStruct

Detected picture structure - top field first, bottom field first, progressive or unknown if video processor cannot detect picture structure. See the PicStruct enumerator for definition of these values.

mfxU16 RepeatedFrame

The flag signals that the frame is identical to the previous one.

mfxExtVPPColorFill

struct **mfxExtVPPColorFill**

Configures the VPP ColorFill filter algorithm.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_COLORFILL.

mfxU16 Enable

Set to ON makes VPP fill the area between Width/Height and Crop borders. See the CodingOptionValue enumerator for values of this option.

mfxExtVPPComposite

struct **mfxExtVPPComposite**

Used to control composition of several input surfaces in one output. In this mode, the VPP skips any other filters. The VPP returns an error if any mandatory filter is specified and returns the filter skipped warning if an optional filter is specified. The only supported filters are deinterlacing and interlaced scaling. The only supported combinations of input and output color formats are:

- RGB to RGB,
- NV12 to NV12,
- RGB and NV12 to NV12, for per the pixel alpha blending use case.

The VPP returns MFX_ERR_MORE_DATA for additional input until an output is ready. When the output is ready, the VPP returns MFX_ERR_NONE. The application must process the output frame after synchronization.

The composition process is controlled by:

- mfxFrameInfo::CropXYWH in the input surface defines the location of the picture in the input frame.
- InputStream[i].DstXYWH defines the location of the cropped input picture in the output frame.

- `mfxFrameInfo::CropXYWH` in the output surface defines the actual part of the output frame. All pixels in the output frame outside this region will be filled by the specified color.

If the application uses the composition process on video streams with different frame sizes, the application should provide maximum frame size in the `mfxVideoParam` structure during the initialization, reset, or query operations.

If the application uses the composition process, the `MFXVideoVPP_QueryIOSurf` function returns the cumulative number of input surfaces, that is, the number required to process all input video streams. The function sets the frame size in the `mfxFrameAllocRequest` equal to the size provided by the application in the `mfxVideoParam` structure.

The composition process supports all types of surfaces.

All input surfaces should have the same type and color format, except for the per pixel alpha blending case, where it is allowable to mix NV12 and RGB surfaces.

There are three different blending use cases:

- **Luma keying.** All input surfaces should have the NV12 color format specified during VPP initialization. Part of each surface, including the first one, may be rendered transparent by using `LumaKeyEnable`, `LumaKeyMin`, and `LumaKeyMax` values.
- **Global alpha blending.** All input surfaces should have the same color format, NV12 or RGB, specified during VPP initialization. Each input surface, including the first one, can be blended with underlying surfaces by using `GlobalAlphaEnable` and `GlobalAlpha` values.
- **Per-pixel alpha blending.** It is allowed to mix NV12 and RGB input surfaces. Each RGB input surface, including the first one, can be blended with underlying surfaces by using `PixelAlphaEnable` value.

It is not allowed to mix different blending use cases in the same function call.

In the special case where the destination region of the output surface defined by output crops is fully covered with destination sub-regions of the surfaces, the fast compositing mode can be enabled. The main use case for this mode is a video-wall scenario with a fixed destination surface partition into sub-regions of potentially different size.

In order to trigger this mode, the application must cluster input surfaces into tiles, defining at least one tile by setting the `NumTiles` field to be greater than 0, and assigning surfaces to the corresponding tiles by setting the `TileId` field to the value within the 0 to `NumTiles` range per input surface. Tiles should also satisfy the following additional constraints:

- Each tile should not have more than 8 surfaces assigned to it.
- Tile bounding boxes, as defined by the enclosing rectangles of a union of a surfaces assigned to this tile, should not intersect.

Background color may be changed dynamically through `Reset`. There is no default value. YUV black is (0;128;128) or (16;128;128) depending on the sample range. The library uses a YUV or RGB triple depending on output color format.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_COMPOSITE.

mfU16 Y

Y value of the background color.

mfU16 R

R value of the background color.

mfU16 U

U value of the background color.

mfU16 G

G value of the background color.

mfU16 V

V value of the background color.

mfU16 B

B value of the background color.

mfU16 NumTiles

Number of input surface clusters grouped together to enable fast compositing. May be changed dynamically at runtime through Reset.

mfU16 NumInputStream

Number of input surfaces to compose one output. May be changed dynamically at runtime through Reset. Number of surfaces can be decreased or increased, but should not exceed the number specified during initialization. Query mode 2 should be used to find the maximum supported number.

mfVPPCompInputStream *InputStream

An array of *mfVPPCompInputStream* structures that describe composition of input video streams. It should consist of exactly NumInputStream elements.

mfExtVPPDeinterlacing

struct **mfExtVPPDeinterlacing**

Used by the application to specify different deinterlacing algorithms.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_DEINTERLACING.

mfU16 Mode

Deinterlacing algorithm. See the DeinterlacingMode enumerator for details.

mfU16 TelecinePattern

Specifies telecine pattern when Mode = MFX_DEINTERLACING_FIXED_TELECINE_PATTERN. See the TelecinePattern enumerator for details.

mfU16 TelecineLocation

Specifies position inside a sequence of 5 frames where the artifacts start when TelecinePattern = MFX_TELECINE_POSITION_PROVIDED

mfU16 reserved[9]

Reserved for future use.

mfExtVPPDenoise

struct **mfExtVPPDenoise**

A hint structure that configures the VPP denoise filter algorithm.

Deprecated:

Deprecated in API version 2.5. Use *mfExtVPPDenoise2* instead.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_DENOISE.

mfU16 DenoiseFactor

Indicates the level of noise to remove. Value range of 0 to 100 (inclusive).

mfExtVPPDenoise2

struct **mfExtVPPDenoise2**

A hint structure that configures the VPP denoise filter algorithm.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_DENOISE2.

mfxDenoiseMode Mode

Indicates the mode of denoise. mfxDenoiseMode enumerator.

mfU16 Strength

Denoise strength in manual mode. Value of 0-100 (inclusive) indicates the strength of denoise. The strength of denoise controls degree of possible changes of pixel values; the bigger the strength the larger the change is.

mfU16 reserved[15]

mfExtVPPDetail

struct **mfExtVPPDetail**

A hint structure that configures the VPP detail/edge enhancement filter algorithm.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_DETAIL.

mfU16 DetailFactor

Indicates the level of details to be enhanced. Value range of 0 to 100 (inclusive).

mfExtVPPDoNotUse

struct **mfExtVPPDoNotUse**

Tells the VPP not to use certain filters in pipeline. See “Configurable VPP filters” table for complete list of configurable filters. The user can attach this structure to the *mfVideoParam* structure when initializing video processing.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_DONOTUSE.

mfxU32 NumAlg

Number of filters (algorithms) not to use

mfxU32 *AlgList

Pointer to a list of filters (algorithms) not to use

mfxExtVPPDoUse

struct **mfxExtVPPDoUse**

Tells the VPP to include certain filters in the pipeline.

Each filter may be included in the pipeline in one of two different ways:

- Adding a filter ID to this structure. In this method, the default filter parameters are used.
- Attaching a filter configuration structure directly to the *mfxVideoParam* structure. In this method, adding filter ID to the *mfxExtVPPDoUse* structure is optional.

See Table “Configurable VPP filters” for complete list of configurable filters, their IDs, and configuration structures.

The user can attach this structure to the *mfxVideoParam* structure when initializing video processing.

Note: MFX_EXTBUFF_VPP_COMPOSITE cannot be enabled using *mfxExtVPPDoUse* because default parameters are undefined for this filter. The application must attach the appropriate filter configuration structure directly to the *mfxVideoParam* structure to enable it.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_DOUSE.

mfxU32 NumAlg

Number of filters (algorithms) to use

mfxU32 *AlgList

Pointer to a list of filters (algorithms) to use

mfExtVPPFieldProcessing

struct **mfExtVPPFieldProcessing**

Configures the VPP field processing algorithm. The application can attach this extended buffer to the *mfVideoParam* structure to configure initialization and/or to the *mfFrameData* during runtime. Runtime configuration has priority over initialization configuration. If the field processing algorithm was activated via the *mfExtVPPDoUse* structure and the *mfExtVPPFieldProcessing* extended buffer was not provided during initialization, this buffer must be attached to the *mfFrameData* structure of each input surface.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_FIELD_PROCESSING.

mfU16 Mode

Specifies the mode of the field processing algorithm. See the VPPFieldProcessingMode enumerator for values of this option.

mfU16 InField

When Mode is MFX_VPP_COPY_FIELD, specifies input field. See the PicType enumerator for values of this parameter.

mfU16 OutField

When Mode is MFX_VPP_COPY_FIELD, specifies output field. See the PicType enumerator for values of this parameter.

mfExtVPPFrameRateConversion

struct **mfExtVPPFrameRateConversion**

Configures the VPP frame rate conversion filter. The user can attach this structure to the *mfVideoParam* structure when initializing, resetting, or querying capability of video processing.

On some platforms the advanced frame rate conversion algorithm (the algorithm based on frame interpolation) is not supported. To query its support, the application should add the MFX_FRCALGM_FRAME_INTERPOLATION flag to the Algorithm value in the *mfExtVPPFrameRateConversion* structure, attach it to the structure, and call the MFXVideoVPP_Query function. If the filter is supported, the function returns a MFX_ERR_NONE status and copies the content of the input structure to the output structure. If an advanced filter is not supported, then a simple filter will be used and the function returns MFX_WRN_INCOMPATIBLE_VIDEO_PARAM, copies content of the input structure to the output structure, and corrects the Algorithm value.

If advanced FRC algorithm is not supported, both MFXVideoVPP_Init and MFXVideoVPP_Reset functions return the MFX_WRN_INCOMPATIBLE_VIDEO_PARAM status.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_FRAME_RATE_CONVERSION.

mfxU16 Algorithm

See the FrcAlgm enumerator for a list of frame rate conversion algorithms.

mfxExtVPPImageStab

struct **mfxExtVPPImageStab**

A hint structure that configures the VPP image stabilization filter.

On some platforms this filter is not supported. To query its support, the application should use the same approach that it uses to configure VPP filters: adding the filter ID to the *mfxExtVPPDoUse* structure or by attaching the *mfxExtVPPImageStab* structure directly to the *mfxVideoParam* structure and calling the MFXVideoVPP_Query function.

If this filter is supported, the function returns a MFX_ERR_NONE status and copies the content of the input structure to the output structure. If the filter is not supported, the function returns MFX_WRN_FILTER_SKIPPED, removes the filter from the *mfxExtVPPDoUse* structure, and zeroes the *mfxExtVPPImageStab* structure.

If the image stabilization filter is not supported, both MFXVideoVPP_Init and MFXVideoVPP_Reset functions return a MFX_WRN_FILTER_SKIPPED status.

The application can retrieve the list of active filters by attaching the *mfxExtVPPDoUse* structure to the *mfxVideoParam* structure and calling the MFXVideoVPP_GetVideoParam function. The application must allocate enough memory for the filter list.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_IMAGE_STABILIZATION.

mfxU16 Mode

Image stabilization mode. See ImageStabMode enumerator for values.

mfxExtVppMctf

struct **mfxExtVppMctf**

Provides setup for the Motion-Compensated Temporal Filter (MCTF) during the VPP initialization and for control parameters at runtime. By default, MCTF is off. An application may enable it by adding MFX_EXTBUFF_VPP_MCTF to the *mfxExtVPPDoUse* buffer or by attaching *mfxExtVppMctf* to the *mfxVideoParam* structure during initialization or reset.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_MCTF.

mfxU16 FilterStrength

Value in range of 0 to 20 (inclusive) to indicate the filter strength of MCTF.

The strength of the MCTF process controls the degree of possible change of pixel values eligible for MCTF - the greater the strength value, the larger the change. It is a dimensionless quantity - values in the range of 1 to 20 inclusively imply strength; value 0 stands for AUTO mode and is valid during initialization or reset only

If an invalid value is given, it is fixed to the default value of 0. If the field value is in the range of 1 to 20 inclusive, MCTF operates in fixed-strength mode with the given strength of MCTF process.

At runtime, values of 0 and greater than 20 are ignored.

mfxExtVPPMirroring

struct **mfxExtVPPMirroring**

Configures the VPP Mirroring filter algorithm.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_MIRRORING.

mfxU16 Type

Mirroring type. See MirroringType for values.

mfxExtVPPProcAmp

struct **mfxExtVPPProcAmp**

A hint structure that configures the VPP ProcAmp filter algorithm. The structure parameters will be clipped to their corresponding range and rounded by their corresponding increment.

Note: There are no default values for fields in this structure, all settings must be explicitly specified every time this buffer is submitted for processing.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_PROCAMP.

mfxF64 Brightness

The brightness parameter is in the range of -100.0F to 100.0F, in increments of 0.1F. Setting this field to 0.0F will disable brightness adjustment.

mfxF64 Contrast

The contrast parameter in the range of 0.0F to 10.0F, in increments of 0.01F, is used for manual contrast adjustment. Setting this field to 1.0F will disable contrast adjustment. If the parameter is negative, contrast will be adjusted automatically.

mfxF64 Hue

The hue parameter is in the range of -180F to 180F, in increments of 0.1F. Setting this field to 0.0F will disable hue adjustment.

mfxF64 Saturation

The saturation parameter is in the range of 0.0F to 10.0F, in increments of 0.01F. Setting this field to 1.0F will disable saturation adjustment.

mfxExtVPPRotation

struct **mfxExtVPPRotation**

Configures the VPP Rotation filter algorithm.

Public Members

mfxExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_ROTATION.

mfxU16 Angle

Rotation angle. See Angle enumerator for supported values.

mfxExtVPPScaling

struct **mfxExtVPPScaling**

Configures the VPP Scaling filter algorithm. Not all combinations of ScalingMode and InterpolationMethod are supported in the library. The application must use the Query API function to determine if a combination is supported.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_SCALING.

mfU16 ScalingMode

Scaling mode. See ScalingMode for values.

mfU16 InterpolationMethod

Interpolation mode for scaling algorithm. See InterpolationMode for values.

mfChannel

struct **mfChannel**

A hint structure that configures the data channel.

Public Members

mfDataType DataType

Data type, mfDataType enumerator.

mfU32 Size

Size of Look up table, the number of elements per dimension.

mfU8 *Data

The pointer to 3DLUT data, 8 bit unsigned integer.

mfU16 *Data16

The pointer to 3DLUT data, 16 bit unsigned integer.

mfU32 reserved[4]

Reserved for future extension.

mf3DLutSystemBuffer

struct **mf3DLutSystemBuffer**

A hint structure that configures 3DLUT system buffer.

Public Members

mfXChannel **Channel**[3]
3 Channels, can be RGB or YUV, *mfXChannel* structure.

mfXU32 **reserved**[8]
Reserved for future extension.

mfX3DLutVideoBuffer

struct **mfX3DLutVideoBuffer**
A hint structure that configures 3DLUT video buffer.

Public Members

mfXDataType **DataType**
Data type, *mfXDataType* enumerator.

mfX3DLutMemoryLayout **MemLayout**
Indicates 3DLUT memory layout. *mfX3DLutMemoryLayout* enumerator.

mfXMemId **MemId**
Memory ID for holding the lookup table data. One MemID is dedicated for one instance of VPP.

mfXU32 **reserved**[8]
Reserved for future extension.

mfXExtVPP3DLut

struct **mfXExtVPP3DLut**
A hint structure that configures 3DLUT filter.

Public Members

mfXExtBuffer **Header**
Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_3DLUT..

mfX3DLutChannelMapping **ChannelMapping**
Indicates 3DLUT channel mapping. *mfX3DLutChannelMapping* enumerator.

mfXResourceType **BufferType**
Indicates 3DLUT buffer type. *mfXResourceType* enumerator, can be system memory, VA surface, DX11 texture/buffer etc.

mfX3DLutSystemBuffer **SystemBuffer**
The 3DLUT system buffer. *mfX3DLutSystemBuffer* structure describes the details of the buffer.

***mfx3DLutVideoBuffer* VideoBuffer**

The 3DLUT video buffer. *mfx3DLutVideoBuffer* describes the details of 3DLUT video buffer.

***mfxU32* reserved[4]**

Reserved for future extension.

mfxExtVPPVideoSignalInfostruct **mfxExtVPPVideoSignalInfo**

Used to control transfer matrix and nominal range of YUV frames. The application should provide this during initialization. Supported for multiple conversions, for example YUV to YUV, YUV to RGB, and RGB to YUV.

Note: This structure is used by VPP only and is not compatible with *mfxExtVideoSignalInfo*.

Public Members***mfxExtBuffer* Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_VPP_VIDEO_SIGNAL_INFO.

***mfxU16* TransferMatrix**

Transfer matrix.

***mfxU16* NominalRange**

Nominal range.

mfxInfoVPPstruct **mfxInfoVPP**

Specifies configurations for video processing. A zero value in any of the fields indicates that the corresponding field is not explicitly specified.

Public Members***mfxFrameInfo* In**

Input format for video processing.

***mfxFrameInfo* Out**

Output format for video processing.

mfxVPPCompInputStream

struct **mfxVPPCompInputStream**

Used to specify input stream details for composition of several input surfaces in the one output.

Public Members

mfxU32 **DstX**

X coordinate of location of input stream in output surface.

mfxU32 **DstY**

Y coordinate of location of input stream in output surface.

mfxU32 **DstW**

Width of of location of input stream in output surface.

mfxU32 **DstH**

Height of of location of input stream in output surface.

mfxU16 **LumaKeyEnable**

Non-zero value enables luma keying for the input stream. Luma keying is used to mark some of the areas of the frame with specified luma values as transparent. It may, for example, be used for closed captioning.

mfxU16 **LumaKeyMin**

Minimum value of luma key, inclusive. Pixels whose luma values fit in this range are rendered transparent.

mfxU16 **LumaKeyMax**

Maximum value of luma key, inclusive. Pixels whose luma values fit in this range are rendered transparent.

mfxU16 **GlobalAlphaEnable**

Non-zero value enables global alpha blending for this input stream.

mfxU16 **GlobalAlpha**

Alpha value for this stream. Should be in the range of 0 to 255, where 0 is transparent and 255 is opaque.

mfxU16 **PixelAlphaEnable**

Non-zero value enables per pixel alpha blending for this input stream. The stream should have RGB color format.

mfxU16 **TileId**

Specify the tile this video stream is assigned to. Should be in the range of 0 to NumTiles. Valid only if NumTiles > 0.

mfXVPPStat

struct **mfXVPPStat**

Returns statistics collected during video processing.

Public Members

mfXU32 **NumFrame**

Total number of frames processed.

mfXU32 **NumCachedFrame**

Number of internally cached frames.

Protected Structures

Protected structures.

API

- *mfXExtCencParam*

mfXExtCencParam

struct **_mfXExtCencParam**

Used to pass the decryption status report index for the Common Encryption usage model. The application can attach this extended buffer to the *mfXBitstream* structure at runtime.

Public Members

mfXExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUFF_CENC_PARAM.

mfXU32 **StatusReportIndex**

Decryption status report index.

DECODDE_VPP Structures

Structures used by *DECODE_VPP* only.

API

- *mfXSurfaceArray*
- *mfXVideoChannelParam*
- *mfXExtInCrops*

mfXSurfaceArray

struct **mfXSurfaceArray**

The structure is reference counted object to return array of surfaces allocated and processed by the library.

Public Members

mfXHDL Context

The context of the memory interface. User should not touch (change, set, null) this pointer.

mfXStructVersion Version

The version of the structure.

mfXStatus (*AddRef)(struct *mfXSurfaceArray* *surface_array)

Increments the internal reference counter of the surface. The surface is not destroyed until the surface is released using the *mfXSurfaceArray::Release* function. *mfXSurfaceArray::AddRef* should be used each time a new link to the surface is created (for example, copy structure) for proper surface management.

Parameters **surface** – [in] Valid *mfXSurfaceArray*.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If surface is NULL.

MFX_ERR_INVALID_HANDLE If *mfXSurfaceArray->Context* is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfXStatus (*Release)(struct *mfXSurfaceArray* *surface_array)

Decrements the internal reference counter of the surface. *mfXSurfaceArray::Release* should be called after using the *mfXSurfaceArray::AddRef* function to add a surface or when allocation logic requires it.

Parameters **surface_array** – [in] Valid *mfXSurfaceArray*.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If surface is NULL.

MFX_ERR_INVALID_HANDLE If `mfxSurfaceArray->Context` is invalid (for example NULL).

MFX_ERR_UNDEFINED_BEHAVIOR If Reference Counter of surface is zero before call.

MFX_ERR_UNKNOWN Any internal error.

mfxStatus (***GetRefCounter**)(struct *mfxSurfaceArray* *surface_array, *mfxU32* *counter)
Returns current reference counter of *mfxSurfaceArray* structure.

Parameters

- **surface** – [in] Valid `surface_array`.
- **counter** – [out] Sets counter to the current reference counter value.

Returns

MFX_ERR_NONE If no error.

MFX_ERR_NULL_PTR If `surface` or `counter` is NULL.

MFX_ERR_INVALID_HANDLE If `mfxSurfaceArray->Context` is invalid (for example NULL).

MFX_ERR_UNKNOWN Any internal error.

mfxFrameSurface1 ****Surfaces**

The array of pointers to *mfxFrameSurface1*. *mfxFrameSurface1* surfaces are allocated by the same agent who allocates *mfxSurfaceArray*.

mfxU32 **NumSurfaces**

The size of array of pointers to *mfxFrameSurface1*.

mfxVideoChannelParam

struct **mfxVideoChannelParam**

The structure is used for VPP channels initialization in `Decode_VPP` component.

Public Members

mfxFrameInfo **VPP**

The configuration parameters of VPP filters per each channel.

mfxU16 **Protected**

Specifies the content protection mechanism.

mfxU16 **IOPattern**

Output memory access types for SDK functions.

mfxExtBuffer ****ExtParam**

Points to an array of pointers to the extra configuration structures; see the `ExtendedBufferID` enumerator for a list of extended configurations.

mfxU16 NumExtParam

The number of extra configuration structures attached to the structure.

mfxExtInCropsstruct **mfxExtInCrops**

The structure contains crop parameters which applied by Decode_VPP component to input surfaces before video processing operation. It is used for letterboxing operations.

Public Members***mfxRect Crops***

Extension buffer header. BufferId must be equal to MFX_EXTBUFF_CROPS. Crops parameters for letterboxing operations.

Camera Structures

Structures used by Camera Raw Acceleration Processing.

API

- *mfxExtCamWhiteBalance*
- *mfxExtCamTotalColorControl*
- *mfxExtCamCscYuvRgb*
- *mfxExtCamHotPixelRemoval*
- *mfxExtCamBlackLevelCorrection*
- *mfxCamVignetteCorrectionElement*
- *mfxCamVignetteCorrectionParam*
- *mfxExtCamVignetteCorrection*
- *mfxExtCamBayerDenoise*
- *mfxExtCamColorCorrection3x3*
- *mfxExtCamPadding*
- *mfxExtCamPipeControl*
- *mfxCamFwdGammaSegment*
- *mfxExtCamFwdGamma*
- *mfxExtCamLensGeomDistCorrection*
- *mfxCam3DLutEntry*
- *mfxExtCam3DLut*

mfExtCamWhiteBalance

struct **mfExtCamWhiteBalance**

A hint structure that configures Camera White Balance filter.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_WHITE_BALANCE.

mfU32 **Mode**

Specifies one of White Balance operation modes defined in enumeration mfxCamWhiteBalanceMode.

mfF64 **R**

White Balance Red correction..

mfF64 **G0**

White Balance Green Top correction..

mfF64 **B**

White Balance Blue correction.

mfF64 **G1**

White Balance Green Bottom correction..

mfU32 **reserved[8]**

Reserved for future extension.

mfExtCamTotalColorControl

struct **mfExtCamTotalColorControl**

A hint structure that configures Camera Total Color Control filter.

Public Members

mfExtBuffer **Header**

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_TOTAL_COLOR_CONTROL.

mfU16 **R**

Red element.

mfU16 **G**

Green element.

mfU16 **B**

Blue element.

mfxF32 **C**
Cyan element.

mfxF32 **M**
Magenta element.

mfxF32 **Y**
Yellow element.

mfxF32 **reserved**[6]
Reserved for future extension.

mfxF32ExtCamCscYuvRgb

struct **mfxF32ExtCamCscYuvRgb**
A hint structure that configures Camera YUV to RGB format conversion.

Public Members

mfxF32ExtBuffer **Header**
Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_CSC_YUV_RGB.

mfxF32 **PreOffset**[3]
Specifies offset for conversion from full range RGB input to limited range YUV for input color coordinate.

mfxF32 **Matrix**[3][3]
Specifies conversion matrix with CSC coefficients.

mfxF32 **PostOffset**[3]
Specifies offset for conversion from full range RGB input to limited range YUV for output color coordinate.

mfxF32 **reserved**[30]
Reserved for future extension.

mfxF32ExtCamHotPixelRemoval

struct **mfxF32ExtCamHotPixelRemoval**
A hint structure that configures Camera Hot Pixel Removal filter.

Public Members

mfExtBuffer Header

Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_HOT_PIXEL_REMOVAL.

mfU16 PixelThresholdDifference

Threshold for Hot Pixel difference.

mfU16 PixelCountThreshold

Count pixel detection.

mfU16 reserved[32]

Reserved for future extension.

mfExtCamBlackLevelCorrection

struct **mfExtCamBlackLevelCorrection**

Public Members

mfExtBuffer Header

A hint structure that configures Camera black level correction. Extension buffer header. Header.BufferId must be equal to MFX_EXTBUF_CAM_BLACK_LEVEL_CORRECTION.

mfU16 R

Black Level Red correction.

mfU16 G0

Black Level Green Top correction.

mfU16 B

Black Level Blue correction.

mfU16 G1

Black Level Green Bottom correction.

mfU32 reserved[4]

Reserved for future extension.

mfxCamVignetteCorrectionElement

struct **mfxCamVignetteCorrectionElement**

A structure that defines Camera Vignette Correction Element.

Public Members
